The horses destined for the Circensian courses were preserved entirely for this purpose; and the greatest care was taken to maintain the vigour and purity of the race: their keepers were called *conditores gregis*. It is remarkable, that these horses, as appears by various basso-relievos and mosaics, had their tails cut short. As all the turns round the metæ were made to the left hand, the funarius horse on that side became the leader, and was never changed. The horses were so well accustomed to the contest, that they often ran without the whip. Pliny relates, that once a charioteer, having fallen from his car, the horses performed the course in the usual manner, and gained the palm.

The aurigæ were men accustomed to the employment, who had no other occupation. They were generally slaves, though sometimes persons of rank and fortune exercised this art for their amusement. Nero frequently exhibited himself as a charioteer in the public games. The business of an auriga required great address, agility, and practice, and demanded infinite pains to learn it perfectly. They were dressed in the colour of their faction; but their only cloathing consisted of a light tunic, without sleeves, which did not reach below the knees. They wore a round helmet, fastened under the chin, to defend their heads in case of a fall: the tunic was closely and strongly girded with belts, probably of leather, which covered the chest and stomach. An antique torso at the Museo Pio-Clementino, gives a very clear representation of this part of the costume. A crooked knife stuck among the belts was an essential part of their equipment; for as the reins were fastened round the middle of the driver, he would, if he happened to fall from the chariot, have been exposed to the danger of being dragged round the circus, if he had not had the means of delivering himself by cutting the reins.

Now the charioteers and horses, shut up in the carceræ, eagerly expected the moment of departure. In winter the breath of the horses was seen coming through the lattice of the gates, and they were heard to beat with their hoofs the hardened ground. The prætor gave the first signal, on which the gates of the carceræ were opened all at once by means of some machinery; this signal was different at different times, anciently it was a lighted torch; in the time of Nero a piece of white cloth thrown from above was the signal; at the second and last signal, the sound of a trumpet, a cable which crossed from one herma to another fell, the chariots left the carceræ, and advanced towards the right side of the circus. Tending to the same centre by so many radii, the chariots could not encounter till they entered into the course; but from this time there was a continual struggle and conflict among the cars to obtain the nearest place to the spina, and turn the goals as close as possible. The whole course consisted of seven turns, and he, who after the seventh turn, arrived first at the meta opposite the carceræ was the conqueror. Thus, the object was not only to run as fast as possible, but to shorten the way, by keeping close to the spina, and turning short round the meta, without, however, touching, or even grazing, for the smallest shock would overturn the car. This accident, in Circensian phrase, was called a shipwreck. The charioteers were permitted to clash with and overturn their adversaries, provided it did not happen before they entered into the course, that is, before they had passed the space between the carceræ and the first meta. It appears, that a white chalk line was drawn across the circus, to mark the beginning and termination of the course.

If, in commencing the course, there was reason to suspect any trick, or foul play, it was lawful for the people to require that it should be recommenced: this demand was made by shaking their togas; and when this sign was general, the prætor was obliged to comply.

There were twenty-five courses, as before observed, and the usual number of cars was four; there were, however, exceptions from these rules. At the celebration of the secular games, Domitian, instead of 25, gave 100 courses in one day; but the chariots, instead of seven, made five turns. Commodus frequently had six cars run at once; and on a sepulchral bas-relief at Foligno nine chariots are represented in full career. The victor obtained a palm, and, in later times, a crown. He was called *bravium*, which term is apparently the origin of bravo, and brave, in modern languages. The second and third charioteers were not without some reward, but the fourth had only the disgrace of being vanquished.

After the chariot races, the charioteers ran foot races in the arena; and the athletæ and wrestlers finished the exhibition of the day.

The Roman people were excessively attached to the games of the circus. To this purpose is the verse of Juvenal,

> " — Atque duas tantum res anxius optat,
> Panem et Circenses ——— "

These words *panem et circenses*, formed the cry of the multitude, who frequently remained whole nights and days in the circus, exposed to the weather, and without leaving their places to take any refreshment. At Constantinople this passion was more violent than ever, and the factions of the circus endangered the empire. Bianconi "Descrizione del Circo di Caracalla." "Mosaique d'Italica."

CIRCUS, in *Ornithology*, a name by which Bellonius, Gesner, and Aldrovandus distinguish the moor buzzard, *Falco æruginosus* of Linnæus and later authors. The name circus has been likewise applied to other birds of the falco tribe: Brisson, for example, calls the *Falco gallinarius*, *Circus major*, and the Gmelinian falco brasiliensis, or Brasilian kite, *Circus brasiliensis*.

CIRE', in *Geography*, a town of France, in the department of the Lower Charente, and district of Rochefort; $2\frac{1}{2}$ leagues N. of it.

CIRELLA, a town of Naples, in the province of Calabria Citra, near which were formerly mines of gold, silver, and lead, some traces of which are now visible; 8 miles E.S.E. of Scalea.

CIRENCESTER, or CICETER, a borough and market town of Gloucestershire, England, was formerly the seat of a Roman colony, and is supposed to have been the metropolis of the Dobuni. The circumstance of the junction of the three Roman roads, called the Foss-way, the Irmin-street, and the Icknield-way, on this spot, evinces its eligibility for a Roman station: numerous ancient remains have at various times been discovered, and scarcely a year elapses, but some memorial of antiquity is found in the vicinity. The ancient city was inclosed by a wall and a ditch, the remains of which demonstrate the circumference to have been upwards of two miles. It is supposed that the fortifications were razed soon after Henry IV.'s reign; but that they were not wholly obliterated, appears from the following authorities. Leland observes that "a man may yet, walking on the bank of Churne, evidently perceyve the compace of foundation of towers sumtyme standing in the waul. And nere to the place wher the right goodly clothing mylle was set up a late by the abbate, was broken down the ruine of an old tower,

towards

towards making of the mylle waulles, in the which place was fownd a quadrate ſtone fawllen down afore, but broken in many pieces, wherin was a Roman inſcription, of the which one ſcantlie letterd that ſaw yt, told me that he might perceyve PONT. MAX. Among divers coins found frequently there, Diocleſian's be moſt faireſt." The abbot of Cirenceſter informed Leland that he had found in the ruins arched ſtones, ſculptured with large Roman letters. Hearne obſerves that coins with a figure holding a patera in the right hand, and a palm-branch in the left, were found here in his time; and he had been informed of the diſcovery of a pavement before the year 1711, compoſed of many coloured teſſeræ. Sir Robert Atkyns mentions a ſubterraneous building, fifty feet long, forty broad, and about four high, ſupported by an hundred pillars curiouſly inlaid. Dr. Stukeley mentions a moſaic pavement dug up here in Sept. 1723; and adds, that a vault was diſcovered ſixteen feet by twelve, ſupported by pillars of Roman brick, three feet ſix inches high, on which was a ſtrong floor of terras; ſeveral other vaults adjoining, were ſhaded by cherry trees; and broken pillars, mouldings, cornices with carved medallions, baſes, capitals, &c. were found indiſcriminately ſcattered. Theſe remains have been recently aſcertained to belong to a Roman hypocauſt. A teſſelated pavement, about ſixteen feet ſquare, was found in 1777, beneath a warehouſe in Dyer-ſtreet; another, and more beautiful fragment, was diſcovered in digging a cellar in the ſame ſtreet; and the Bull-ring in the Querns is ſuppoſed to have been an amphitheatre.

The caſtle of Cirenceſter is firſt mentioned in hiſtory as being garriſoned by the earl of Glouceſter for the empreſs Maud againſt king Stephen, by whom it was taken. In the reign of Henry III. it was garriſoned by the barons; but being recovered by the king, he ordered its total demolition. The town, notwithſtanding, appears to have been a place of ſtrength, and is celebrated for the ſuppreſſion of the conſpiracy of the nobles againſt Henry IV. Cirenceſter was formerly celebrated for its rich abbey, which aroſe from a decayed college of prebendaries of ancient Saxon foundation. Rumbaldus, dean of this college, and chancellor to Edward the Confeſſor, witneſſed a grant of that monarch to the abbey at Weſtminſter. Leland mentions a "ſepulchre croſſe," of white marble, as remaining in the abbey church. This building, as appears from Leland and William of Worceſter, was of the Saxon ſtyle of architecture, 280 feet in length, and of proportionable dimenſions. At the diſſolution, the ſite of the abbey was granted to Roger Baſing eſq. on condition that all the buildings within the precincts ſhould be pulled down and carried away; which was ſo effectually executed, that the ſpot occupied by the church cannot now be exactly aſcertained. The ſeat of Thomas Maſter, eſq. now called the abbey, includes the ſite of moſt of the monaſtic buildings. The pariſh church at Cirenceſter, is one of the moſt magnificent parochial edifices in the kingdom. It was completed but a few years prior to the ſuppreſſion of the abbey, yet the regular ſtyle of the fifteenth century prevails in every part. The interior conſiſts of a nave, ſide aiſles, a choir or chancel, and five chapels; at the weſt end is a handſome embattled tower, 134 feet high, ornamented with pinnacles and ſtatues: and on the ſouth ſide is a beautiful porch richly decorated externally with groteſque figures, carved niches, canopies, oval windows, ſculptured cornices, and open-worked battlements; and internally adorned by radiant tracery, ſpreading over the roof in eight circular fan-ſhaped compartments, which riſe from ſingle pillars and meet in the centre, where the lozenges formed by the extremes of the circles, are ornamented with quatrefoils. The porch is 38 feet in length, by 50 in height. The inſide of the church contains two rows of cluſtered columns, five in each; which, with two pilaſters at each end, ſupport the roof. The windows were formerly filled with painted glaſs, but a conſiderable part has been mutilated or miſplaced. Of the chapels, that on the north ſide, dedicated to St. Catherine, is worthy of particular notice, from the ſculptures in the compartments of the roof. In Trinity chapel are two marble monuments, to the memory of Allen, earl Bathurſt, and his ſon the lord chancellor.

Cirenceſter has ſeveral ſchools: the moſt ancient is the free grammar ſchool, founded by biſhop Ruthall, who was a native of this town, and privy counſellor to Henry VII. Queen Mary added 20*l.* to the endowments. Several perſons of eminence have received their education in this ſchool. There are alſo a blue-coat ſchool, and a yellow-coat ſchool, both eſtabliſhed early in the eighteenth century. Among other charitable inſtitutions, are three hoſpitals: St. John's, founded by Henry I.; St. Lawrence's, by Edith, lady of the manor of Wiggold, time unknown; and St. Thomas's, by ſir William Nottingham, attorney-general to Henry IV.

The manufactures of this town ſeem generally in a declining ſtate, with the exception of that for curriers' knives, which are held in high eſtimation throughout Europe and America, and are made by three or four houſes here, by one at Glouceſter, and ſcarcely any where elſe in the kingdom. There are alſo a clothing-houſe, a ſmall carpet manufactory, and two breweries.

The markets, which are held on Monday and Friday, are much frequented, and well ſupplied, eſpecially with corn and meat. Great quantities of wool were formerly brought from Buckinghamſhire, Berkſhire, Northamptonſhire, and Oxfordſhire, and ſold at the Booth-hall, where large rooms were provided for the reception; but the modern practice of dealers travelling to make their purchaſe, has effectually deſtroyed this market. Three fairs are annually held, and two mops, or ſtatute markets, on the Mondays preceding and following the tenth of October. Great numbers of farmers and others attend theſe markets to hire labourers and ſervants, who wear, in their hat or boſom, badges of whip-cord, wool, or cow-hair, thus diſtinguiſhing themſelves as candidates for the offices of carter, ſhepherd, dairy-maid, &c.

The diſtrict called the hundred of Cirenceſter included, at the Domeſday ſurvey, ſeven villages; but Henry IV. made the town a diſtinct hundred, as it ſtill remains, excluding the abbey, almery, and Spiringate lane. He alſo made it a corporate town, to be governed by a mayor, two conſtables, &c.; but his charter was cancelled 37 Eliz. The hundred conſiſts of ſeven wards; the ſteward of the manor annually appoints two high conſtables and two petty conſtables for each ward, with the other neceſſary officers. Repreſentatives were ſent from this borough to a great council 11th Edward III.; but the firſt regular return to parliament was made under a grant of 13 Eliz. Different deciſions of the Houſe of Commons have confined the right of election to the inhabitant houſeholders not receiving alms; the number is about 500.

The town conſiſts of four principal, and ſeven ſmaller ſtreets, with ſeveral lanes, extending over an area of about two miles in circumference. The buildings are chiefly of ſtone; and the more reſpectable houſes are generally detached. The ſtreets, excepting the ſouth ſide, have a gradual declivity from the centre to the extremities. The population has increaſed but little ſince the beginning of the laſt century; the inhabitants amounting then nearly to 4000, and being returned under the act in the year 1801 at 4130; the number of houſes 885. Cirenceſter is ſituated 89 miles W. from London. It is very near to the grand ridge of England; and not far from the famous Sapperton tunnel, by which the Thames and Severn canal crosses it: a short branch of this canal is conducted up to the town of Cirencester. See CANAL.

Ricardus Corinienfis, or Richard of Cirencester, so call'd from being a native of this town, was the compiler of the celebrated Itinerary, part of which, relative to England, was published under his name by Dr. Stukeley.

Oakley Grove, the feat of Henry earl Bathurst, lies on the west of Cirencester. The mansion is only at a small distance from the town, the view of which is intercepted by a lofty wall lined with perennial trees. It was built early in the last century; and, though very spacious, is more convenient than grand. Lysons' Gloucestershire Antiquities. Rudder's History of Gloucestershire. Rudge's History of Ditto, 2 vols. 8vo.

CIRENZA, a town of Naples, in the province of Calabria Ultra, 12 miles N. of Girace.

CIREY, a town of France, in the department of the Meurthe, and district of Luneville, 8 miles E. of Blamont.

CIRIE, a town of Italy, and capital of a marquisate, in the principality of Piedmont, comprehending the towns of St. Maurice, Nolli, and Robasome, seated near the foot of the Grecian Alps, in the Doria; 8 miles N.N.W. of Turin.

CIRIS, in *Ornithology*, the painted bunting of Pennant and Latham, a species of *emberiza*, which see.

CIRKNITZ, in *Geography*, a small village of Carniola, seated on a lake called the "Cirknitz sea," surrounded with steep and rugged mountains; 14 miles S.S.W of Laybach, and 168 S.S.W. of Vienna. In winter this lake is very extensive, and overflows a considerable part of the adjacent fields, which, in summer, are quite dry, and fit for tillage; whence it is commonly said, that a person may sow and reap, hunt and fish, in this lake, within the space of a year. When it is dry the rushes, which it yields in great abundance, are mowed for manure and litter for the cattle; and when it remains long dry, it produces a kind of grass which is used as fodder. The most remarkable circumstance attending this lake is, that it generally continues to ebb for 25 days; the water during that time running off by holes or cavities, which are 18 in number, and are so many eddies or whirlpools. Instances have occurred of its being dried up, by the absorption of these eddies, three times in a year. The lake abounds with fish: and in spring and autumn it is frequented by large flocks of wild ducks. There are three pleasant islands in this lake, besides a kind of peninsula. It is somewhat more than a German mile in length, and about half as broad. Its greatest depth, exclusive of the cavities or holes, is about 24 feet. Strabo calls it Lugea palus, either from the town of Lueg, which lies near it, or from its deep and cavernous bed.

CIRL-BUNTING, in *Ornithology*. See EMBERIZA CIRLUS.

CIRLUS STULTUS, the foolish bunting; *Emberiza cia*, is so named by Aldrovandus and Willoughby; the former calls it likewise *emberiza pratensis*.

CIRNA MONS, in *Ancient Geography*, *Dghibbal Ifkol*, a mountain of Africa, S.W. of the Hipponites lake, and 5 leagues from the town of Hippozaritus. It is mentioned by Ptolemy, and distinguished by its round figure.

CIRO, in *Geography*, a town of Calabria, standing on the site of Crimissa, a city founded by Philoctetes, the friend and heir of Hercules. This is a very poor place, though it contains about 6000 inhabitants; it belongs to Spinelli, prince of Tarsia, who monopolizes all the silk made by his vassals. The territory produces also very fine oil and corn, bad wine but good water.

CIRPHIS, in *Ancient Geography*, a town of Greece, in the Phocide territory. Strabo places it near Mount Parnassus.

CIRQUINCON, in *Zoology*, the name under which Buffon describes the weazel-headed armadillo, *dasypus 18-cinctus* of Linnæus, and *tatu mustelinus* of Ray.

CIRRADIA, or CIRRHADIA, in *Ancient Geography*, a canton of India, on the other side of the Ganges, according to Ptolemy, who says that it yielded the best *malabathrum*. M. d'Anville places it towards the 26th degree, on the course of the river Catabeda.

CIRRHA, a maritime town of the Phocide territory, seated on the gulf of Corinth, and serving as a port to the town of Delphi, and 60 stadia distant from it. On an adjoining plain was an hippodrome, dedicated to Apollo. Homer calls this town Crissa. We learn from Pausanias, lib. ii. c. 37, that Cirrha had a beautiful temple of Apollo, Diana and Latona, in which were large statues of these deities, which belonged to the school of Athens.

CIRRHOSE, in *Botany*, a term applied to the leaves or other parts of a plant, when they throw out cirrhi or tendrils, by which they cling to neighbouring plants or other bodies.

CIRRI, GIOVANNI BATTISTA, in *Biography*, a native of Italy, whose instrument was the violoncello, upon which he was a more useful than shining performer. He was a regular bred musician, a good contrapuntist, and wrote correctly for several instruments besides his own. He resided in England many years. His first work was published at Verona in 1763, where he is styled *professore di violoncello*, born at Forli. In 1785 he had published in London, Paris, and Florence, 17 different works, consisting of quartets, trios, solos for his own instrument, and pieces for the organ.

CIRRIS, in *Ornithology*, one of the synonymous names of the long-legged plover, *charadrius himantopus*. Cirris is the name under which it is described by old writers; it was formerly considered as appertaining to the ardea or heron tribe, but is certainly by no means related to that genus. The general plumage of this bird is white, with the wings blackish and glossed with shining green; the legs a very beautiful red. The species is occasionally found in England. Donov. Brit. Birds, &c.

CIRRUS, in *Antiquity*, an ornament added to the edges and borders of garments, much in the manner of fimbriæ or fringes, only that these were single and run along the borders of the dress; whereas the cirri were knotted together, and hung down from the extremities of the robe.

CIRRUS, in *Botany*, a tendril or clasper, by whose numerous convolutions plants lay hold of other bodies for support. The name refers to the naturally curling locks of a child after they have been once cut, called by the Romans previously *comæ*, but afterwards *cirri*, most probably from κειρειν, *to shear*. Some of the old botanists used the name of *cirri* for the *stamina*, and others for the fibrous crown of the root, formed of the remains of leaf-stalks in several plants, as *Meum athamanticum*. Linnæus, who first applied this term to tendrils, writes it *cirrhus*. Haller retained the old names of *capreolus* and *claviculus* for the part in question. See CAPREOLUS and CLAVICULUS

Tendrils are enumerated by Linnæus among those appendages to a plant which he denominates *fulcra*, or props, and of which he reckons seven kinds. They are the only one of the seven to which the term he has chosen can, with strict propriety, be applied. They serve to support weak and climbing stems upon such as are strong and upright, and they are most abundant in annual stems, Bryony and the Vetch kind for instance, which springing from strong and durable roots, thrive with great luxuriance during summer, decorating with their foliage, blossoms and fruit, many, otherwise otherwife naked, ftems and branches; till, having perfected their feeds, they no longer encumber the face of nature, and their living principle fhrinks, as it were, into its winter quarters in the root. In the forefts of India and America the climbers are often of a more fhrubby kind, and afcend to the tops of the higheft trees, affifted frequently by twining ftems as well as by the organs in queftion.

Tendrils generally grow ftraight, and more or lefs horizontally at firft, but their extremities foon affume a fpiral fhape, and make a certain number of turns, which being accomplifhed, they, in many inftances, perform about as many more in the contrary direction, and even afterwards refume their original one, by which they have fo much the more chance of catching hold of any neighbouring branches. Some of them, as in *Vicia* and *Lathyrus*, are repeatedly branched, rendering the chances ftill more in their favour; while others are perfectly fimple, and turn but in one direction, as thofe of *Gloriofa fuperba* and *Flagellaria indica*, which are merely a fpiral elongation of the points of their leaves, hence denominated *folia cirrofa*. In many pinnated leaves, particularly thofe of the Vetch tribe, a *cirrus*, either fimple or branched, terminates the common foot-ftalk, the leaves thus circumftanced being, of courfe, abruptly pinnated. When the *cirrus* is quite diftinct from the leaves, it is ufually axillary, as in the genus *Paffiflora*; fometimes it proceeds from the flower-ftalk, as in *Cardiofpermum halicacabum*, and *Annona hexapetala*, *Linn. Suppl.* 270. The extremity of the flower-ftalk in the latter forms a hook, which embraces the branch, and gathering great ftrength after the flower is paft, ferves to fufpend the large and heavy fruit refembling a bunch of grapes, for which purpofe the bafis or receptacle of the flower does not perhaps poffefs fufficient firmnefs.

Profeffor Willdenow has an idea that *cirri* are, "in fact, *petioli* without the leafy expanfion, but which, not having wafted their fap in the formation of leaves, have grown the longer, and thus have become too thin and feeble to preferve their ftraight direction." The obfervation of the leguminous plants favours this hypothefis, the branches of whofe tendrils actually feem each to have taken the place of a leaflet. So alfo the *Gloriofa fimplex*, a plant obferved by Miller alone, and now generally fuppofed to have been a mere variety of *G. fuperba*, deficient in the fpiral appendage to its leaf, may be prefumed to have beftowed all its vigour in the expanfion of the leaf itfelf, without accomplifhing more. But the *cirri* in *Paffiflora*, *Vitis*, *Bryonia*, *Cucumis*, &c. are, unqueftionably, diftinct organs, which never affume the forms nor functions of leaves.

Willdenow further remarks, that "it appears as if the diminifhed force of the current of air had fome influence upon the tendril. For each plant that fupports itfelf by tendrils, when diftant from a wall, tree, or fhrub, fends out all its tendrils towards that fide on which the plant is to attach itfelf." This feems to us not fatisfactory. If the fact be true, for which we cannot vouch, it is rather to be explained by this ingenious writer's preceding theory, that part which, if fituated where it had received more air and light, would naturally have expanded into a leaf, being in oppofite circumftances contracted into a tendril. We are perfuaded, however, that, except poffibly in the above-mentioned leguminous plants, the *cirrus* and the leaves are organs totally diftinct in their nature. The latter are ftimulated to expand by the action of light and air, and prefent themfelves fo as to receive thofe ftimulants; the former feem to thrive moft from refiftance, and to court that refiftance, turning with much more vigour round any extraneous body than in a void fpace. So the tendrils of *Hedera quinquefolia*, properly a fpecies of *Vitis*, when they attain the trunk of a tree, or the even furface of a ftone, efpecially a fmooth flint, no fooner fix upon it than their extremities dilate, clinging with a fort of appetency to what feems to ftimulate them to an extraordinary exertion. Much the fame thing may be obferved in our common ivy, *Hedera helix*.

Tendrils feldom afford good fpecific characters, being too much alike in the fame genus to anfwer any fuch purpofe. In the various climbing fpecies of Virgin's-bower, *Clematis*, there are no real *cirri*, but the leaf-ftalks effectually perform their functions, efpecially in the beautiful *C. cirrofa*, where thofe ftalks are permanent, for a year at leaft, after their leaves are fallen, and having all the appearance of naked *cirri*, feem to have been taken for fuch by Linnæus. Hence Juffieu was induced, in the Paris garden, to change the name of this fpecies to *pyrifolia*; but the femblance of *cirri* is fufficient to juftify the original denomination, though the Linnæan fpecific character requires correction. S.

Cirrus, Cirri, in *Ichthyology*, the Linnæan term applied in general to the beard, or foft *appendiculæ* which hang about the mouth or jaws of fifhes; it is alfo occafionally employed to exprefs the fkinny or flefhy appendages about other parts of the body. See Ichthyology.

CIRSELLIUM, in *Botany*, a genus formed by Gærtner, for fome fpecies of the Atractylis of Linnæus, with the following character. *Calyx* imbricated either with fpinous, or with fpinelefs fcales. *Receptacle* befet with briftly chaff. *Florets* of the difc hermaphrodite; of the ray feminine, ftrap-fhaped; both fertile. *Seeds* uniform; down feathered. He refers to it, Atractylis cancellata and humilis, and doubts whether A. gummifera, lancea, ovata, with Carthamus folicifolius, ought not to be added.

CIRSIUM, in *Botany*, (Circium; Tourn.) a genus taken up by Gærtner, with the following character. *Calyx* bellying or cylindrical, imbricated; fcales acuminate, either with, or without prickles, but never with appendicles. *Florets* all hermaphrodite. *Receptacle* chaffy; *feeds* crowned with a feathery down; rays of the down filiform, nearly equal, united into a ring at the bafe. The Cirfium and Cirfellium of this author differ only in the former being without, and the latter with a ray.

CIRSOCELE, in *Surgery*, corruptly written Circocele, from κιρσος *varix*, and κηλη, *tumor*; fometimes called *Hernia varicofa*, though improperly, as it has no affinity to a real Hernia, which fee.

The cirfocele is an unequal and irregular enlargement of the fpermatic veffels, near the teftis in which are felt, as it were, hard ftrings or varicofe veins, of the thicknefs of a quill or even larger, involved together like a mafs of worms, and preffing down upon the tefticle. The diforder is moft common in young plethoric men, and in thofe efpecially who are unmarried. It is more troublefome than dangerous, and feldom requires any other attention than wearing a bagtrufs to fupport the part.

The tumor is generally firft difcovered near the bottom of the fcrotum; in moft cafes it makes a gradual progrefs. At its commencement, the patient perceives a fenfe of weight in the fcrotum; which, as the difeafe increafes, becomes more fenfible, but diminifhes in its bulk upon the application of a fufpenfory bandage, or when the patient lies upon his back. When the tumor is fqueezed, the patient feels that peculiar fenfation, which always is produced by preffure applied to the tefticle. At length the tumor gradually enlarges upwards, approaches the abdominal ring, widens it, and alters its fituation or form; fo that nothing but a confufed irregular mafs can be difcovered upon examining this part.

The cirfocele may be thus diftinguifhed from the omental hernia, with which it has fome fimilarity in its advanced ftate:

ſtate: viz. The omental hernia deſcends from the abdominal ring downwards, whilſt the cirſocele always commences at the bottom of the ſcrotum, and increaſes upwards. It alſo comes on very gradually, and is not attended by thoſe ſymptoms which accompany the omental hernia in conſequence of the omentum dragging down the inteſtines. The maſs which forms the cirſocele can never be puſhed into the abdomen, whereas the protruded omentum frequently may be returned. In the cirſocele, the teſticle often diminiſhes in ſize, and even waſtes entirely away; whilſt in the omental hernia, it is found to be perfect and ſound. Finally, when the tumor in an omental hernia is preſſed as above mentioned, the patient experiences no peculiar ſenſation or pain; whilſt in the cirſocele, pains are frequent even without any apparent cauſe.

The cirſocele may be diſtinguiſhed from the hydrocele, with which it has alſo much ſimilarity, by the following circumſtances: In a ſimple hydrocele, the teſticle and the epidydymis are perfectly natural and ſound, whilſt in the cirſocele theſe parts are always found to have ſome preternatural and irregular conformation: the tumor in the hydrocele is alſo of a more pyramidal figure, and when the patient lies down or ſtands up it yields to preſſure, and riſes upwards; and as ſoon as the preſſure is removed, recovers its former ſituation. Moreover in the hydrocele, the patient does not feel pain in the ſcrotum, or even in the tumor itſelf, as in the cirſocele, but merely in the region of the groin: the more the hydrocele increaſes, the more the teſticle is concealed, and can only be felt at the bottom; but when the diſeaſe has attained its height, it entirely diſappears, as in the cirſocele. Finally, the elaſticity and fluctuation perceived upon preſſing the tumor between the fingers, are ſymptoms by which the hydrocele may readily be diſtinguiſhed from the cirſocele.

The cirſocele is frequently combined alſo with other diſeaſes of the male organs of generation, from which however it may readily be diſtinguiſhed.

The cauſes of this diſeaſe are: hypochondriaſis, obſtructions or irregularities of the hæmorrhoidal diſcharge, immoderate laſciviouſneſs, redundance of ſemen, &c. The diſeaſe conſiſts in a tumefaction of the ſmall veſſels compoſing the teſticle, which protrude out of the proper membrane of the teſticle, and mix themſelves with thoſe of the epidydymis. Frequently the diſeaſe is occaſioned by preſſure on the upper part of the ſpermatic chord by a rupture-bandage, or a ſcirrhous tumor. (See the article TRUSS.) Sometimes it is occaſioned merely by a relaxation of the veſſels of the ſpermatic cord; in which caſe a ſuſpenſory bandage, the horizontal poſture, cold bathing, and the external application of a ſolution of alum produce beneficial effects. When theſe remedies do not entirely remove the tumor, they at leaſt check its further progreſs.

The mode of cure ought properly to be regulated according to the different cauſes that have produced the diſeaſe. Antiphlogiſtic remedies are chiefly to be employed. (See INFLAMMATION.) Above all, the patient ſhould keep in a horizontal poſture, and uſe a ſpare diet. In proportion to the ſtrength of the ſubject, local bleeding muſt be employed, and ſometimes repeatedly. Emollient and anodyne glyſters, as alſo gentle and cooling laxatives, are likewiſe ſerviceable. The ſcrotum ſhould be conſtantly ſupported by a ſuſpenſion bandage; and water cooled with ice may be frequently daſhed over it, in order to reſtore the tone of the parts.

Some of the ancient ſurgeons have recommended to lay the diſeaſed parts bare, and either to tie or extirpate the tumefied veins; but probably when obſtructions of the hæmorrhoidal veſſels have cauſed this diſeaſe, it might be effectual, without laying bare the ſpermatic chord itſelf, merely to apply leeches under the abdominal ring, and thus produce a topical evacuation of blood. The advantage of this practice is the more to be expected, as it is known that the ſpermatic veins anaſtomoſe with the veins of the external ſurface.

Should all the remedies we employ be of no effect, we are told there may be even danger of cancer, and that caſtration muſt follow; but this operation ſhould not be haſtily performed, as we have never ſeen any ſuch conſequences, and are inclined to doubt the propriety of this advice in any caſe of ſimple cirſocele. (See CANCER.) The doctrine of cirſocele terminating in cancer, has particularly been inſiſted on by the German ſurgeons.

CIRSOPHTHALMIA, from κιρσος, *varix*, and οφθαλμια, Ophthalmia varicoſa, varicoſitas conjunctiva: a varicoſe dilatation of the veſſels of the tunica conjunctiva. In this diſeaſe there appear red varicoſe veſſels diſtended with blood upon the tunica conjunctiva of the eye: they are generally in the form of bundles, uniting commonly near to one of the angles of the eye, where they form a kind of trunk, on which account this diſeaſe has ſometimes been termed *Ophthalmia angularis.* At the point where the ſmall veſſels join, a ſmall tubercle is obſerved, which is actually varicoſe; ſometimes this tubercle burſts and is changed into a ſmall troubleſome ulcer. From the angles of the eye the veſſels ſpread themſelves further towards the cornea, and diverge more from each other; ſometimes ſeveral of them croſs the cornea, and ſenſibly impede viſion, or in ſome inſtances entirely obſtruct it. (See OPHTHALMIA.)

Theſe veſſels may now and then be made to diſappear by the long-continued external application of cold water, or a ſolution of alum in water, a ſolution of white vitriol, or a weak ſolution of pure kali, &c. The laſt mentioned remedies are to be applied ſeveral times a day, by means of a ſmall hair-pencil, or a few drops of them let fall into the eye.

Mr. Janin recommends an ointment containing white precipitate of mercury, &c. When the ſmall point at which the veſſels of the bunch unite, has already changed into a ſmall ulcer, the ſame remedies are to be uſed as in other ulcers of the conjunctiva: but when theſe remedies are inſufficient, the veſſels muſt be cut through with the point of a cataract knife or lancet; and in order that the divided veſſels may not reunite, they muſt be cut completely through, and the inciſion repeated ſeveral times in the ſame line, ſo that it may penetrate quite through the conjunctiva coat, and the ends of the veſſels muſt be removed from each other with the point of the knife. It is alſo proper that the inciſion ſhou'd be made ſomewhat longer than the breadth of the bunch, as in that caſe, the ends of the veſſels may be more eaſily removed from each other. Should the veſſels re-appear after a few days, the operation muſt be repeated, their bleeding ſhould be promoted by bathing them with warm water, and we may afterwards apply a ſolution of white vitriol, or ſome other aſtringent remedy.

CIRSOTOMY, from κιρσος, *varix*, and τεμνω, *ſeco*, the operation for varices. This operation was formerly in uſe for evacuating the contents of deep-ſeated varices; and is ſtill ſometimes practiſed. (See VARIX.) The teguments over the varix are cut open, and the varix ſeparated from the ſkin and neighbouring parts, by means of a probe or other blunt inſtrument; after which the vein is tied above and below the varix, in the ſame manner as the artery in caſes of aneuriſm. See ANEURISM.) The tumor, ſituated between the two ligatures, ſeparates itſelf together with the ligatures in the courſe of a few days; or we may divide it at firſt, or only ſeparate its anterior part with the ſciſſars. When the varix is ſituated near

near to a bone, it is not neceſſary to tie the vein; but as ſoon as the integuments have been divided we may immediately extirpate the whole tumor, and ſtop the hæmorrhage by compreſſion upon the bone. When the ſkin, as ſometimes happens, adheres ſo ſtrongly to the varix that it cannot be ſeparated, we muſt cut out the adhering portion. If the operation has been performed by ligature, we muſt wait for the ſeparation of the threads, and then promote the union of the wound. Now and then this operation has been followed by inflammation, and even death!

CIRTA, or CIRTHA, in *Ancient Geography*, a town of Africa in Numidia, or in the eaſtern province of Algiers, now called Conſtantina, anciently the Mauritania Cæſarienſis. It derived its name, according to Bochart, from קרתא *cartha*, *i. e.* city; which denotes that it was formerly a conſiderable place. It was ſeated on an eminence, about 48 miles from the ſea, and became the capital of the kingdom of Numidia, and the royal reſidence. Its magnitude and ſtrength may be inferred from the extent of its ruins, and from its particular ſituation; the greateſt part of it being built upon a peninſular promontory, inacceſſible on all ſides, except towards the S. W. where it was joined to the continent. This promontory was computed by Dr. Shaw (Trav. p. 60.) to be a good mile in circuit, lying a little inclined to the ſouthward, but towards the north it terminated in a precipice, at leaſt 100 fathoms perpendicular, from whence is a beautiful landſkip, over a great variety of vales, mountains, and rivers, which lie to a great diſtance before it. Eaſtward the proſpect is bounded by an adjacent range of rocks much higher than the city; but towards the S. E. the country is more open; and in this direction the peninſular promontory is ſeparated from the continent by a deep narrow valley perpendicular on both ſides, where the Rummel or Ampſaga conveys its ſtream. The neck of land to the S. W. where ſtood the principal gate of the city, is about the breadth of half a furlong, being entirely covered with broken walls, ciſterns, and other ruins, which are continued quite down to the river; and carried on from thence over a ſtrip of plain ground, that runs parallel with the abovementioned valley. The preſent city has not the ſame dimenſions, being confined to the peninſular promontory only. Near the centre of the city there ſtill remain thoſe capacious ciſterns which received the water brought thither from Phyſgeah by an aqueduct, a great part of which ſubſiſts and is very ſumptuous; they are about 20 in number, and form an area of 50 yards ſquare. The gate conſiſts of a beautiful reddiſh ſtone, not inferior to marble, well poliſhed and ſhining; an altar of pure white marble makes part of a neighbouring wall, and the ſide in view preſents a well ſhaped ſimpulum in a bold relief. The gate towards the S. E. reſembles the other, though ſmaller, and lies open to a bridge that was built over this part of the valley; the bridge is much extolled; the gallery and columns of the arches being adorned with cornices and feſtoons, ox-heads and garlands. The key-ſtones of the arches are charged with caducci and other figures. Below the gallery, betwixt the two principal arches, is ſeen in bold relief, well executed, the figure of a lady treading upon two elephants, with a large eſcallop ſhell for her canopy. Below the bridge the Rummel turns towards the north, and runs near a quarter of a mile through a rocky ſubterraneous paſſage, laid open in ſeveral places for the convenience of drawing up the water, and cleanſing the channel. To the S. W. of the bridge is ſeen among the ruins the greateſt part of a triumphal arch called "Coſſir Goulah," or the caſtle of the giant, conſiſting of three arches, the mouldings and frizes of which are curiouſly embelliſhed with the figures of flowers, battle-axes, and other ornaments. Under the great precipice without the precincts of the city, are ſeveral ſepulchral inſcriptions, one of which is upon a "Cippus" with the figure of a loaded beeve in baſſo relievo above it, and of a crab below it. Beeves are ſtill uſed in Numidia as beaſts of burden. The Rummel at a ſmall diſtance falls in a large caſcade from its ſubterraneous channel, and above it lies the higheſt part of the city, from whence criminals are precipitated into the river, as they uſed to be in former times.

This place was very conſiderable in the time of Syphax. Strabo ſays, that Micipſa eſtabliſhed in it a colony of Greeks; and it afterwards became ſo flouriſhing as to be able to raiſe 10,000 horſe and 20,000 foot. After the conqueſt of Numidia by the Romans, Sittius Nucerinus revolted againſt the republic, made himſelf maſter of it, and gave it his name, "Cirta Sittianorum." Upon Cæſar's carrying his arms into Africa, it revolted to the republic, which ſent a colony thither, and the city took the name of "Cirta Julia." This city having been ruined A. D. 311 by the conqueſts of the tyrant Alexander, was re eſtabliſhed by order of Conſtantine the Great, and aſſumed the name of "Conſtantina." Juſtinian repaired its fortifications. The name of Conſtantina is ſtill preſerved in the weſt; but the people of the country call it Cucuntia. Count Caylus has engraved the veſtiges of an ancient tomb which are ſtill to be ſeen near this city. Mem. de Lit. t. xxvi. p. 334.

CIRTIPUR, in *Geography*, a city of India in the kingdom of Nepal, ſeated on a hill of the ſame name, containing about 8000 houſes, about a league's diſtance from Catmandu. The inhabitants of this town vigorouſly reſiſted the repeated attacks of the king of Gorcha; but, after a ſiege of ſeveral months, the army of the enemy was treacherouſly introduced into the town; and the people, on the faith of promiſed amneſty, ſurrendered themſelves priſoners. In ſhameful violation of this promiſe, an order was iſſued to put the principal inhabitants to death, and to cut off the noſes and lips of every one, even infants, who were not found in the arms of their mothers; and it was likewiſe required that the noſes and lips which had been cut off ſhould be preſerved, for the purpoſe of aſcertaining how many ſouls they were; and that the name of the town ſhould be changed into "Naſkatapur," ſignifying "the town of cut-noſes." The order, it is ſaid, was carried into execution with every mark of horror and cruelty, none eſcaping but thoſe who could play on wind-inſtruments; although father Michael Angelo, who, without knowing that ſuch an inhuman ſcene was exhibited, had gone to the houſe of the perſon who had received the ſavage order, and interceded much in favour of the poor inhabitants. Many of them put an end to their lives in deſpair; others applied to the Roman miſſion for medicines; "and it was moſt ſhocking," ſays father Giuſeppe, prefect of the miſſion, "to ſee ſo many living people with their teeth and noſes reſembling the ſkulls of the deceaſed." Aſiatic Ref. vol. ii. p. 319.

CIS, a hill of Paleſtine, in the tribe of Juda, ſituated at the N.W. of the Dead Sea, at ſome diſtance from the mouth of the brook Cedron.

CISALPINE, any thing on this ſide the Alps.

The word is formed from the prepoſition *cis*, on this ſide, and *Alpes*; which, though properly confined to the mountains ſeparating Italy and France, yet is uſed by authors for any very high mountains.—Thus Auſonius ſpeaks of the Alps of the Pyreneans, the Alps of the Apennines, &c.

The Romans divided Gaul and the country now called Lombardy into *Ciſalpine* and *Tranſalpine*.

That which was *Ciſalpine*, with regard to the Romans, is *Tranſalpine* with regard to us. See GALLIA.

Cis-

Cisalpine, (rather *Tranſalpine*, or *Paduan*), or as it has been ſince denominated, the Italian *Republic*, in *Geography*, a new ſtate formed by the union of thoſe governments which had been denominated Ciſpadane and Tranſpadane, from their ſituation on the right and left ſides of the Po, created by the French republic in the year 1796, firmly eſtabliſhed in conſequence of the peace of Campo Formio in 1797, by the 8th article of that treaty, further re-eſtabliſhed by the 12th article of the treaty of Luneville in 1801, and acknowledged by his majeſty the emperor, the kings of Sardinia, Spain, Switzerland, the pope, &c. It comprehends by the 8th article of the treaty of Campo Formio, beſide the whole of Auſtrian Lombardy, and part of the former republic of Venice, to the eaſt and ſouth of the Legner, the Bergameſque, the Breſcian, the Cremoneſque, the Modeneſe, the principality of Maſſa and Carrara, and the three legations of Bologna, Ferrara, and Romagna. In a "Geographical and Statiſtical Account of the Ciſalpine Republic, &c." tranſlated from the German by Dr. Oppenheim, 8vo. 1798, the whole territorial dimenſions of the Ciſalpine Republic are ſtated to contain 3,567 ſquare miles, and 3,447,384 ſouls; *viz.*

	Sq. Miles.	Inhabitants.
1. The Duchy of Milan - -	811	1,116,892
2. The Duchy of Mantua 3. The principalities of Caſtiglione and Salferino - -	185	207,331
4. The acquired provinces formerly belonging to the Republic of Venice, *viz.* the Bergameſco, the Breſciano, and the territories of Verona and Rodigo, ſituated on the right bank of the Adige, the White Canal, the Tartaro, the canal Poliſella, and the Po -	463	666,000
5. The Duchy of Modena, with the principalities of Maſſa and Carrara	431	460,000
6. The lands obtained from the duke of Parma, the duchy of Guaſtillo, Sabionetta, and Bozzolla -	27	18,000
7. The three legations, Ferrara, Bologna, and Romagna, formerly Papal - - - - -	1152	775,861
8. The territories of the Griſons, belonging to Worms, Cleves, and the Valteline - -	324	100,000
9. The four (commonly called) Italian Bailiwicks - - - - -	174	103,000
Total - -	3,567	3,447,084

The conſtitution of this republic was eſtabliſhed at a conſulta, aſſembled at Lyons in January 1802, when the name of Italian republic was ſubſtituted for that of *Ciſalpine*, and the magiſtracy was veſted in Buonaparte, the firſt conſul of France, who attended on the occaſion. This conſtitution declares the catholic religion, apoſtolic and Roman, to be the religion of the ſtate; and though it has merely the name of a republic, under the deſpotic government of Buonaparte, the ſovereignty was pronounced to reſide in the whole body of the citizens. The territory of the republic is divided into diſtricts, departments, and communes. The rights of citizenſhip belong to thoſe who are born of Ciſalpine fathers, and reſide in the republic. Strangers holding landed property, or being concerned in commercial or manufacturing eſtabliſhments, and who have reſided ſeven years, may be naturalized; and alſo perſons of eminent talents, by a ſpecial act of favour.

There are three electoral colleges; the college of the poſſidenti, of the dotti, and of the commercanti. They are to meet once in two years at leaſt, on the invitation of the government, to complete their number, to appoint the members of the conſulta, of the legiſlative body, of the tribunal of reviſion and appeal, and the commiſſaries of finance. Their ſeſſion is to continue fourteen days. They are to deliberate, but not to diſcuſs. Their determinations are to be by ſecret ballot; and one-third of the members conſtitute a houſe. The members of the colleges forfeit this right, 1ſt, by bankruptcy; 2d, by abſence during three ſucceſſive ſeſſions; 3d, by accepting any employment under a foreign government; 4th, by continuing in a foreign country ſix months after being recalled.

The college of poſſidenti conſiſts of three hundred citizens, choſen from ſuch as poſſeſs an annual income, from land, of 8000 livres at leaſt. The place of its meeting, for the firſt ten years, is Milan. Every department may ſend members to this college in the proportion of one to thirty thouſand inhabitants.

The college of the dotti conſiſts of two hundred citizens choſen from amongſt the moſt eminent in the arts, ſciences, and various branches of literature. Its place of meeting, for the firſt ten years, is Bologna.

The college of commercanti conſiſts of two hundred citizens, alſo choſen (as the name imports) from among commercial men.

The cenſurati is a committee of twenty-one members nominated by the colleges, of whom ſeventeen is a quorum. Its ſitting is only for ten days.

The government reſides in the preſident, vice-preſident, a conſulta of ſtate; in the miniſters and legiſlative body. The preſident retains his office for ten years, and is re-eligible. With him all laws originate; and he has the ſole conduct of all diplomatic negociations. He is excluſively inveſted with the whole executive power. He appoints the miniſters, the civil and diplomatic agents, the chiefs of the army, &c. He nominates the vice-preſident, who is to repreſent him in his abſence. The vice-preſident, once appointed, cannot be diſmiſſed during the preſidency of him by whom he was appointed. The ſalary of the preſident is 500,000 livres of Milan, of the vice-preſident, 100,000.

The conſulta of ſtate conſiſts of eight perſons, above the age of forty, elected for life by the colleges; one of its members is to be miniſter of ſtate for foreign affairs. This conſulta is charged with every matter relative to foreign affairs. Nothing comes, however, under their deliberation except what the preſident chooſes. In caſe of a vacancy, the conſulta elects a new preſident, and cannot ſeparate till the choice is made. Their ſalaries are 30,000 livres each.

The legiſlative council cannot be compoſed of leſs than ten members, above the age of thirty. They are appointed by the preſident, and may be diſmiſſed by him at the end of three years. They have a deliberative voice on the projects propoſed by the preſident, and are ſpecially charged with drawing up the projects of laws. Their ſalary is 20,000 livres each.

The legiſlative body is compoſed of ſeventy-five members, of above thirty years of age, choſen by each department according to its population. One half is to be taken from the colleges. One third goes out every two years. The going out of the firſt and ſecond third to be determined by lot. The government convokes and prorogues the legiſlative body; but the ſeſſion cannot be leſs than two months annually. The ſalary of the members 6000 livres of Milan.

The

The tribunals, civil and military, are on the model of the French. The judges are for life.

The members of the colleges, the cenfurati, the prefident, vice-prefident, confulta of ftate, are not refponfible. The minifters are refponfible.

The freedom of religious worfhip is declared; and no impediments are admitted to induftry and commerce, but thofe founded in law. No armed body can deliberate. The purchafers of national property are protected. The church is to be maintained out of a portion of the national property. The confulta may, at the end of three years, propofe any alteration in the conftitution.

CISAMUS, or CISAMUM, in *Ancient Geography*, a town placed by Ptolemy in the northern part of the ifle of Crete, and, according to Strabo, the port of the town of Aptera. In the Notitia of Hierocles, it is an epifcopal town.

CISEAUX, or rather CISEAUX DU MINEUR, in *Military Language*, inftruments like chiffels, which miners make ufe of for loofening the earth, and trimming the fides of their excavations, and which, to avoid being heard, they ftrike with the hand.

CISERUSA, or CISSERUSSA, in *Ancient Geography*, an ifland of the Ægean fea, near that of Cnidos. Pliny.

CISIPADES, a people of Africa, who occupied the weftern fide of the Greater Syrtis, according to Pliny.

CISLEU, in *Chronology*, the ninth month in the ecclefiaftical year, and the third in the civil or political year among the Hebrews, containing 30 days: it anfwers to part of our November and December. An annual faft is obferved by the Jews to this day on the 18th of this month, in commemoration of the taking of Jerufalem by Nebuchadnezzar.

CISMAR, in *Geography*, a town of Germany, in the duchy of Holftein, not far from the Baltic; 17 miles N. of Travemunde. N. lat. 54° 14′. E. long. 11° 2′.

CISME. See CHISME.

CISMONE, a river of the country of Tyrol, which runs into the Brenta, near Kofel.

CISNER, CLAUDIUS, in *Biography*, a learned German, born in 1529. He ftudied firft at Heidelberg, and afterwards at Strafburg, where he imbibed the Lutheran tenets under Martin Bucer. At Wittemberg, he was made profeffor extraordinary of moral philofophy. He afterwards ftudied the law in different cities in France, and took the degree of doctor of laws at Pifa in 1559. He foon after returned to Heidelberg, and was nominated profeffor of the pandects, and counfellor to the elector-palatine. He died in 1583. Cifner was author of many works, but the principal was his "Opufcula Hift. et Polit. Philog. diftributa in Libros IV." This collection contains feveral curious tracts on German hiftory, together with poems, orations, and epiftles.

CISPADANA, in *Ancient Geography*, an epithet ufually annexed by the Romans to Gallia, when they wifhed to denote, in Gallia Cifalpina, that part which was fituated, with regard to Rome, on this fide of the Po, or Padus. See GALLIA.

CISPIUS, the name, according to Feftus, of one of the fix hills of Rome, which formed the Efquiline mount. Varro fays, that Cifpius had feven fummits near the temple of Juno Lucina.

CISSA, an ifland of the Adriatic, according to Pliny, and the Notitia Imperii.

CISSA, CRISSA, or CRESSA, a town in the Thracian Cherfonefus, upon the river Ægos, which no longer fubfifted in the time of Pliny.

CISSA, a river of Afia, in Pontus Cappadocia, according to Ptolemy.—Alfo, a fountain of Greece, in the Peloponnefus, placed by Paufanias near Mantinæa.

CISSÆI, a people placed by Diodorus Siculus in Media.

CISSÆRO, or CISSERON, a mountain of Paleftine.

CISSAMPELOS, in *Botany*, (κισσαμπελος, Diofc. *vine of ivy*.) Linn. Gen. 1138. Schreb. 1555. Juff. 285. (Caapeba, Plum. Gen. tab. 29. Pareire, Lam. and Poiret in Encyc.) Clafs and ord. *Dioecia monadelphia*. Nat. ord. *Sarmentaceæ*, Linn. *Menifpermæ*, Juff.

Gen. Ch. Male. *Cal.* perianth four-leaved; leaves lanceolate, obtufe, concave, fpreading, coloured. *Cor.* none. *Stam.* filaments five, united, inferted into the nectary; anthers fhort, four-lobed. *Nectary* fhorter than the calyx, membranous, entirely coloured, a little concave, wheel-fhaped, occupying the centre of the flower. Female. *Calyx* one-leafed, opening laterally in the fhape of an oval fpathe, narrowed at its bafe, inferted into the lower part of the germ. (Linnæus confiders it as a bracte.) *Cor.* one-petalled, egg-fhaped, obtufe, convex, caducous, opening laterally, half the length of the calyx, and placed in its concavity, (nectary, Linn. which he calls the lateral edge of the germ, dilated outwards.) *Pift.* germ roundifh, villous, fixed obliquely upon a fhort peduncle; ftyle upright, awl-fhaped; ftigma trifid. *Peric.* berry or drupe roundifh, a little compreffed, with one feed. *Seed* wrinkled, compreffed, hard. Poiret.

Eff. Ch. Flowers dioicous. Male. *Calyx* four-leaved. Corolla none. Stamens four, monadelphous, attached to a nectareous difc at the centre of the flower. Female. Calyx one-leafed. Stigmas three. Berry globular, with one feed.

Sp. C. *ciffampelos*, *pareira*, Linn. Sp. Pl. 1. Mart. 1. (Clematis baccifera, Sloan. Jam. i. 200. Plum. Amer. tab. 93. Convolvulus brafilianus, Rai Hift. 1331. Caapeba, Marcg. Braf. 24. Pic. Braf. 94. *β*. C. fcandens, Browne Jam. 357. Caapeba folio orbiculari umbilicato, et tomentofo, Plum. Gen. 33.) "Leaves peltate, heart-fhaped, emarginate, entire." Linn. 2. C. *caapeba*, Linn. Spec. 2. Mart. 2. (Caapeba folio orbiculari non umbilicato, Plum. Gen. 33. Ic. 6. fig. 2.) "Leaves petioled at the bafe, entire." Linn. We have followed Linnæus in keeping thefe two diftinct, efteeming the mode of the infertion of the petiole into the leaf a found fpecific character. Poiret, from a diligent comparifon of fpecimens in the herbariums of La Marck, Juflieu, and Commerfon, brought fome from the Weft, and others from the Eaft Indies, makes them one fpecies, which he calls C. *cocculus*, uniting with them under the fame trivial names, menifpermum cocculus of Linnæus and Gærtner, which produces the cocculus indicus of the fhops. See COCCULUS *indicus*. He gives the following defcription of thefe united fpecies, formed from the above-mentioned fpecimens. *Stems* woody, farmentous, cylindrical, climbing, and twining, a little ftriated, flightly villous. *Leaves* two or three inches broad, alternate, petioled, almoft orbicular, heart-fhaped, or fometimes entire at the bafe, obtufe, or flightly emarginate at their tip, mucronate, entire at the edges, green on the upper furface, cloathed underneath with more or lefs of a fhort whitifh down, foft to the touch; petioles from one to two inches long, villous, cylindrical, with a remarkable curvature near the bottom, inferted in many individuals into the leaves at a fmall diftance from the bafe, fo as to make them appear peltate or orbicular (C. pareira, Linn.), in others directly into their lower edge (C. caapeba, Linn.). Male flowers very fmall, panicled. *Panicles* lateral, fhort, peduncled, loofe, much branched, folitary or in pairs, fometimes by threes, and feldom more, fhorter than the petioles, and fituated a little above their axils; ramifications of the panicle villous, dichotomous, flender, almoft capillary, forming a kind of cyme, with very fmall, villous bractes. *Female flowers* in racemes, altogether different from the males in their mode of inflorefcence. *Racemes* elongated, narrow, foft, tomentous, pendulous, often longer than the petioles, and even than the leaves, axillary, from one to three in an axil. *Bractes* refembling the leaves, but fmaller, alternate, orbicular, mucronate, tomentous. *Flowers* very fmall, axillar, fafcicled. *Fruit* gibbous on one fide, flightly villous when young, fmooth afterwards, about the fize of a hazel nut. A native of the Eaft and Weft Indies. 3. C. *fmilacena*, Linn. Sp. 3. Mart. 3. (Smilax lenis, Catef. Car. 1. tab. 51.) "Leaves heart-fhaped, acute, angular." *Stems* flender, running up walls, and twining about pofts and trees. *Leaves* refembling thofe of common ivy. *Berries* about the fize of fmall peas, growing in clufters, red. Linnæus never faw the fructification complete. 4. C. *fruticofa*, Linn. jun. Supp. 432. Mart. 3. Thunb. "Stem erect, fhrubby; leaves egg-fhaped, petioled, entire." A native of the Cape of Good Hope. 5. C. *ovata*, Poir. 2. "Leaves egg-fhaped, obtufe, almoft entirely fmooth; racemes flender, elongated, pubefcent." *Stems* woody, cylindrical, flightly ftriated. *Branches* numerous, alternate, climbing, a little villous. *Leaves* about two inches long, from twelve to fifteen lines broad, alternate, petioled, mucronate, entire, firm, finely veined, green, fmooth, and a little fhining above, with a few fhort hairs along the nerves underneath; petioles about an inch long, flender, cylindrical, villous towards their upper extremity. *Flowers* fmall; racemes fimple, lateral, folitary or in pairs, fituated a little above the axils of the leaves; bractes villous, very narrow, almoft awl-fhaped, very fhort, alternate. *Fruit* a dry berry or drupe, kidney-fhaped, orbicular, fmooth, flightly compreffed at the fides, about the fize of a lentil. A native of the Eaft Indies; obferved by Sonnerat, who fent fpecimens to La Marck. 6. C. *laurifolia*, Lam. 3. "Leaves coriaceous, ovate-oblong, quite fmooth; fruit very large." *Stems* farmentous, fhrubby, fmooth, ftriated, yellowifh. *Branches* pendulous. *Leaves* alternate, petioled, quite entire at their edges, with a ftrong longitudinal nerve underneath, narrowed, and obtufe at their fummit, rounded at the bafe; petiole fhort, thick. *Flowers* of the female in fhort, axillary racemes. *Fruit* oval, much wrinkled, pulpy, dark brown when ripe. A native of America. Specimen fent to La Marck from the ifland of St. Thomas by Richards. 7. C. *capenfis*, Poir. 4. (C. apenfis, Linn. jun. ?) "Leaves ovate-acute, flightly obtufe, fmooth; petioles much fhorter than the leaf." *Stems* woody, greyifh. *Branches* flender, climbing. *Leaves* alternate, petioled, elongated into a weak point, mucronate, entire, green, reticulated, thickifh; petioles from two to four lines long. *Flowers* panicled, about the fize of a pin's head, nearly fpherical, clothed with a cottony down; panicles fmall, axillary, tomentous, whitifh, much branched, a little longer than the petioles. A native of the Cape of Good Hope. Specimen fent to La Marck by Bergius. 8. C. *humilis*, Poir. 5. "Leaves fomewhat heart-fhaped; the younger ones femi-orbicular; axils woolly; ftem low, fhrubby." *Stems* not more than from eight to ten inches high, flender, cylindrical, ftriated, branched. *Leaves* alternate, petioled, obtufe, mucronate, fmooth; petiole flender, fcarcely half the length of the leaves. *Flowers* whitifh, in fmall, tomentous, fafcicles. A native of the Cape of Good Hope; obferved by Sonnerat, who fent fpecimens to La Marck.

Poiret obferves, that though the fpecies of Ciffampelos are eafily diftinguifhed from thofe of menifpermum by the fructification, yet as both genera refemble each other in habit, and as the flowers of each are fo fmall that they cannot be eafily diffected in a dried fpecimen, it is poffible that fome fpecies of Menifpermum may have been referred to Ciffampelos, and *vice verfâ*.

CISSE, in *Ancient Geography*, a town of Africa, in Mauritania Cæfarienfis, according to Ptolemy. The Itinerary of Antonine calls it *Cifi*, and makes it a Municipium; about 12 miles from Rufucurrium. It was epifcopal.

CISSENE, a mountain of Thrace.

CISSIA, a country of Afia, whofe capital was Sufa, marked by Philoftratus at one journey from Babylon. Sufiana formed a part of Ciffia, and it is now called Chofiftan, or Khofiftan, which fee. The inhabitants were called Ciffii.

CISSII *Montes*, mountains of Afiatic Sarmatia, where was the fource of the river Imitys.

CISSINE, a town of Thrace, in the vicinity of the mountain *Ciffene*.

CISSINUS, a town of Afia in Perfia, mentioned by Æfchylus, and placed by Ortelius in the country called *Ciffia*.

CISSITES, in *Natural Hiftory*, a name given by the ancients to that fpecies of the flinty *ætites*, or eagle-ftone, which is covered with the common white coat of the flints. Pliny mentions it as found principally about Captos, and being externally of a white colour, and rattling when fhaken.

CISSOID, in *Geometry*, a curve of the fecond order, firft invented by Diocles; whence it is peculiarly called the ciffoid of Diocles.

The genefis of the ciffoid may be thus conceived: to the diameter A B (*Plate Analyfis, fig.* 1.) of the femicircle A O B, draw an indefinite line, at right angles, B C: then, draw the right line A H, and make $AM = IH$, or $HM = AI$; and in the other quadrant, $LC = AN$, or $CN = AL$. Thus will the points M and L be in a curve line, A M O L; which is the ciffoid of Diocles.

If the circle were completed, with the fame conftruction in the other femicircle, we fhould have another part of the curve A *m o l*. Sir Ifaac Newton refers this curve to the clafs of defective hyperbolas, being the 42d fpecies in his "Enumeratio Linearum tertii Ordinis." And in his appendix "De Equationum Conftructione Lineari," at the clofe of his "Arithmetica Univerfalis," he gives another elegant method of defcribing this curve, by the continual motion of a fquare ruler.

Properties of the CISSOID.—From the genefis it follows:

1. That the curve has two infinite legs, A M O L, A *m o l*, meeting in a cufp A, and tending continually towards the indefinite line C B D, which is their common afymptote.

2. That drawing the right lines P M and K I, perpendicular to A B; we fhall have $AP : KB :: AM : IH$. But $AM = IH$; confequently, $AP = KB$. And therefore $AK = PB$; and $PN = IK$.

3. After the fame manner, it appears that the ciffoid A M O bifects the femicircle A O B.

4. Again, $AK : KI :: KI : KB$ from the nature of the circle. That is, $AK : PN :: PN : AP$. And again, $AK : PN\ (KI) :: AP : PM$, by the property of fimilar triangles A K I, A P M; therefore, $PN : AP :: AP : PM$. Confequently, A K, P N, A P, and P M, are four lines in continual proportion. And if $PN = v$, $AP = x$, $PM = y$; $x^2 = vy$. And after the fame manner it may be fhewn, that A P, P N, A K, and K L, are in continual proportion. Or, if the diameter A B be $= a$, the abfcifs $AP = x$, and P M the ordinate $= y$, as before;

fore; we fhall have x (A P) : $a - x$ (P B) :: $y^2 : x^2$, or $x^3 = \overline{a - x} \times y^2$; which is the equation of the curve.

5. Hence, in the ciffoid, the cube of the abfcifs A P is equal to a folid arifing from the fquare of the femiordinate P M, multiplied into the complement of the diameter of the generating circle P B. Confequently, when the point P falls on B, then $x = a$, and B C $= y$; and $y^2 = \frac{a^3}{o}$. Wherefore, o : 1 :: $a^3 : y^2$; that is the value of y becomes infinite; and, therefore, the ciffoid A M O L, though it continually approach B C, will never meet it.

6. Whence it appears, that B C is an afymptote of the ciffoid.

7. The whole infinitely long ciffoidal fpace, contained betweeen the infinite afymptote B C D, and the curves L O A o l, &c. of the ciffoid, is equal to triple the generating circle A O B o A.

The ancients made ufe both of the conchoid and ciffoid, for the finding of two mean continual proportionals between two given right lines.

Sir Ifaac Newton, in his laft letter to M. Leibnitz, has fhewn how to find a right line equal to one of the legs of this curve, by means of the hyperbola; but the inveftigation which he there fuppreffed, may be found in his Fluxions. See more on this curve in Wallis's Works, vol. i. p. 545.

For the quadrature, fubnormal, and fubtangent of the ciffoid, fee QUADRATURE, SUBTANGENT, &c.

CISSOID *angle*. See ANGLE.

CISSUS, in *Botany*, Diofc. from Κισσος, ivy. Linn. Gen. 147. Schreb. 192. Juff. 267. Vent. 3. p. 168. Lam. Ill. 228. Achit. Lam. Encyc. Clafs and order, *tetrandria monogynia*. Nat. Ord. *Hederaceæ*, Linn. *Vites*, Juff.

Gen. Ch. *Cal.* Perianth one-leafed, fhort, almoft entire, or obfcurely four-toothed. *Cor.* Petals four, ovate-oblong, fomewhat concave, a little fpreading; nectary, a rim furrounding the germ. *Stam.* Filaments four, the length of the corolla, inferted into the nectary; anthers roundifh. *Pift.* Germ fuperior, roundifh, retufe; ftyle the length of the ftamens; ftigma fimple, acute. *Peric.* Berry round or didymous, retufe, fhining, furrounded at the bafe by the calyx. *Seeds,* one or two (rarely three or four), boney, roundifh, fomewhat angular.

Eff. Ch. Calyx nearly entire. Petals four. Berry one or two-feeded, furrounded at the bafe by the calyx.

* *Leaves fimple.*

1. C. *vitiginea*, Linn. 1. Mart. 1. Lam. Encyc. 1. Ill. 1612. Willd. 1. (Arbufcula baccifera; Pluk. Mart. 27. tab. 337. fig. 2.) "Leaves heart-fhaped, with about five lobes, tomentous," Linn. "Leaves heart-fhaped, repand-toothed, villous underneath," Lam. A fhrub, with the habit of a vine. *Stem* farmentous. *Branches* thinly covered with a fhort down. *Leaves* two inches long, alternate, petioled. *Flowers* in compound umbels, one oppofite to each leaf, longer than the petioles, very fmall, numerous, cottony on the outfide; peduncles of the univerfal and partial umbels, unequal in length. *Berries* bluifh, pear-fhaped, about the fize of a pea. A native of the Eaft Indies, introduced into England about 1772. 2. C. *tomentofa*, Lam. Ill. 1613. (C. capenfis, Willd. 2. Vitis capenfis, Thunb. 2.) "Leaves generally pentagonal, obtufely-toothed, clothed underneath with a ferruginous down." *Root* perennial. *Leaves* fomewhat truncated at the bafe. A native of the Ifle of Bourbon. 3. C. *angulata*, Lam. Ill. 1614. "Leaves generally pentagonal, angularly lobed, cornulate, tomentous underneath." A native of the Eaft Indies. 4. C. *rotundifolia*, Mart. 5. Lam. Ill. 1615. (Sælanthus rotundifolius, Forfk. Ægypt. tab. 4.) "Leaves cordate-roundifh, toothed, fmooth." *Flowers* numerous, in oppofite racemed umbels, about four on each common peduncle and fimple; peduncles nearly the length of the leaves. A native of Arabia. 5. C. *cordifolia*, Linn. Sp. Pl. 2. Mart. 4. Lam. Encyc. 2. Ill. 1616. Willd. 5. Burm. Amer. tab. 259. fig. 3. (Vitis, Plum. gen. 18. Icon. 269. fig. 3.) "Leaves heart-fhaped, quite entire," Linn. *Root* perennial. *Stems* farmentous, woody, clothed with a fhort down, efpecially the younger branches. *Leaves* terminated by a fhort point, almoft entire, flightly angular, fmooth above, a little cottony underneath, particularly on the nerves. *Flowers* in compound corymbs, oppofite to the leaves. *Berries* bluifh, fmall, almoft pear-fhaped, with a point at the fummit, one-feeded. A native of South America. 6. C. *ficyoides*, Linn. Sp. Pl. 3. Mart. 6. Lam. Ill. 1617. Pl. 84. fig. 1. Willd. 7. (C. latifolia β Lam. Encyc. 3. Vitis, Plum. Ic. 259. fig. 2. Bryonia; Sloan. Jam. 106. hift. tab. 144. fig. 1.) "Leaves egg-fhaped, naked, fetaceous-ferrated," Linn. "Leaves heart-fhaped, ferrated, fmooth and even on both fides, edged with mucronate teeth," Lam. *Root* perennial. *Stem* fomewhat woody, herbaceous at the top, climbing, branched, marked with red fpots. *Leaves* petioled, alternate, nerved, fomewhat fucculent. *Flowers* yellow; petals broader at the bafe, egg-fhaped, reflexed, deciduous; anthers orange. *Berry* oblong, black. A native of Jamaica, cultivated by Miller before 1768. The berries are fometimes eaten by the negroes and natives. 7. C. *latifolia*, Lam. Encyc. 3. Ill. 1618. Willd. 4. (Funis crepitans major; Rumph. Amb. 5. tab. 164. fig. 1. Schunambu Valli; Rheed. Mal. 7. tab. 11.) "Leaves cordate-ovate, villous, acuminate, fetaceous-ferrated; branches tetragonal." *Stems* woody, knotty, farmentous, climbing up the neighbouring trees. *Leaves* large, at leaft five inches broad, fometimes a little three-lobed; petioles near three inches long; tendrils large, oppofite to the leaves. *Flowers*, according to Rheede, fmall, whitifh; ftamens none; ftyle one. Hence La Marck conjectures this fpecies to be monoicous. *Berries* black, fmooth and fhining, fucculent. A native of woods in the Eaft Indies and ifland of Madagafcar. 8. C. *repanaa*, Willd. 3. Vahl. Symb. 3. p. 18. "Leaves heart-fhaped, entire, fometimes a little lobed, repand, fmooth on both fides." *Root* perennial. *Stem* cylindrical, zig-zag, jointed, tomentous when young, afterwards fmooth. *Leaves* petioled, fometimes terminated with a fhort obtufe point; ftipules egg-fhaped, membranous, acute, oppofite, deciduous. *Flowers* in a dichotomoufly branched umbel of three rays, oppofite to the leaves. *Berries* pear-fhaped, the fize of a pea, mucronate with the permanent ftyle. A native of the Eaft Indies. 9. C. *ovata*, Lam. Illuft. 1619. Brown. tab. 4. fig. 1, 2. "Leaves egg-fhaped, acuminate, fparingly toothed, fmooth and even on both fides." A native of Guadaloupe. 10. C. *canefcens*, Lam. Ill. 1620. "*Leaves* ovate-oblong, oblique, finely toothed, fomewhat tomentous, grayifh." Refembling the preceding in the form of its leaves. A native of Peru, obferved by Dombey. 11. C. *umbellata*, Mart. 15. Lour. Cochin. 84. "Leaves egg-fhaped, quite entire; flowers in umbels." *Stem* fhrubby, twining, long, branched. *Leaves* oppofite, fmooth. *Flowers* white, in compound terminal umbels; corolla bell-fhaped, woolly within; calyx truncated. A native of China about Canton. 12. C. *quadrangularis*, Linn. Mant. 39. Mart. 7. Lam. Encyc. 4. Ill. 1621. Willd. 8. (Funis quadrangularis, Rump. Amb. 5. tab. 44. fig. 2. Planta baccifera fcandens, Pluk. Phyt. 310. fig. 6. Sælanthus quadrangularis, Forfk. Defc. 33. Icon. tab. 2.) "Leaves toothed,

 flefhy,

fleshy, serrate-toothed; stem tetragonous, somewhat swell[illegible].” Linn. “Leaves somewhat deltoid, serrate-toothed, naked; stem tetragonous, jointed, fleshy.” Lam. *Root* perennial, tuberous. *Stem* very long, climbing, thickened, contracted, smooth and even, perennial. *Leaves* alternate, petioled, smooth on both sides, acutely and remotely serrated; petioles cylindrical; tendrils opposite to the leaves. A native of Arabia and the East Indies; found also by Loureiro near Mosambique in Africa. The inhabitants of Bengal, and of the coast of Coromandel, eat the branches stripped of their bark, and boiled or macerated in water.

* *Leaves compound.*

13. C. *acida*, Linn. Sp. Pl. 4. Mart. 8. Lam. Encyc. 5. Ill. 1622. Willd. 9. (Sicyos trifoliata, Linn Sp. Pl. ed. 1. Irsiola, Brown. Jam. 147. Bryonia, Sloan. Jam. 106. hist. 1. tab. 142. fig. 6. Bryonioides, Pluk. Alm. 71. tab. 152. fig. 2. Vitis, Plum. Sp. 18. tab. 259. fig. 5.) “Leaves ternate, inversely egg-shaped, smooth, fleshy.” Linn. *Stem* from three to five feet high, woody, and much [illegible], climbing; branches slender; tendrils simple. *Leaves* [illegible], of a fine green colour, small; leaflets oval-wedge-shaped. *Flowers* in umbels, small, herbaceous, L[illegible]. A native of Jamaica, in woods near the coast. The whole of the plant is acid. 14. C. *trifoliata*, Linn. Sp. Pl. 5. Mart. 9. Willd. 11. (C. alata, Lam. Enc. 5. Ill. 1623. Jacq. Amer. tab. 182. fig. 10. Irsiola triphylla scandens, Brown. Jam. 147. Bryonia, Sloan. Jam. 106. hist. 1. tab. 144. fig. 2.) “Leaves ternate, serrated; branches membranous-angular.” *Stem* somewhat shrubby, climbing, with five or six angles, rooting, branched, green; angles slightly winged. *Branches* herbaceous, lax. *Leaves* on long pentangular petioles; leaflets on short peduncles, egg-shaped, acute; the lateral ones oblique, serrated, nerved, smooth on both sides (tomentous underneath, Lam.) stipules at the base of the petioles roundish. *Flowers* in four-cleft umbels, blood red, small. *Berry* roundish, black, one-seeded. A native of Jamaica, where it climbs high above the branches of the trees upon the mountains. C. 15. C. *obtusifolia*, Lam. Encyc. 7. Ill. 1625. “Leaves ternate; leaflets inversely egg-shaped, obtuse, toothed, pubescent.” Nearly allied to the preceding, and perhaps only a variety. A native of the East Indies, observed by Sonnerat. 16. C. *cinerea*, Lam. Ill. 1624. “Leaves ternate; leaflets pubescent, toothed, lateral ones somewhat heart-shaped; petioles cylindrical. Perfectly distinct from the preceding. A native of the East Indies. Sonnerat. 17. C. *cirrhosa*, Willd. 10. (Vitis cirrhosa, Thunb.) “Leaves ternate, villous; leaflets egg-shaped, serrated.” A native of the Cape of Good Hope. 18. C. *carnosa*, Lam. Encyc. 11. Ill. 1626. Willd. 14. (Tsjori-valli, Rheed. Mal. 7. tab. 9.) “Leaves ternate, egg-shaped, obtuse, serrated, smooth; branches and petioles cylindrical.” Vahl. “Leaves ternate; leaflets ovate-acute, serrated, naked; root thick.” Lam. Whole plant smooth. *Branches* striated, cylindrical. *Leaves* petioled; leaflets petioled, fleshy; lateral ones smaller, an inch long; common petiole the length of the leaves. *Flowers* small, reddish brown, umbelled; universal umbel with three rays; partial one with dichotomous divaricating branches; general peduncle longer than the leaf. *Berries* blackish, a little flattened above, with three or four seeds. A native of the East Indies. 18. C. *microcarpa*, Willd. 12. (Vitis, Plum. Ic. tab. 259. fig. 4.) “Leaves ternate, oblong, serrated, smooth, membranous.” *Branches* angular, but winged with a decurrent membrane as in C. trifoliata. A native of the West Indies. 19. C. *crenata*, Mart. 10. Willd. 13. (Vitis trifolia, Linn. Sp. Pl. Folium caussonis, Rumph. Amb. 5. tab. 166. fig. 2.) “Leaves ternate; leaflets roundish, crenate.” *Branches*, petioles, younger leaves and peduncles villous. *Tendrils* opposite to the leaves, compound. *Leaves* petioled; leaflets petioled, an inch long; lateral ones smaller and narrower on one side; the crenatures remote and mucronate; stipules small, oblong, obtuse. *Flowers* in dichotomous cymes; peduncles longer than the leaf and opposite to it; calyx minute; petals arched; filaments shorter than the corolla. A native of the East Indies. 20 C. *obovata*, Mart. 12. Willd. 15. Vahl. Symb. 3. p. 19. “Leaves ternate; leaflets inversely egg-shaped, quite entire, smooth.” *Stem* climbing, smooth. *Tendrils* opposite to the leaves, and of the same length, bifid. *Leaves* petioled, alternate; leaflets mucronate, membranous; lateral ones smaller and sessile; middle one petioled, three times the size of the others. *Peduncles* axillary, solitary, longer than the leaves, smooth, trichotomous; branchlets three-flowered, flowers pedicelled. Vahl. A native of the island of St. Crux and other parts of the West Indies. 21. C. *digitata*, Lam. Ill. 1627. (Sælanthus digitatus, Forsk. Ægyp. tab. 3.) “Leaves fingered, egg-shaped, serrated; lower ones with five leaflets, upper ones with three.” A native of Arabia. 22. C. *pentaphylla*, Willd. 17. (Vitis pentaphylla, Thunb. Jap. 105.) “Leaves quinate; leaflets undivided, serrated.” *Stem* herbaceous, filiform, climbing, furrowed, smooth. *Leaves* alternate, petioled; leaflets egg-shaped, attenuated at the base, acuminate, thin, smooth; lateral ones less, about an inch long. *Flowers* very small, remote, in axillary racemes longer than the leaf; petioles two inches long. Thunb. A native of Japan. 23. C. *heptaphylla*, Mart. 14. Retz. Obs. 5. tab. 52. “Leaves with seven leaflets, serrated, hispid.” A sarmentous, climbing shrub. *Branches* pubescent. *Tendrils* opposite to the leaves, bifid. *Leaves* alternate, petioled; leaflets ovate-lanceolate, acuminate. *Flowers* small, panicled; panicles fastigiate, brachiate, peduncled, opposite to the leaves. Sent by Koenig from Calcutta. 24. C. *pedata*, Mart. 13. Lam. Enc. 10. Ill. 1628. Willd. 18. (Belutta-tsjori-villi, Reed. Mal. 7. tab. 10.) “Leaves pedate, with nine leaflets; leaflets ovate-lanceolate, somewhat toothed, pubescent underneath.” *Stems* cylindrical, villous. *Tendrils* opposite to the leaves, bifid. *Leaves* alternate, on petioles three inches long; leaflets from five to nine; leaflets petioled, green above, pubescent underneath, cottony on the nerves and petioles. *Flowers* in axillary dichotomous cymes, small, pubescent on the outside. *Berries* whitish, round, a little flattened at the top, ending in a small point. *Seeds* from one to four. A native of the East Indies. 25. C. *japonica*, Willd. 16. (Vitis japonica, Thunb. Jap. 104.) “Leaves pinnate, somewhat pedate, smooth; leaflets crenate, crenatures awned.” A native of Japan. 26. C. *orientalis*, Lam. Ill. 1629. Pl. 84. fig. 2. “Leaves somewhat bipinnate; leaflets egg-shaped, serrated; stem rather shrubby.” The habit of vitis arborea, but larger, the leaves less compound, and the leaflets larger. A native of the East. 27. C. *connivens*, Lam. Ill. 1630. “Leaves somewhat bipinnate; leaflets egg-shaped, rather obtuse, somewhat toothed; petals connivent.” Allied to the preceding, but distinct. Observed by Commerson in the island of Madagascar. 28. C. *mappia*, Lam. Ill. 1631. “Leaves somewhat bipinnate, smooth and even; leaflets egg-shaped, quite entire.” Observed by Commerson in the Isle of France.

Obs. The cissus arborea of Forskal is salvadora persica. Dryander in Linn. Trans. vol. ii. p. 220.

Cissus, in *Ancient Geography*, a mountain of Macedonia. —Also a town of Thrace. The town and mountain are situated,

tuated, according to Ortelius, toward the ſea, near Theſſalonica.

CISSUSA, a fountain of Greece in Bœotia, placed by Plutarch between the town of Thebes and that of Haliartes.

CISSYBIUM, in *Antiquity*, a drinking cup, moſt in uſe among country people. It was ſo called, either becauſe it was made of the wood of ivy, or was uſually crowned with its leaves.

CISTATOME, in *Surgery*, more properly written cyſtatome, from κυςις, *the bladder*, and τέμνω, *to cut*. See CYSTATOME.

CISTERCIANS, in *Eccleſiaſtical Hiſtory*, an order of religious reformed from the Benedictines, which formerly took its riſe from twenty-one zealous monks in the monaſtery of Moleſme, in Burgundy; who, with their abbot Robert, complaining that the rule of St. Benedict was not ſtrictly enough obſerved, obtained permiſſion of Hugh archbiſhop of Lyons, and legate of the holy ſee, to ſettle in a place called Ciſteaux, in the dioceſe of Chalons, five miles from Dijon.

In this retreat, which at that time was a miſerable deſert, covered with brambles and thorns, Eudes duke of Burgundy erected for them a houſe, into which they were admitted in 1098; endowing it with a conſiderable revenue. The biſhop of Chalons gave Robert the paſtoral ſtaff, in quality of abbot, and erected the new monaſtery into an abbey. This order made a moſt rapid and aſtoniſhing progreſs; it was propagated through the greateſt part of Europe in the following century, and was not only enriched with the moſt liberal and ſplendid donations, but alſo acquired the form and privileges of a ſpiritual republic, and exerciſed a ſort of dominion over all the monaſtic orders. In about 100 years after its firſt eſtabliſhment it boaſted of 1800 abbies, and was become ſo powerful, that it governed almoſt all Europe, both in ſpirituals and temporals. Within this period after their firſt riſe, the monks of this order were diſtinguiſhed by the patronage of St. Bernard, abbot of Clairval, whence they obtained the title of "Bernardin monks;" and, in the year 1132, they were exempted from the payment of tythes, and inveſted with other privileges and immunities by Innocent II. In 1152 this order had no fewer than 500 convents, all dedicated to the Bleſſed Virgin. They came into England in the year 1128, and had their firſt houſe at Waverley in Surry. Before their diſſolution they had eighty-five houſes here.

CISTERN, is properly uſed for a ſubterraneous reſervoir of rain-water.

The word, according to ſome, comes from *cis*, and *terram*; i. e. *in terram*; others derive it from *ciſta*, a *duct*, &c.

Earthen ciſterns muſt be made with good cement, to retain the water. And the bottom ſhould be covered with ſand to ſweeten and preſerve it.

Authors mention a ciſtern at Conſtantinople, the vaults whereof are ſupported by two rows of pillars, 212 in each row; each pillar being two feet in diameter. They are planted circularly, and in radii tending to that in the centre.

Anciently there were ciſterns all over the country in Paleſtine. There were ſome likewiſe in cities and private houſes. As the cities for the moſt part were built on mountains, and the rains fell regularly in Judea at two ſeaſons of the year only, in ſpring and autumn, people were obliged to keep water in ciſterns in the country, for the uſe of their cattle; and in cities for the conveniency of the inhabitants. There are ciſterns of very large dimenſions to be ſeen at this day in Paleſtine, ſome of which are a hundred and fifty paces long, and fifty-four wide. There is one to be ſeen at Ramah of two and thirty paces in length, and eight and twenty in width. Wells and ciſterns, fountains and ſprings, are generally confounded in the ſcripture language.

If the farmers of England would fall into the method uſed in Spain, and at Amſterdam, Venice, and other places, for ſaving the rain-water for the whole year, or at leaſt ſo much of it as would be neceſſary, in ciſterns, they would have always water for their cattle in the ſummer droughts, and many thouſand acres of land, now left uſeleſs, might be turned to profit.

The beſt way of preſerving the water for the ſervice of the houſe, is in ciſterns in the cellars. Theſe may be made with brick or ſtone, joined with plaiſter of Paris, which will keep out the wet very well; or with a kind of mortar made of ſlacked ſifted lime, with linſeed oil, and tow or cotton. A bed of good ſound clay may be laid at the bottom, and on this the bricks for the floor, and then the walls may be raiſed in the ſame manner, only leaving ſpaces behind them, into which clay is to be rammed in the like manner. Thus it will be a clay ciſtern, faced with brick; and the bricks will keep the clay moiſt, and prevent it from cracking, though it be not full of water. This will do in any ſhadowy place, as well as in cellars; and thus may a ciſtern be made in a garden, in ſome ſhadowy place, and covered over, which may receive the water running from the walks, and will retain it at hand, for the ſervice of the garden, all the year.

Where there is want of water for the cattle in the fields, the way is to dig a pond in ſome place into which there is a deſcent; then cover the bottom and ſides with a double coat of tough clay, each ſix inches thick, and each very well rammed; then to cover the bottom with large ſtones, which will keep the clay moiſt, and prevent its cracking, when not covered with water. But this is a troubleſome thing; for if there happen to be a crack in any part, it is often found neceſſary to go over the whole work again, before the pond will hold a drop of water.

Another method of making a pond hold water, is to daub it over with clay and mortar mixed together, and then with mortar alone. This has an advantage over the other way, becauſe if any crack happen, it may be mended by a cement of clean hair and tallow, mixed with ſlacked lime and the yolks of eggs, well beat together. This applied to the crack, will cloſe it ſafely, without neceſſity of undoing the whole work, as in the other caſe.

In chalky countries it is common to find a low place on the downs, and, digging a hole by way of a pit there, they cover the bottom evenly with the chalk rubbiſh, and when it is wetted by the rain, they ram it well, and afterwards drive cattle into it, and fold ſheep in it; the conſequence of all ſuch trampling is, that the bottom at length becomes ſo firm, that it holds the water perfectly well. By one or other of theſe means, ciſterns or reſervoirs may be made in every part of the country; and our farmers, if they would carefully try one or the other of them, as their land moſt required, would not have ſo much to complain of from droughts.

Ciſterns are often of the greateſt advantage in a place of war, by holding large quantities of rain-water for the uſe of the garriſon and inhabitants, when their wells or fountains fail through the drought, or the courſes of their ordinary ſupplies of water are diverted by an enemy.

CISTERN-*lock*, the ſame with chamber or pound-lock, a modern contrivance for raiſing or letting down boats from one canal to another, on a different level. See CANAL and LOCK.

CISTERNA, in *Geography*, a town of Piedmont; 12 miles E.S.E. of Turin.

CISTERNA,

[illegible], a town of Naples, in the province of [illegible] S. E. of Monte Angelo.

[illegible], a town of Naples, in the province of [illegible] S.E. of Monopoli.

Cisthena, in *Ancient Geography*, a town of Asia situated in the Adramyttian gulf, in Mysia, according to Pliny. Strabo speaks of it as a town that had been abandoned though it had a port, and he places it out of the gulf on the promontory of Pyrrha. Mela, as well as Pliny, places it in the gulf.

CISTHENE, a small island of Asia Minor, with a town of the same name, situated on the coast of Lycia, according to Strabo and Isocrates.

Cist-*Hepatic*. See Cyst-*Hepatic*.

Cisti, in *Botany*, (Cistoidæ; Vent.) one of the natural orders of Jussieu, with the following characters: *Calyx* five-parted. *Petals* five. *Stamens* numerous. *Germ* simple. *Style* one. *Stigma* one. *Capsule* many-seeded, either one-celled and three valved, or many-celled and many-valved; valves bearing the seeds in the middle; receptacle either septiform separating the cells, or linear and not prominent. *Seeds* numerous, small. *Stem* shrubby, or somewhat shrubby, or herbaceous. *Leaves* generally opposite, with or without stipules. *Flowers*, in spikes or umbellar corymbs. *Perisperm* fleshy. *Embryo* spiral, or else the radicle simply curved upon the lobes. He includes under it the following genera; *Cistus*, *Helianthemum*, both belonging to the cistus of Linnæus, *Viola*, *Pirequeta*, *Piparea*, and *Tachibota*, but observes that the last four are only allied to the cisti, differing from them in having a determinate number of stamens.

Ventenat has also the first three species, omitting, as usual, the genera taken up by Jussieu, with their barbarous names, and not very decided generic characters; but observes that they and Viola will probably form a new natural order, intermediate between the cisti and rutaceæ, differing from the former, and approaching some species of the latter in the determined number of their stamens, their sometimes three-celled fruit, and their uncurved embryo.

CISTIS. See Cystis, and Hypo-cistis.

CISTOCELE. See Cystocele.

CISTOIDES, in *Botany*. See Maternia.

CISTOPHORA, ancient silver coins, concerning the origin and date of which antiquarians have been much divided in opinion. M. Leblond, in a late "History of Ephesus," has assigned these circumstances with a great degree of probability. Among these coins which were struck in six towns of Asia, those of Ephesus are distinguished by numeral letters on the face, which are dates of years; these were struck upon the arrival of every new Roman proconsul in Asia; and this was a right peculiar to the Ephesians, on which they highly valued themselves.

CISTOTOMY. See Cystotomy.

CISTIC. See Cystic.

CISTRUM. See Sistrum.

CISTULA Catoptric. See Catoptric.

CISTUS, in *Botany*, (Κιστος, Gr.; derivation uncertain), Linn. Gen. 673. Schreb. 913. Gært. 483. Jussieu, 294. Tourn. cl. 6. s. 4. gen. 10. Helianthemum, Tourn. Juss. 294. Gært. 484. Vent. vol. iii. p. 220. Class and order, *polyandria monogynia*. Nat. ord. *Rutaceæ*, Linn. *Cisti*, Juss.

Gen. Ch. *Cal.* either three or five-leaved; leaves roundish, concave. *Cor.* Petals five, roundish, flat, spreading. *Stam.* Filaments numerous, capillary, shorter than the corolla; anthers roundish, small. *Pist.* Germ superior, roundish; style simple, the length of the stamens; stigma flat, orbiculate. *Peric.* Capsule roundish, surrounded by the calyx; three, five or ten-valved; one, three, five, or ten-celled. *Seeds* small, numerous.

Eff. Ch. Calyx three or five-leaved; leaves unequal. Capsule superior, angular, many-seeded.

Obs. The cistus and helianthemum of Tournefort, Jussieu, Ventenat, and Gærtner, certainly form one natural genus, as Linnæus has made them; but they may advantageously be separated in two grand divisions, as La Marck has distributed them. The cistus of Tournefort, &c. has a many-celled capsule, with as many valves as there are cells, and seeds affixed to the axis, and a spiral embryo. These are either shrubs or undershrubs; the leaves opposite and without stipules; flowers in umbels, with very unequal calyx-leaves, either purple or white, commonly large and specious. Helianthemum has a one-celled, three-valved capsule, with seeds fixed to the valves, and a curved embryo. They are shrubs, undershrubs, or herbaceous, their leaves opposite or rarely alternate, either with or without stipules; their flowers in terminal spikes or racemes, most frequently yellow, smaller than those of Tournefort's cistus, but very deciduous in both.

* *Cisti*, Tournefort.

Without stipules.

Capsule five or ten celled, with the same number of valves.

1. C. *capensis*, Linn. Sp. Pl. 1. Mart. 1. Willd. 1. Vahl. Sym. 3. p. 68. "Arborescent; leaves ovate-lanceolate, petioled, three-nerved, finely toothed, naked on both sides." *Branches* cylindrical, with a few scattered hairs, purplish. *Leaves* three inches long, remote, ciliated with long hairs; upper ones sessile, not connate at the base; lower ones attenuated at the base into a very short petiole, acute, with about three nerves, which become evanescent towards the middle of the leaf. *Flowers* yellow; peduncles terminal, trifid; partial ones three-flowered; calyx-leaves heart-shaped, acuminate, hairy, finely toothed, ciliated, very hairy when young. Vahl. A native of the Cape of Good Hope. La Marck has not taken up this species, and Ventenat doubts whether its existence has been sufficiently ascertained; but Vahl's description here given will, we presume, establish its right to "a local habitation and a name." It is distinguished by its leaves being finely toothed. 2. C. *villosus*, Mart. 2. Lam. 1. Willd. 2. (C. pilosus, Linn. Sp. Pl. 2. C. mas folio rotundo hirsutissimo, Bauh. Pin. 464. Tourn. 259.) "Arborescent; leaves egg-shaped, petioled, hairy." Linn. *Stem* woody, much branched, forming a large, bushy head, three or four feet high. *Branches* cylindrical; the smaller ones villous, a little cottony and whitish. *Leaves* slightly wrinkled, of a cinereous green colour above and underneath, narrowed into a petiole towards their base. *Flowers* of a fine red colour, near an inch and half in diameter; peduncles an inch long or more, one-flowered. A native of Spain and Italy. 3. C. *creticus*, Linn. 9. Mart. 9. Lam. 2. Willd. 13. (C. ledon cretense, Bauh. Pin. 467, but not all the synonyms. C. ladanifera cretica, Tourn. Cor. 19.) "Arborescent; leaves spatulate-ovate, petioled, nerveless, scabrous; calyx-leaves lanceolate." Linn. "Shrubby; leaves spatulate-ovate, petioled, wrinkled, hairy, undulated at the edges; peduncles short, one-flowered; calyx-leaves mucronate, villous." Lam. *Root* hard, woody, white within, reddish without, with long hairy fibres. *Stems* commonly several, a foot and half high or more, sometimes an inch thick, brown or greyish, cracked. *Branches* reddish-brown; young shoots villous, whitish-green. *Leaves* deep green, opposite, thickish, narrowed into a petiole at their base, an inch or more long, eight or nine lines long; petioles three or four lines long, very villous. *Flowers* rose-purple,

purple, with a yellow claw, terminal, on short peduncles; calyx five-leaved; petals five, roundish, thin, rumpled. *Capsule* egg shaped, obtuse, about five lines long, hard, brown, surrounded with the leaves of the calyx, five-celled. *Seeds* red, angular. A native of the Levant; found by Tournefort in the isle of Candy or Crete. It is from this shrub that the officinal drug, ladanum, or, as it is sometimes spelt, labdanum, is obtained; a resinous substance secreted from the leaves and branches of the plant. Three sorts have been described by authors, but only two are now to be met with in the shops. The best and rarest is in dark-coloured masses, of the consistence of a soft plaster, and growing still softer on being handled. The other is in long rolls, coiled up, much harder than the preceding and less dark. The soft kind has an agreeable smell, and a lightly pungent bitterish taste; the hard is much weaker, owing to its having a larger admixture of fine sand, which in that examined by the French Academy amounted to three-fourths of the mass. But independently of designed adulterations, it can scarcely be collected pure; the dust blown from the loose sands among which it grows, being retained by the tenacious juice. It was formerly employed internally as a pectoral and astringent in catarrhal affections, dysenteries, and several other diseases. In England it is now wholly confined to external use. It is an ingredient in the stomachic plaster, or emplastrum ladani, of the London Pharm. It is also used in the way of fumigation, on account of its pleasant smell. Woodvil. Med. Bot. vol. ii. p. 249. Tournefort saw seven or eight country fellows in their shirts and drawers, and in the hottest part of the day, drawing over the plant a kind of whip composed of numerous long leathern thongs, and collecting the resin, which is afterwards scraped clean off with a knife, and made up into cakes of different sizes for sale. In the time of Dioscorides it was carefully detached from the beards and thighs of goats who had broused upon the shrub. 4. C. *purpureus*, Lam. 3. "Shrubby; leaves lanceolate, acute at both ends, wrinkled; peduncles short, one-flowered." A shrub four feet high or more. *Branches* numerous, a little villous, straight, and rather upright. *Leaves* two inches long or more, about half an inch broad, a little undulated at the edges. *Flowers* red, large, terminal; petals with a brownish purple spot at their base; calyx-leaves five, egg-shaped, mucronate, a little villous. Cultivated at Paris by Cels, and supposed to have been brought from the Levant. 5. C. *parviflorus*, Lam. Enc. 4. Willd 14. (C. mas creticus, breviori folio, parvo flore, Tourn. Cor. 19.) "Shrubby; leaves petioled, egg-shaped, acute, tomentous, peduncles villous, generally one-flowered." *Root* an inch thick, hard, divided into many long and thick fibres. *Stems* several, woody, branched. *Leaves* opposite, of a cinereous-green colour, reticulated underneath with nerves, and generally channelled. *Flowers* only an inch broad, rose-coloured: petals somewhat heart-shaped, yellowish at the base; calyx-leaves five, mucronate, villous on the back. Found by Tournefort in the isle of Candy. 6. C. *complicatus*, Lam. Enc. 5. (C. folio rotundiore, incano, quasi complicato, Tourn. Cor. 19.) "Shrubby; leaves petioled, egg-shaped, tomentous, almost donbled together; peduncles short, many-flowered." A small tufted shrub, without branches near the base. *Leaves* small, reticulated underneath, bent, growing almost double, so as to form a deep channel. *Flowers* red; common peduncles from the forks of the upper branches short, bearing three or four pedicelled flowers. *Capsules* very small, egg-shaped, brown, not angular. A native of the Levant. 7. C. *incanus*, Linn. 7. Mart. 8. Lam. 6. Willd. 12. Bot. Mag. 43. (C. mas angustifolius, Bauh. Pin. 464. C. mas secundus, Clus. Hist. 1. p. 69. Lob. Ic. ii. p. 111. C. mas 2 folio longiore, Tourn. 259.) "Arborescent; leaves spatulate, tomentous, wrinkled; lower ones sheathing the base, connate." Linn. *Stem* two feet high. *Branches* villous, whitish towards the summit. *Leaves* opposite, sessile, oblong, a little cottony on both sides, with three nerves at the base. *Flowers* purple, on simple peduncles; petals heart-shaped. A native of Spain and the south of France. 8. C. *breviorifolius*, Mart. 52. (C. mas folio breviore, Bauh. Pin. 464. C. mas 3. Clus. Hist. 69.) "Shrubby; leaves ovate-lanceolate, connate, hirsute, wrinkled; peduncles longer." *Stem* three or four feet high. *Leaves* shorter and greener than those of C. villosus and incanus. *Flowers* deep purple, small. A native of Portugal. 9. C. *lusitanicus*, Mart. 53. (C. mas lusit. fol. amplissimo incano, Tourn. Inst. 259.) "Shrubby; leaves egg-shaped, obtuse, villous, nerved, and wrinkled underneath; flowers larger." *Branches* white and hairy. *Leaves* larger and rounder than those of the preceding species, even on their upper side, rough, and full of veins underneath. *Flowers* light purple, very large. A native of Portugal. 10. C. *hispanicus*, Mart. 54. "Shrubby, villous; leaves lanceolate, green, connate; flowers sessile; calyxes acute." *Stem* not so high as in either of the three preceding species, branched near the root; branches hairy, erect, with three or four terminal flowers, sitting close, without peduncles. At each joint of the stem there is a slender branch, having three pairs of small leaves, of the same shape with the others, and terminated by a single flower. *Flowers* deep purple. A native of Spain. 11. C. *heterophyllus*, Willd. 11. Desfont. Fl. Atl. i. p. 411. tab. 11. "Leaves ovate lanceolate, sheathed at the base, revolute at the edges; calyxes and peduncles hirsute; peduncles generally one-flowered." *Stem* two feet high, much branched. *Younger branches* cylindrical, villous, hoary. *Leaves* opposite, smooth, and rather even on their upper surface, paler underneath, nerved; nerves beset with very short hairs, on short connate petioles. *Flowers* rose-coloured, large, terminal, one, two, three, or four, peduncled; peduncles with two small leaves proceeding from a little knot about their middle; calyx five leaved; leaves nearly equal, two inner ones acute. *Capsule* roundish, villous, five-celled. The same plant has frequently its lower leaves roundish, and its upper one lanceolate, whence the trivial name. Nearly allied to C. *incanus*. A native of uncultivated hills about Algiers. 12. C. *crispus*, Linn. Sp. Pl. 11. Mart. 11. Lam. 7. Willd. 18. (C. mas foliis chamedrys, Bauh. Pin. 464. C. mas 5. Clus. Hist. i. p. 69. C. mas foliis undulatis & crispis, Tourn. Inst. 259.) "Arborescent; leaves lanceolate, pubescent, three-nerved, undulated." Linn. A small shrub. *Stems* several, a foot and a half high, branched, a little decumbent at the base. *Branches* a little cottony or woolly, with many loose hairs. *Leaves* small, sessile, wrink'ed, whitish on both sides. *Flowers* purple, nearly sessile, three or four together at the summit of each branch, forming a head enveloped with floral leaves; calyx-leaves lanceolate. A native of Portugal. 13. C. *albidus*, Linn. 8. Mart. 10. Lam. 8. Willd. 15. (C. mas, folio oblongo incano, Bauh. Pin. 464. Tourn. Inst. 259. C. mas 1, Clus. Hist. i. p. 68.) "Arborescent; leaves ovate-lanceolate, tomentous, hoary, sessile, slightly three-nerved." Linn. *Stem* three or four feet high. *Branches* tomentous, not hairy. *Leaves* opposite, flat. *Flowers* purple, or rose-coloured, large, spacious; peduncles scarcely an inch long, terminal, cottony, one-flowered; petals not emarginate; calyxes cottony. A native of Spain and the south of France. 14. C. *sericeus*, Mart. 60. Willd 16. Vahl. Symb. i. p. 37. (C. latifolius magno flore, Barrel. Ic. 1315.) "Arborescent; leaves egg-shaped, tomentous, three-nerved; lower ones petioled; upper ones sessile;

fessile; peduncles hairy." *Stem* two or three feet high. *Branches* cylindrical, densely tomentous, hoary-white. *Leaves* very soft, obtuse, flat. *Flowers* purple, with a yellow spot in the middle; peduncle terminal, solitary, erect, beset with long purplish hairs; pedicels spreading towards the summit; lower ones three-flowered; upper ones one-flowered; calyx cloathed with soft silky hairs; inner leaves of the calyx three, egg-shaped, quite smooth on the inside; outer ones lanceolate; filaments purple; anthers yellow. 15. C. *hybridus*, Mart. 61. Willd. 17. Vahl. Symb. 1. p. 57. "Arborescent; leaves egg-shaped, petioled, hoary; branches scaly; peduncles elongated, hairy." *Stem* two or three feet high. *Branches* cylindrical, angular near the tip, hoary, covered with yellowish scales. *Leaves* half an inch long, nerved, easily broken. *Flowers* purple, in a terminal raceme; outer calyx-leaves caducous; germ villous. A native of Spain. 16. C. *vaginatus*, Mart. 57. Willd. 5. Hort. Kew. ii. p. 232. Jacq. Hort. Schoenb. iii. p. 17. tab. 282. (C. symphytifolius, Lam. 9.) "Shrubby; leaves petioled, oblong-lanceolate, villous on the upper surface; petioles sheathing at the base, connate." Lam. "Arborescent; leaves oblong, hairy, reticularly wrinkled underneath; petioles united at the base, sheathing, furrowed." Hort. Kew. *Stem* five or six feet high. *Branches* rough, reddish, grey, villous, white and almost cottony near the top. *Leaves* opposite, four or five inches long, nearly two broad. *Flowers* reddish, large, terminal; stamens yellow. A native of Africa. 17. C. *cordifolius*, Mart. 55. "Shrubby, leaves oblong, heart-shaped, smooth, petioles longer." *Stem* four or five feet high. *Branches* woody, slender, with a smooth brown bark. *Flowers* white, terminal, on long peduncles, cultivated by Miller. 18. C. *fasciculatus*, Mart. 56. "Leaves in bundles." *Stem* about nine inches high. *Leaves* narrow and fine, growing in clusters. *Flowers* pale straw-coloured, lateral and terminal, on slender peduncle; petals falling off in about two hours after opening. A native of the Cape of Good Hope; sent to Miller from Holland by Dr. Adrian-Van Royen. 19. C. *salvifolius*. Linn. Sp. Pl. 10. Mart. 7. Lam. 10. Willd. 10. C. femina, folio salviæ; Bauh. Pin. 464. C. femina; Clus. Hist. i. p. 70. Jacq. Collect. 2. p. 120. tab. 8. Hall. Helv. 1031. "Arborescent; leaves egg-shaped, petioled, hairy on both sides." Linn. "Shrubby; leaves petioled, egg-shaped, wrinkled, somewhat hairy; peduncles long, one-flowered." Linn. *Stem* from one and a half to three feet high, much branched, in some varieties procumbent. *Leaves* opposite, obtuse, greenish on the upper surface, with abundance of very short hairs, whitish, green, and almost cottony underneath. *Flowers* white, sometimes pale yellow. *Capsules* egg-shaped, pentagonal, five-celled, surrounded by the calyx. A native of Italy, Switzerland, the south of France, and Spain. There is a variety mentioned by La Marck, C. Cobariensis of Pourret, with leaves almost heart-shaped, acute, less villous, much wrinkled, and viscous, which may be the C. cordifolius, n. 17. Cultivated by Miller, and inserted in his dictionary, without any indication of its native country. 20. C. *populifolius*. Linn. Sp. Pl. 3. Mart. 3. Lam. 11. Willd. 3. C. ledon foliis populi nigræ major et minor; Bauh. Pin. 467. Tourn. 260. Ledon latifolium majus et minus; Clus. Hist. i. p. 78. Lob. Ic. ii. p. 121.) "Arborescent; leaves heart-shaped, even-surfaced, acuminate, petioled." Linn. "Shrubby; leaves petioled, heart-shaped, acute, veined underneath; peduncles bracteated, many-flowered." Lam. *Stem* three or four feet high, branched, with a brown even bark. *Branches* brittle; younger ones, petioles and peduncles beset abundantly with loose hairs. *Leaves* opposite, ciliated when young. *Flowers* white, large; peduncles axillary, with three or four pairs of oblong bractes; petals not spotted, but slightly stained with purple at their edges; calyxes trigonous before the flowers open; calyx-leaves five, almost heart-shaped, acute, the two inner ones coloured and transparent, Lam. A native of Portugal. 21. C. *longifolius*, Lam. 12. "Shrubby; leaves nearly sessile, ovate-lanceolate, villous and undulated at the edges, veined underneath; peduncles many-flowered." *Branches* reddish brown; small ones rendered harsh to the touch by loose hairs. *Leaves* opposite, acute at both ends, greenish on both sides; lower ones on very short petioles. *Flowers* white; axillary, from two to five-flowered; calyx-leaves slightly villous, a little heart-shaped, acute. Nearly allied to the preceding, but the leaves are almost sessile, and not at all heart-shaped. A native of Spain. 22. C. *laurifolius*, Linn. 4. Mart. 4. Lam. 13. Willd. 4. (C. ledon, foliis laurinis, Bauh. Pin. 467. Tourn. 360. Ledon. 1. Clus. Hist. 1. p. 77.) "Arborescent; leaves oblong egg-shaped, petioled, three-nerved, smooth on the upper surface; petioles connate at the base," Linn. "Leaves ovate-lanceolate, petioled, three-nerved, smooth above, tomentous underneath; petioles connate at the base; peduncles naked, many-flowered," Lam. A shrub five or six feet high. *Branches* brown, smaller ones beset with fine close-pressed hairs, not erect or loose, as in the preceding species. *Leaves* opposite; petioles villous, sheathing. *Flowers* white, upper ones forming an umbel; calyx-leaves three, egg-shaped, mucronate, concave on the inside, pubescent on the out. A native of Spain. Ladanum may be procured from it. 23. C. *cyprius*, Lam. 14. (Ledon. 3. cyprium; Clus. Hist. 1. p. 78.) "Shrubby, leaves petioled, lanceolate, smooth above, tomentous, hoary underneath; peduncles naked, with about three flowers; flowers spotted." An intermediate species between the preceding and following, differing from the former in its narrow leaves, and from the latter in its three or four-flowered peduncles. A shrub three or four feet high, with a brown bark, emitting in warm weather from its young branches, its petioles and the upper surface of its branches, a viscous humour like that of the next species, but rather less abundant. *Leaves* opposite, three-nerved underneath. *Flowers* white, peduncles solitary, three inches long; petals with a violet spot near the claw. *Capsules* somewhat egg-shaped, five-celled. A native of the isle of Cyprus, where ladanum is collected from it. 24. C. *ladaniferus*. Linn. 5. Mart. 5. Lam. 15. Willd. 7. Bot. Mag. tab. 112. (C. ladanifera hispanica, Ileis folio, flore candido.) "Arborescent; leaves lanceolate, even on the upper surface; petioles united at the base, sheathing;" Linn. "Shrubby; leaves nearly sessile, connate, lanceolate-linear, smooth above; tomentous underneath; peduncles bracteated, one-flowered; capsules ten-celled." Lam. *Stem* four or five feet high, branched. *Leaves* three inches long, about half an inch broad. *Flowers* very large, two or three inches in diameter, white, lateral, peduncles simple, furnished with bractes their whole length; bractes forming at their base a loose sheath, caducous; stigma sessile. *Capsules* ten-celled, ten-valved. There is a variety with a purple or violet spot in the centre of the flower. Willdenow makes C. undulatus and C. planus of Hortus Kewensis varieties of this species. The former has undulate, the latter flat leaves. A native of Spain. As this is not the plant by which the officinal ladanum is produced, the trivial name is not strictly proper; but as it has obtained the sanction of general usage, it is better to retain it, than to hazard the confusion which must arise from changing every specific name which is not so appropriate as might be wished: care should be taken to distinguish ladanum from laudanum, a well known invaluable medicine from papaver somniferum. 25. C. *ledon*, Lam. 16. Willd.

Willd. 6. (C. ladanifera monfpelienfium. Bauh. Pin. 467.) "Shrubby; leaves nearly feffile, lanceolate, nerved, connate, fmooth on the upper furface; flowers in corymbs, erect; peduncles and calyxes cloathed with filky hairs." A low fhrub from one to two feet high. *Leaves* oppofite, a little fhining, dark green above, pale or whitifh underneath. *Flowers* white, with a yellowifh tint at their centre, of a moderate fize, from three to five on each peduncle. A native of the fouth of France about Narbonne. It exudes a vifcous matter in tolerable abundance, and, according to La Marck, is the true ladaniferus of Montpelier, though not the monfpelienfis of Linnæus. 26. C. *hirfutus*, Lam. 17. (C. laxus, Hort. Kew. ii. p. 233. Willd. 9. C. ledon hirfutum, Bauh. Pin. 467. Tourn. 260. Ledon 4. Cluf. Hift. i. p. 78.) "Shrubby; leaves feffile, oblong, obtufe, hirfute; peduncles many-flowered; capfules fmall, covered by the large pyramidal calyx." A fhrub. *Stem* a foot and a half high. *Branches* numerous, flexible, villous, whitifh. *Leaves* oppofite, dark green, foft. *Flowers* white; peduncles befet with ftrong hairs; capfules egg-fhaped, fmooth, five-valved, five-celled. A native of Spain. We have preferred La Marck's trivial name on account of its correfpondence with the fynonyms of C. Bauhin and Tournefort. 27. C. *florentinus*, Lam. 18. (C. ladanifera florentina, Michael. Sherard.) "Shrubby; leaves narrow, lanceolate, wrinkled, reticulated underneath, nearly feffile; peduncles villous, about three-flowered." *Branches* brown, fmooth towards the bottom, pubefcent near the top. *Leaves* an inch and half long, oppofite, a little cottony underneath, not three-nerved. *Flowers* white; peduncles and calyxes befet with white, very fine, almoft filky hairs. Suppofed to be a native of Italy, defcribed by La Marck from a fpecimen in the herbarium of Juffieu. 28. C. *monfpelienfis*, Linn. Sp. Pl. 6. Mart. 6. Lam. 19. Willd. 8. Gært. tab. 76. fig. 10. (C. ledon foliis oleæ, fed anguftioribus, Bauh. Pin. 467. Tourn. 260. Ledon. 5. Cluf. Hift. i. p. 79.) "Shrubby; leaves linear-lanceolate, feffile, villous on both fides, three-nerved; peduncles branched, nearly unilateral." Lam. *Stem* about three feet high, branched. *Leaves* dark green, vifcous. *Flowers* white; peduncles villous. A native of the fouth of France. 29. C. *libanotis*, Linn. Sp. Pl. 13. Mart. 13. Lam. 20. Willd. 22. "Arborefcent; leaves linear, revolute; flowers umbelled." Linn. "Shrubby; leaves linear, revolute at the edges; flowers fomewhat umbelled; calyx three-leaved." Lam. α. "leaves green on both fides." C. ledon foliis anguftis, Bauh. Pin. 467. Tourn. 260. Ledon 6 and 9. Cluf. β. "Leaves canefcent; flowers fomewhat capitate." Ledon 7. Cluf. γ. Leaves hoary underneath." Ledon. 8. Cluf. *Stem* about two feet high. *Branches* cinereous; young ones cottony and whitifh near the top. *Leaves* feffile, narrow, revolute like thofe of rofemary. *Flowers* white or cream-coloured, fmall. *Capfules* fmall, five-celled, five-valved. A native of Spain.

* * *Helianthema*, Tourn.

Capfule three-valved, one or three-celled.

† *Without ftipules.*

(1.) *Stem woody.*

30. C. *umbellatus*, Linn. Sp. Pl. 14. Mart. 14. Lam. 21. Willd. 23. "Somewhat fhrubby, procumbent; leaves oppofite, linear; flowers umbelled." Linn. "Somewhat fhrubby; leaves oppofite, linear, revolute at the edges; flowers at the top of the peduncle umbelled." Lam. α. "leaves hoary underneath; ftem procumbent." β. "Leaves greenifh on both fides; ftem erect. (C. ledon, foliis thymi, Bauh. Pin. 467. Helianthemum foliis thymi, floribus umbellatus, Tourn. 250. Ledon 10. Cluf.) *Stem* fcarcely a foot high. *Flowers* white, numerous, partly lateral on the peduncle, partly terminal in a kind of umbel; calyx three-leaved. The *branches* of var. α. are procumbent, flender, regular, whitifh; its *leaves* rolled back at the edges like thofe of C. libanotis, white underneath, green above, a little ciliated at the edges. The ftems of var. β. are erect; its leaves not white underneath, narrower, the edges more rolled back, and fcarcely ciliated when completely open. A native of Spain and the fouth of France. 31. C. *ocymoides*, Mart. 66. Lam. 22. Will. 30. Vahl Symb. 3. p. 68. (C. folio fampfuci incanos, Bauh. Pin. 465. Cluf. Hift. i. p. 72. Lob. Ic. ii. p. 114. Helianthemum folio fampfuci, Tourn. 250.) "Leaves inverfely egg-fhaped, three-nerved; thofe of the fmall branches hoary on both fides, reflexed at the tip; flowers in racemes; peduncles and calyxes quite fmooth." Vahl. "Somewhat fhrubby; leaves petioled, keeled, hoary, very fmall; peduncles branched, umbel panicled." Lam. *Stem* about a foot high. *Branches* flender, cinereous. *Leaves* numerous, oppofite. *Flowers* white, with a dark purple fpot in the centre; peduncles long, flender. There is a variety in which the leaves are whiter, and the branches abundantly cloathed with rather long loofe hairs. C. fampfucifolius. Cav. Ic. tab. 366. A native of Spain. 32. C. *halimifolius*, Linn. Sp. Pl. 12. Mart. 12. Lam. 23. Willd. 20. "Two of the calyx leaves linear." Linn. "Shrubby; oblong-ovate; fomewhat acute, leffening into the peticle, hoary on both fides; peduncles long, branched, fomewhat panicled." Lam. *Stem* two or three feet high, much branched. *Branches* forming a regular head. *Leaves* larger than thofe of the preceding fpecies, but not more than feven or eight lines long, and three or four lines broad, oppofite. *Flowers* yellow, with a purple fpot in the centre. There is a variety in which the leaves are obtufe and almoft rounded at the tip. A native of Italy and Spain. 33. C. *algarvenfis*, Bot. Mag. 627. (C. lafianthus, Lam. 26. Helianthemum algarvienfe, Tourn. Inf. 250.) Arborefcent; ftem afcending; leaves hoary, ovate-lanceolate; peduncles fomewhat panicled; calyxes three-leaved, acute, hirfute" Bot. Mag. "Somewhat fhrubby; leaves oblong-obovate, keeled, tomentous, peduncles fhort, about one-flowered; calyxes very hirfute." Lam. *Stems* a foot and half high, much branched. *Branches* darkifh grey, cottony towards the fummit. *Leaves* rather fmall, oppofite, almoft feffile, obtufe, cottony on both fides, without being white but only grey. *Flowers* yellow, with a purple fpot in the centre, terminating the fmall lateral branches, remarkable for the long hairs with which the outfide of the petals is abundantly cloathed. Lam. Calyx-leaves three, equal, acute. Bot. Mag. We have no doubt with regard to the algarvenfis of Bot. Mag. and the lafianthus of La Marck being the fame plant, though La Marck makes no mention of the afcending ftem, and have preferred the former trivial name, as it feems to have the right of priority, on the high authority of Tournefort, an authority which we prefume La Marck will not be inclined to difpute. A native of Portugal. 34. C. *formofus*, Willd. 19. Bot. Mag. 264. (C. lafianthus, β. Lam.? Helianthemum humilius lufitanicum, halimi folio nigrore, magno flore luteo, Tourn. Inft. 250.) *Leaves* darkifh grey. Peduncles a little branched. Lam. *Flowers* yellow, thrice as large as thofe of C. halimifolius; petals marked with a dark purple fpot a little above the claw; peduncles and calyx cloathed with red hairs. Bot. Mag. We have almoft as little doubt with refpect to the identity of Curtis's and La Marck's plants. A native of Portugal. 35. C. *cheiranthoides*, Lam. 24. C. halimifolius β. Willd. (C. femina portulacæ marinæ folio anguftiore mucronato; Bauh. Pin. 465. C. folio halimi 2. Cluf. 1. p. 71). "Shrubby; leaves tomentous, oblong-lanceolate, narrower at the bafe; peduncles fhort, about two-flowered." *Stem* three feet high.

Leaves oppoſite, very white when young, a little three-nerved underneath, about an inch long. *Flowers* yellow. A native of Portugal. 36. C. *atriplicifolius*, Lam. 25. (C. halimi folio, flore luteo amplo, maximus, hiſpanicus, Barrel. Ic. 292. Helianthemum hiſpanicum, halimi folio ampliſſimo incano et nervoſo; Tourn. 250). "Shrubby; leaves petioled, egg-ſhaped, undulated towards the baſe, hoary on both ſides; flowers in racemes; peduncles and calyxes hiſpid." *Stem* from four to ſix feet high or more, upright. *Branches* into a regular head, whitiſh, cloathed with a very ſhort cottony down. *Leaves* oppoſite, nerved underneath, about an inch broad. *Flowers* yellow, not ſpotted, numerous, more than an inch in diameter, terminal, and from the forks of the upper branches; peduncles from three to five inches long; calyx-leaves three, ovate-acute concave; ſometimes two exterior ones very ſmall, narrow, acute: petals falling off ſoon after opening. Capſules even-ſurfaced, one-celled, three-valved. A native of Spain. 37. C. *elongatus*, Mart. 65. Willd. 21. Vahl. Symb. 1. p. 38. "Arboreſcent; leaves lanceolate, hoary; peduncles elongated, two-leaved; calyxes racemed, hirſute." *Stem* a foot high or more, upright, much branched. *Branches* ſhort; younger ones tomentous, hoary, beſet with yellowiſh ſcales. *Leaves* oppoſite, veinleſs, hoary, on both ſides, flat; younger ones doubled together, ſpreading at the tip; petiole very ſhort, with a few long hairs. *Flowers* yellow, with a duſky ſpot in the centre, nodding before they open; peduncles terminal, half a foot long, erect, not hoary, hairy, eſpecially near the bottom, with a pair of ſeſſile leaves towards the middle; pedicels towards the top of the peduncle, remote, filiform, quite ſimple, commonly five, with a bent joint at top; lower ones in pairs, the reſt alternate: calyx oblong, acuminate, ſmooth within; two leaves caducous. A native of Spain. 38. C. *involucratus*, Lam. 27. (Helianthemum hiſpanicum, halimifolio minimo; Tourn. Inſ. 251.) "Somewhat ſhrubby; leaves ſmall, inclining to egg-ſhaped, tomentous, ſeſſile; peduncles very ſhort, lateral; flowers with leafy involucre. *Stem* about a foot and half high, much branched. *Branches* ſlender, filiform, cottony, greyiſh. *Leaves* as ſmall as thoſe of C. ocymoides, n. 31, keeled, cinereous. *Flowers* ſmall, ſolitary; calyx villous. A native of Portugal. 39. C. *alyſſoides*, Lam. 28. "Somewhat ſhrubby; leaves oblong, egg-ſhaped, beſet with ſhort ſtiff hairs; younger ones ſomewhat hoary; older ones green: peduncles and calyxes hairy." *Stem* about a foot high, much branched. *Branches* ſpreading, ſlender, rough towards the ſummit, with whitiſh, rather woolly, hairs. *Leaves* oppoſite, narrowed towards the baſe, ſome obtuſe, others rather acute, a little roughened on the ſurface by ſtar-ſhaped hairs, as in many ſpecies of alyſſum. *Flowers* yellow, rather large; peduncles ſhort, two or three flowered, near the top of the branches, unopened flower-buds bright purple at their ſummit. A native of France and Spain. It varies in the ſize and ſhape of the leaves. 40. C. *roſeus*, Mart. 22. Lam. 29. Jacq. Hort. vol. iii. tab. 65. "Somewhat ſhrubby, almoſt without ſtipules, procumbent: leaves oppoſite, petioled, oblong, revolute at the edges, greeniſh on both ſides." *Stem* branched. *Branches* ſlender, weak, almoſt ſmooth, greeniſh, leafy near the top, two or three pair of the upper leaves narrower, furniſhed with ſtipules. *Flowers* roſe-coloured, in terminal racemes. 41. C. *alandicus*, Linn. Sp. Pl. 20. Mart. 24. Lam. 30. Willd. 38. Jacq. Auſt. 4. tab. 399. Hall. Helv. n. 1034. (C. helianthemos flore parvo luteo, Bauh. Hiſt. 2. p. 17. C. alpeſtris: Scop. Car. tab. 23. Chamæciſtus 2. Cluſ. Hiſt. 1. p. 73). "Somewhat ſhrubby, procumbent, leaves oppoſite, oblong, ſmooth on both ſides; petioles ciliated; petals emarginate." Linn. "Leaves ciliated." Lam. *Stem* ſmall, woody, branched from its baſe. *Branches* ſlender, villous, reddiſh, diverging. *Leaves* almoſt ſeſſile, ſmall. *Flowers* yellow, ſmall, peduncled, terminal, in ſhort almoſt corymbous racemes. A native of the ſouth of France, Switzerland, Auſtria, and the iſle of Eland. 42. C. *marifolius*, Linn. 19. Mart. 21. Willd. 32. Eng. Bot. 396. (C. myrtifolius, Lam. Var. β. γ. C. hirſutus, Hudſ. Flor. Ang. C. anglicus, Linn. Mant. 245. Lam. 33. Willd. 36. C. canus, Jacq. Auſt. 277. but not of Linnæus; Helianthemum alpinum, folio Piloſellæ minoris Fuchſii, Bauh. Hiſt. vol. ii. p. 19. H. ſerpylli folio incano, flore minore luteo, inodoro, Dill. Elth. vol. i. tab. 145. fig. 173. Chamæciſtus luteus, thymi durioris folio, Barrel. Ic. 44). "Somewhat ſhrubby; leaves oppoſite, petioled, oblong, tomentous underneath." Linn. *Roots* long, woody. *Stem* three or four inches high, woody, cylindrical, branched, decumbent at the baſe. *Leaves* ſpreading, flat, green above, hiſpid with depreſſed briſtles. *Flowers* yellow, rarely white, ſmall, ſcentleſs, in terminal racemes; racemes few-flowered, pubeſcent, bracteated; calyx hairy, with ſeveral brown ribs; petals inverſely egg-ſhaped, entire, ſlightly undulated; germ egg-ſhaped, ſmooth, with three or four hairy lines; ſtyle curved. A native of England, France, Spain, Italy, and Switzerland. 43. C. *canus*, Linn. 18. Mart. 19. Lam. 27. (C. myrtifolius var. α. Lam. 31. Jacq. Auſt. 3. tab. 277. Allion pedem. tab. 45. fig. 3. Chamæciſtus foliis myrti minoris incanis, Bauh. Pin. Tourn. 249. Chamæciſtus 3. Cluſ. Hiſt. 1. p. 74). "Somewhat ſhrubby, procumbent; leaves oppoſite, inverſely egg-ſhaped, villous, tomentous underneath; flowers ſomewhat umbelled." Linn. There is a variety with elliptic leaves, with a few ſcattered white hairs on each ſide, not tomentous underneath; calyxes always hirſute, in ſeſſile terminal umbels. (Helianthemum, ſerpylli folio villoſo, flore pallido. Barr. rar. tab. 366. H. alpinum ſerpylli folio nigricante et hirſuto. Seg. ver. 3. tab. 6. fig. 2). *Old ſtems* procumbent and naked; thoſe which bear leaves and flowers erect. *Flowers* deep yellow, from the axils of the upper leaves; calyxes tomentous. *Capſule* egg-ſhaped, ſomewhat acute, trigonous, nearly ſmooth, three-celled, three-valved, covered by the calyx. *Seeds* two or three in each cell, egg-ſhaped, acute, angular. Jacq. A native of the ſouth of Europe. 44. C. *italicus*, Linn. Sp. Pl. 17. Mart. 20. Lam. 32. Willd. 31. Helianthemum ſerpylli folio villoſo, flore pallido, Italicum. Barr. Ic. tab. 366). "Somewhat ſhrubby; leaves oppoſite, hiſpid; lower ones egg-ſhaped; upper ones lanceolate: branches ſpreading." *Stem* about ſeven inches high, erect. *Branches* oppoſite, long, ſpreading, ſomewhat deflexed, rufous, ſomewhat ciliated; lower ones petioled, upper ones nearly ſeſſile. *Flowers* pale yellow, in a terminal raceme; calyxes hiſpid; corollas ſcarcely emarginate. A native of Italy. Linnæus ſuſpects that it may be only a variety of the preceding ſpecies. 45. C. *vinealis*, Willd. 37. Hall. Helv. n. 1035. "Somewhat ſhrubby, procumbent; leaves petioled, oblong, obtuſe, hoary-tomentous underneath; flowers in racemes." It widely differs from C. marifolius in the form of its leaves, procumbent branches, and whole habit; and from C. celandicus in its leaves, being white with down underneath. A native of vineyards in Germany and Switzerland. 46. C. *echioides*, Lam. 34. "Somewhat ſhrubby; leaves linear, lanceolate, hairy on both ſides, rather rough, ſeſſile; racemes ſmall, hairy, recurved at the top." *Stem* half a foot high, erect, rough, with hairs, branched from the bottom almoſt to the top. *Leaves* oppoſite, acute, greyiſh. *Flowers* almoſt ſeſſile, in the axils of the bractes. A native of Spain, deſcribed by La Marck from a dried ſpecimen in the herbarium of Juſſieu. 47. C. *origanifolius*, Lam. 35. Willd.

33. Cavan. Ic. 3. tab. 262. fig. 1. "Somewhat ſhrubby; leaves oppoſite, petioled, egg-ſhapped, hairy on both ſides." *Stems* five or ſix inches high, much branched. *Leaves* reſembling thoſe of origanum, but much ſmaller; deſcribed by La Marck from ſpecimens without flowers preſerved in the herbaria of Juſſieu and Iſnard. *Flowers* yellow, ſcarcely longer than the calyx, only half as large as thoſe of C. marifolius; racemes from one ſide of the ſtem, in pairs, peduncled, hairy like the ſtem, Cavan. A native of Spain, near Cape St. Vincent. 48. C. *mollis*, Willd. 34. Cavan. Ic. 3. p. 32. "Somewhat ſhrubby; leaves roundiſh-egg-ſhaped, obtuſe petioled, flat, tomentous on both ſides, ſoft." *Stems* half a foot high, diffuſe, red, tomentous, branched. *Leaves* oppoſite, ſlightly nerved. *Flowers* three times as large as thoſe of the preceding ſpecies, in ſolitary terminal racemes. A native of Spain. 49. C. *dichotomus*, Willd. 35. Cavan. Ic. 3. tab. 263. fig. 1. "Somewhat ſhrubby, dichotomous; leaves egg-ſhapped, acute, ſmooth, revolute at the edges, oppoſite, petioled; flowers in racemes." *Leaves* ſmall, like thoſe of Thymus Piperella, on ſhort petioles. *Flowers* deep yellow, ſcarcely the ſize of thoſe of ſpergula nodoſa; racemes ſlender, few-flowered. A native of Spain. 50. C. *fumana*, Linn. Sp. Pl. 16. Mart. 18. Lam. 36. Willd. 26. (chamæciſtus ericæ folio luteus humilior; Bauh. Pin. 466. C. anguſtifolius, Ibid. Hall. Helv. n. 1032. C. minor, Barr. Ic. 286. and 2. 446. Helianthemum tenuifolium glabrum, luteo flore, per humum ſparſum, J. Bauh. 2. p. 18. Tourn. 249.) "Somewhat ſhrubby, procumbent; leaves alternate, linear, ſcabrous at the edges; peduncles one-flowered," Linn. *Stem* from five to eight inches high, woody, more or leſs upright, twiſted, branched. *Branches* ſlender, diffuſe, lower ones often procumbent. *Leaves* reſembling thoſe of Antirrhinum Linaria, but ſmaller, greeniſh; lower ones ſhorter and ſtiffer. *Flowers* yellow, on a ſolitary peduncle; calyx ſmooth, or cloathed with a very ſhort down, ſometimes with a purple tint, five-leaved; two outer leaves very ſmall, acute. *Capſules* three-celled, three-valved. A native of dry ſtony ground in Sweden, France, and Switzerland. 51. C. *calycinus*, Linn. Mant. 565. Mart. 16. Willd. 25. (C. fumana β. Lam. Deſfont. Fl. Atl. 1. tab. 105. C. ericoides, Cavan. Ic. 2. tab. 172. Chamæciſtus ericæ folio luteus elatior, Bauh. Pin. 466. Pluk. Alm. tab. 83. fig. 6.) "Somewhat ſhrubby, erect; leaves linear; peduncles one-flowered; calyxes three-leaved." *Stem* a foot high. *Branches* oppoſite, reddiſh. *Leaves* oppoſite, even-ſurfaced, obtuſely keeled underneath. *Flowers* yellow; peduncles terminal, ſolitary, ſcarcely longer than the leaves; calyx with three even-ſurfaced, equal leaves; ſtamens fifteen, very ſhort, yellow, all fertile; piſtil white; ſtigma warty. Nearly allied to the preceding. A native of the ſouth of Europe. 52. C. *ſcabroſus*, Mart. 59. Willd. 28. Hort. Kew. 2. p. 236. "Somewhat ſhrubby; leaves oppoſite, egg-ſhaped, hairy-ſcabrous, three-nerved; calyxes three-leaved." *Stems* decumbent, cylindrical, thickly cloathed with ſhort ſtellated hairs. *Branches* ſhort. *Leaves* an inch long, ſomewhat petioled. *Flowers* deep yellow, paler in the centre, terminal, ſomewhat panicled; calyx leaves equal, ovate-lanceolate, acuminate, pubeſcent on the outſide, with long ſtellated hairs; petals inverſely egg-ſhaped, ſomewhat retuſe, twice the length of the calyx. A native of Italy and Portugal. 53. C. *cinereus*, Willd. 29. Cavan. Ic. 2. tab. 141. "Somewhat ſhrubby; leaves oppoſite, egg-ſhaped, acute hoary; calyxes obtuſe; racemes panicled." Nearly allied to the preceding, but diſtinct. *Leaves* evidently petioled, veined. *Calyx* five-leaved, three of the leaves egg-ſhaped, obtuſe, two linear; petals quite entire, Cavan. 54. C. *ſyriacus*, Mart. 17. Mur. Syſt. 498. Jacq. Collect. 1. 98. (C. lavandula β. Lam. 54.) "Erect, leaves lanceolate, revolute; flowers racemed." *Leaves* acute, quite entire, nearly ſeſſile, alternate, ſomewhat villous, pale green. *Flowers* yellow; racemes terminal and axillary from the upper leaves, many-flowered, unilateral; calyx ſomewhat villous, pale green. Sent to Jacquin by Spielman in 1771. A native of the Levant. 55. C. *lævipes*, Linn. Sp. Pl. 15. Mart. 15. Lam. 37. Willd. 24. Jacq. Hort. 2. tab. 158. Ger. Prov. tab. 14. Pluk. Alm. tab. 84. fig. 6. (Helianthemum Maſſilienſe Coridis, fol. Tourn. 250.) "Somewhat ſhrubby, aſcending; leaves alternate, faſcicled, filiform, ſmooth; peduncles racemed," Linn. *Root* woody, creeping very much. *Stems* ſeveral, ſeven or eight inches long, woody when old, herbaceous when young, much branched. *Branches* ſlender, glaucous, quite ſmooth, except near the flowers, where they are often cloathed with ſhort ſeparate hairs. *Leaves* very numerous, alternate, ſetaceous-linear, from three to five inches long, glaucous; with each leaf come out two others, one-third ſhorter; between theſe, from the axil, other leaves come out ſucceſſively, ſo as to form a bunch ſitting cloſe to the branch. *Flowers* yellow, on long peduncles, terminal, ſcentleſs; calyx leaves five; three inner ones broad egg-ſhaped, acute, wrinkled longitudinally, variegated with white, green, and purple; petals egg-ſhaped, a little longer than the petals. *Capſule* obtuſely trigonous, obſcurely grooved, ſmooth, three-celled, three-valved. *Seeds* two in each cell, egg-ſhaped, convex on one ſide, angular on the other. A native of the ſouth of France. 56. C. *braſilienſis*, Lam. 38. (C. alternifolius, Willd. 39. Vahl. Symb. 1. p. 38.) "Somewhat ſhrubby; leaves alternate, ovate-oblong, villous, ſeſſile; peduncles one-flowered," Lam. Whole plant cloathed with rather long, white, almoſt ſilky hairs. *Stem* half a foot high or more, erect, a little zig-zag. *Leaves* villous on both ſides, flat, quite entire. *Peduncles* towards the top of the branch ſolitary, or ſometimes two or three together, one-flowered, in the axils of the leaves of the lower branches, ſpreading, twice the length of the leaf. A native of Brazil.

2. *Stem herbaceous.*

57. C. *globularifolius*, Lam. 39. Willd. 40. (Helianthemum Luſitanicum, globulariæ folio; Tourn. 250.) "Perennial; ſtem ſimple, nearly naked; root-leaves petioled ſpatulate, obtuſe." Root thick, woody. *Stem* from four to ſix inches high, furniſhed with two or three diſtant pairs of ſmall acute leaves. *Flowers* terminal, in a ſhort raceme. A native of Portugal. 58 C. *tuberaria*, Linn. Sp. Pl. 21. Mart. 25. Lam. 40. Willd. 41. Cavan. Ic. 1. tab. 67. (C. folio plantaginis, Bauh. Pin. 465. Helianthemum plantaginis folio, perenne, Tourn. 25. Buxb. Cent. 3. tab. 63. Tuberaria noſtras, et major mycoſis, J. Bauh. 2. p. 12.) "Perennial, root leaves egg-ſhaped, three-nerved, tomentous; ſtem leaves ſmooth, lanceolate; upper ones alternate," Linn. *Stem* half a foot high or more, commonly ſimple. *Root-leaves* ſpreading on the ground, white underneath; ſtem-leaves ſeſſile, diſtant. *Flowers* yellow, in a kind of corymb; two outer calyx-leaves ſhorter, lanceolate; three inner ones ovate-acuminate, concave. *Capſule* globular, three-valved. *Seeds* ovate-compreſſed, blackiſh, fixed to partitions oppoſite to the valves. A native of Spain, Italy, and the ſouth of France, cultivated by Miller in 1748. 59. C. *plantagineus*, Willd. 42. (C. ſerratus, Deſfont. Fl. Atl. 1. 416. excluding the ſynonym from Cavanilles. C. lanceolatus, Vahl. Symb. 2. p. 62?) "Herbaceous; leaves lanceolate, leſſened at both ends, three-nerved, hairy; racemes without bractes; petals finely toothed." Willd. "Inclining to ſhrub-

by

by near the bottom, herbaceous above; leaves lanceolate, three-nerved, hairy." Vahl. *Stem* a foot or a foot and a half high, sprinkled with long strait hairs, Willd.; branched at the base, Vahl. *Branches* quite simple, a short span long, ascending, smooth at the bottom, tomentous at the top, hoary their whole length, Vahl. *Leaves* two inches long, sessile, gradually smaller towards the top, opposite; two upper ones alternate, Vahl. *Root-leaves* oblong, acuminate, lessened into the petiole, three or five-nerved, hairy on both sides; the hairs on the under surface simple, scattered, close-pressed; on the upper more copious, stellated; stem-leaves opposite, lanceolate, sessile, three nerved, an inch and a half or two inches long, more hairy than the root-leaves, Willd. *Stipules* only to the last pair of leaves, Vahl. and Willd.; half an inch long, linear, hairy, Willd. *Bractes* none, Vahl. and Willd. *Raceme* terminal, Vahl. *Racemes* two at the top of the stem, Willd. *Flowers* yellow, without a central spot, Willd.; calyx five-leaved, Vahl. Willd. A native of Crete and the north of Africa; found by Vahl near Bizerta in Barbary. We have contrasted Willdenow's and Vahl's descriptions, that our readers may judge for themselves with respect to their identity. The only material difference seems to be, that Willdenow's plant is annual: Vahl's, perennial. 60. C. *serratus*, Willd. 43. Cavan. Ic. 2. tab. 175. fig. 1. "Leaves opposite, lanceolate, three nerved, hairy, viscous; root ones inversely egg-shaped; racemes without bractes; petals serrated." *Stem* only one-third the length of the preceding. *Leaves* obtuse. *Flowers* yellow, with a large black central spot. 61. C. *bupleurifolius*, Lam. 41. "Stem branched; stem-leaves lanceolate, three-nerved, even surfaced, smooth; upper ones alternate; flowers in corymbs." *Root* three or four inches long, slender, fibrous. *Stem* herbaceous, four inches high, smooth, leafy. *Branches* simple, a little villous towards the top. *Root leaves* oblong, lessened towards the base, slightly three-nerved, beset with short hairs; stem-leaves sessile, very acute, even-surfaced, smooth, sometimes, but rarely, furnished with some loose hairs underneath, most of them opposite, gradually diminishing in size towards the top. *Flowers* in short peduncles, in a small close corymb. Communicated to La Marck by Vahl, who found it in Spain. It seems to differ from his lanceolatus chiefly in its completely herbaceous stem, and its comparatively smooth leaves. 62. C. *guttatus*, Linn. Sp. Pl. 22. Mart. 26. Lam. 42. Willd. 44. Curt. Flor. Lond. fasc. 6. tab. 33. Eng. Bot. tab. 544. (C. flore pallido, punicante macula insignito, Bauh. Pin. 465. Rai. Syn. 342. C. annuus flore guttato, J. Bauh. Hist. vol. ii. p. 14. Helianthemum flore maculoso, Tourn. 250. Colum. Ecphr. tab. 77. fig. 1.) "Leaves opposite, lanceolate, three-nerved; racemes nearly naked." Dr. Smith. *Root* annual, small, fibrous. *Stem* near a foot high, erect, simple or branched, square, hairy; hairs white, spreading. *Leaves* rather obtuse, quite entire, hairy on both sides, somewhat viscid. *Flowers* yellow; racemes terminal, simple, unilateral, hairy, often without bractes, but sometimes with solitary lanceolate ones at the base of the pedicels; calyx glandular, hairy; petals unequally crenate, with an elegant purple spot near the base; stigma sessile. *Capsule* egg-shaped, three-celled. *Seeds* attached to the partitions, which are fixed to the middle of the valves, Dr. Smith. La Marck mentions two varieties; one smaller with linear-lanceolate leaves; the other larger with ovate-acute or ovate-lanceolate stem-leaves. A native of Italy, the south of France, and the isles of Jersey and Man. 63. C. *canadensis*, Linn. Sp. Pl. 23. Mart. 27. Lam. 43. Willd. 45. "All the leaves alternate, lanceolate; stem ascending." A native of Canada, observed by Kalm. 64. C. *alternifolius*, Mart. 63. Vahl. Symb. 1. 38. "Somewhat shrubby; leaves alternate; peduncles lateral and terminal, generally solitary, one-flowered." *Stem* erect. *Branches* slender, villous, brown. *Leaves* sessile, oblong, erect, flat, quite entire, villous on both sides. *Flowers* solitary towards the top, sometimes two or three together in the axils of the leaves on the lower branches; peduncles spreading, double the length of the leaf, villous, a little thicker at the end, with two linear caducous leaves at the top; calyxes egg-shaped, acute, hirsute. A native of Brazil. It has the calyx and inflorescence of salicifolius n. 103, but differs in being shrubby. 65. C. *medius*, Mart. 50. Allion pedem, n. 1657. "Leaves ovate-lanceolate, wrinkled, petioled, finely toothed." *Stems* shrubby, reddish, viscid. *Leaves* green. *Flowers* pale yellow; peduncles solitary, axillary and terminal. A native of the county of Nice.

† † *With stipules.*

66. C. *squamatus*, Linn. Sp. Pl. 27. Mart. 32. Lam. 44. Willd. 51. Barr. Ic. 327. Bocc. Mus. 2. tab. 64. fig. 3. "Stem somewhat shrubby; leaves covered with orbicular scales." Linn. *Stem* six or seven inches long, rather erect, tetragonous near the bottom. *Leaves* oval-lanceolate, thickish, petioled, opposite, some three together; scales silvery, with a hollow point in the middle. *Stipules* extremely small, acute, shrivelling, sessile. *Flowers* yellow, terminal, in small racemes, on short thick-set peduncles. A native of dry hills in Spain. 67. C. *lippii*, Linn. Mant. 245. Mart. 33. Lam. 45. Willd. 52. Vahl. Symb. n. 39. (C. stipulatus, Forsk. Desc. 100.) "Somewhat shrubby, erect; leaves alternate and opposite, lanceolate, scabrous; spikes unilateral." Linn. *Stem* from four to six inches high, cylindrical, pubescent, whitish, bifid, or but little branched. *Branches* white, alternate, often zig-zag. *Leaves* generally alternate, petioled, oblong, obtuse, pale green above, with short hairs, whitish and slightly cottony underneath. *Stipules* small, narrow-lanceolate, opposite, nearly the length of the petioles. *Flowers* yellow; racemes or spikes short, solitary, opposite to the leaves, sessile, scarcely opening, but appearing almost like buds till the fruit opens; petals smaller, scarcely longer than the leaves of the calyx. *Capsules* nearly globular, almost covered by the calyx. A native of Egypt. 68. C. *sessiliflorus*, Willd. 53. Desfont. Fl. Atl. 1. p. 427. tab. 106. "Somewhat shrubby, erect; leaves alternate and opposite, linear, hoary, revolute at the margin; spikes unilateral." *Stem* a foot or two feet high, erect, much-branched. *Leaves* somewhat petioled, rather obtuse. *Stipules* small, linear. *Flowers* yellow, a little longer than the calyx, sessile. *Bractes* minute, linear-lanceolate. *Calyx* pubescent. *Capsule* roundish, pubescent, longer than the calyx, Desfont. 69. C. *ellipticus*, Willd. 54. Desfont. Fl. Atl. 1. tab. 107. "Somewhat shrubby, erect; leaves opposite, elliptic, hoary, revolute at the edges; spikes unilateral." *Stem* a foot or two feet high, branched. *Branches* pubescent. *Leaves* on short petioles, cloathed on both sides with very short and very dense hairs. *Stipules* growing by fours, small, linear. *Flowers* yellow, small, sessile; petals a little longer than the calyx. *Capsule* roundish, pubescent, longer than the calyx. A native of the country about Algiers. 70. C. *canariensis*, Murray Syst. 499. Mart. 36. Lam. 46. Willd. 59. Jacq. Ic. 1. tab. 97. Jacq. Misc. 2. p. 339. "Procumbent; leaves somewhat egg-shaped, alternate and opposite; racemes erect." Jacq. "Procumbent; leaves opposite and alternate, pubescent, glaucous, oblong-inversely egg-shaped, acute; racemes unilateral." Willd. *Root* fibrous. *Stem* six or seven inches long, slender, woody, branched, slightly pubescent, reddish brown near the bottom.

bottom. *Branches* alternate, whitiſh and a little cottony towards the top. *Leaves* petioled, pale green, almoſt ſmooth above, pubeſcent and reflexed at the edges underneath. *Stipules* narrow, almoſt ſetaceous, ſhorter than the petioles, hooked, villous, caducous. *Flowers* yellow, peduncled; racemes an inch and a half long; peduncles cottony; calyxes with projecting ſtriæ. A native of the Canary iſlands. 71. C. *ſerpyllifolius*, Linn. Sp. Pl. 30. Mart. 38. Willd. 60. (Chamæciſtus repens ſerpyllifolia lutea, Bauh. Pin. 466.) "Somewhat ſhrubby; leaves oblong; calyxes even-ſurfaced." A native of mountains in the ſouth of Europe. La Marck has omitted this ſpecies. 72. C. *violaceus*, Willd. 61. Cavan. Ic. 2. tab. 147. "Somewhat ſhrubby, aſcending; leaves oppoſite, ſomewhat tomentous, linear, obtuſe, attenuated at the baſe, revolute at the edges; calyxes even-ſurfaced." *Flowers* white, in long erect racemes; calyxes of a reddiſh violet colour. 73. C. *linearis*, Willd. 62. Cavan. Ic. 3. tab. 216. "Somewhat ſhrubby, aſcending, a little tomentous; leaves linear, obtuſe, petioled, revolute at the edges; calyxes even-ſurfaced. *Leaves* petioled, not attenuated at the baſe, thrice the length of thoſe of the preceding ſpecies. *Flowers* white; the two ſmaller calyx-leaves acute, not obtuſe; petals inverſely-egg-ſhaped. In theſe reſpects, its white flowers excepted, and in its whole habit, it differs from C. violaceus. A native of Spain. 74. C. *lævis*, Willd. 63. Cavan. Ic. 2. tab. 145. fig. 1. "Somewhat ſhrubby, erect, leaves linear, ſeſſile, ſmooth, revolute at the edges, keeled; calyxes even-ſurfaced." *Leaves* acute at the tip; lower ones crowded, ſhorter; upper ones a little ſpreading. *Stipules* linear. *Flowers* deep yellow, longer than the calyx: two ſhorter calyx-leaves awl-ſhaped. A native of Spain. 75. C. *ſtrictus*, Willd. 64. Cavan. Ic. ii. tab. 263. fig. 2. "Somewhat ſhrubby, erect; leaves hoary, linear-awl-ſhaped, revolute at the edges; racemes unilateral; calyxes ſmooth." Willd. *Stem* half a foot high; branches numerous, oppoſite, ſtiff, and ſtraight, cloathed with a ſhort hoary down. *Leaves* oppoſite, nearly ſeſſile, with a few hairs at the tip. *Flowers* white, larger than the calyx; calyx ſtriated. 76. C. *ſurrejanus*, Linn. Sp. Pl. 28. Mart. 34. Lam. 47. Willd. 55. (C. helianthemum δ. Hudſ. Flor. Ang. 233. Helianthemum vulgare, petalis florum perangustis, Dill. in Rai. Synop. 341. Hort. Elth. tab. 145. fig. 174.) "Somewhat ſhrubby; leaves ovate-oblong, hairy underneath, dotted; petals lanceolate. *Stems* proſtrate, ſimple, leafy, cylindrical, cloathed with depreſſed matted hairs. *Leaves* petioled, obtuſe, flat, quite entire, nearly naked above, hairy, and ſtudded with hollow points underneath, green on both ſides, not hoary. *Stipules* two, lanceolate, ciliated. *Flowers* yellow, erect, racemes terminal, ſolitary, ſimple, many-flowered, recurved, pubeſcent, bracteate; calyx hairy, with red nerves; petals very narrow, acute, generally longer, but ſometimes ſhorter than the calyx. *Capſule* one celled, or obſcurely three-celled. Dr. Smith. Found by Edward du Bois near Croydon, in Surrey, whence Linnæus formed its trivial name. It does not appear to have been obſerved wild in any other ſituation, either in or out of England. It is diſtinguiſhed from C. *helianthemum*, to which it is nearly allied, by the remarkable form of its petals. 77. C. *polyanthos*, Willd. 56. Desfont. Flor. Atl. i. tab. 108. "Somewhat ſhrubby; lower leaves hoary underneath; ſtem ones green on both ſides, ciliated; calyxes hiſpid; racemes panicled. *Stems* a foot high, numerous, cylindrical, villous, rough, with tubercles. *Leaves* oppoſite, petioled, obtuſe, veined underneath; lower ones egg-ſhaped, ſmaller; upper ones ovate-oblong, or lanceolate. *Stipules* four, petioled, linear-lanceolate, rather obtuſe, longer than the petiole. *Flowers* yellow, ſmall, longer than the calyx; racemes erect, drooping before the flowers open; peduncles filiform; pedicels capillary; bractes linear, ſhorter than the pedicels; calyx cloathed with numerous, white, ſoft, ſpreading hairs. *Capſule* ſmall, villous at the tip. A native of the north of Africa. 78. C. *glaucus*, Willd. 57. Cavan. Ic. iii. tab. 261. "Somewhat ſhrubby, aſcending; leaves tomentous, glaucous, revolute at the edges; lower ones egg-ſhaped, upper ones lanceolate; racemes unilateral." *Petals* yellow, longer than the calyx, roundiſh, crenulate at the edges. A native of Spain. 79. C. *croceus*, Willd. 75. Desfont. Flor. Atl. i. tab. 110. "Somewhat ſhrubby, pubeſcent, cloathed with very ſhort ſtellated hairs; leaves elliptic, obtuſe." A foot high. *Stems* numerous, erect, cylindrical, tomentous, ſomewhat hoary. *Leaves* oppoſite, petioled, ſomewhat hoary underneath, revolute at the edges, pubeſcent on both ſides; with cloſe-ſet ſhort ſtellated hairs; lower ones ſmaller, roundiſh, middle ones elliptic, obtuſe; upper ones lanceolate, ſomewhat acute. *Stipules* four, awl-ſhaped, a little longer than the petiole. *Flowers* ſaffron-coloured; racemes, before the flowers open, convolute; bractes lanceolate, pubeſcent, the length of the pedicels, calyxes pubeſcent, angular, yellowiſh; petals quite entire. Nearly allied to the preceding, but diſtinct. A native of Spain, and the north of Africa. 80. C. *nummularius*, Linn. Sp. Pl. 29. Mart. 35. Lam. 48. Willd. 58. (Helianthemum ad nummularia accidens, J. Bauh. Hiſt. ii. p. 20. Tourn. 249. Ciſtus humilis, ſ. chamæciſtus nummulariæ folio, Mag. Monſp. 293.) "Somewhat ſhrubby; lower leaves orbicular; upper ones egg-ſhaped." Linn. *Stems* long, trailing, much branched. *Leaves* oppoſite, petioled, ſlightly villous; lower ones whitiſh underneath; all of them green on the upper ſurface. *Stipules* three, narrow, erect. *Flowers* large, white, in terminal racemes. Found by Magnol on Mount Capouladon near Montpelier. J. Bauhin received it from Baſil. 81. C. *ciliatus*, Willd. 70. Desfont. Flor. Atl. i. tab. 109. "Somewhat ſhrubby, procumbent; branches tomentous; leaves narrow, lanceolate, villous; calyxes membranous, with ciliated angles." *Stems* a foot high, branched at the baſe. *Branches* ſingle, cylindrical, hoary. *Leaves* oppoſite, on ſhort petioles, hirſute on the upper ſurface, caneſcent and tomentous underneath, revolute at the edges. *Stipules* four, linear, longer than the petiole. *Flowers* roſe-coloured; racemes terminal, revolute before the flowers open; bractes linear-lanceolate; two outer leaves of the calyx ſmall, linear. *Capſule* roundiſh, covered by the calyx. A native of ſandy hills in the north of Africa. 82. C. *anguſtifolius*, Murray Syſt. Veg. p. 500. Mart. 43. Willd. 71. Jacq. Hort. iii. tab. 53. "Somewhat ſhrubby, diffuſe; leaves lanceolate; calyxes hirſute." *Root* branched. *Stem* cylindrical, woody, branched from the baſe; younger branches, leaves, ſtipules and racemes ſlightly villous and hoary. *Leaves* oppoſite, ſomewhat acute, quite entire, rough on both ſides, on ſhort petioles. *Flowers* yellow, orange-coloured in the centre; racemes terminal, many-flowered, erect; pedicels bent back as the fruit ripens; ſtipules and bractes deciduous; outer calyx-leaves linear; inner ones egg-ſhaped, acute, nerved; petals either quite entire, or crenulate about the edge. *Capſule* hirſute, egg-ſhaped, Jacq. 83. C. *helianthemum*, Linn. 33. Mart. 44. Lam. 49. Willd. 72. Curt. Flor. Lond. Faſc. 5. tab. 36. Flor. Dan. tab. 101. Eng. Bot. 1321. (Chamæciſtus vulgaris, flore luteo, Bauh. Pin. 465. Helianthemum vulgare, Tourn. 248. Gært. tab. 76. fig. 11.) "Somewhat ſhrubby; ſtipules lanceolate; leaves oblong, revolute, ſomewhat hairy." Linn. "Somewhat ſhrubby, procumbent; leaves oblong, revolute, hoary underneath; calyxes ſomewhat hirſute." Lam. *Stems* generally ſimple, cylindrical,

cylindrical, leafy, hairy. *Leaves* small, various in size, elliptic, obtuse, on short petioles, entire green, and cloathed with simple hairs above; white, downy, and hairy underneath. *Stipules* acute, green on both sides, ciliated. *Flowers* bright yellow, in terminal racemes, on hairy peduncles; calyx coloured with hairy ribs; petals roundish, obscurely crenate; stamens the length of the style, erect; when touched with a pin or bristle, retiring from the style, and lying down in a spreading form upon the petals; but this can be seen only in calm warm weather, and when the flowers have not been ruffled by insects. Dr. Smith. A native of England, and other parts of Europe, chiefly on a calcareous soil, and flowering in July and August. It varies with paler and with white flowers. Willdenow makes C. *roseus* of La Marck with rose-coloured flowers only a variety. 84. C. *grandiflorus*. Mart. 51. Scop. Carn. n. 648, tab. 25. Allion. Ped. n. 4. (Helianthemum alpinum, vulgari simile, foliis latioribus; Bauh.) "Somewhat shrubby; leaves lanceolate, villous on both sides, acuminate; stipules longer than the calyx." *Stem* about six inches long, villous. *Leaves* an inch long. *Flowers* yellow, racemed; peduncles and calyxes villous; outer calyx-leaves linear; inner twice as long; petals almost half an inch in length. Allioni doubts whether it be distinct from the preceding species; but Scopuli asserts that it differs in the whole appearance of the flower, length of the racemes, and hardness of the leaves. 85. C. *mutabilis*, Mart. 45. Willd. 73. Jacq. Ic. 1. tab. 99. Misc. 2. p. 340. (C. hispidus γ, Lam. who says it is the effect only of cultivation.) "Somewhat shrubby, procumbent; stipules lanceolate; leaves oblong, smooth, flat." Native country unknown. *Flowers* either pale yellow or rose-coloured. 86. C. *hirtus*, Linn. Sp. Pl. 34. Mart. 46. Willd. 76. "Somewhat shrubby, leaves egg-shaped; calyxes hispid," Linn. *Stem* erect, much-branched. *Leaves* very narrow, opposite, revolute, bright green above, hoary underneath. *Flowers* white, large, in small terminal racemes. A native of Spain and the south of France, cultivated by Miller in 1759. Professor Martyn quotes C. rosmarini foliis of Allioni as a synonym; but the calyx of Allioni's plant is only whitish, with nothing rough or hairy about it. It seems therefore to be a distinct species. 87. C. *barbatus*. Lam. 50. (C. pilosus β, Willd. Helianthemum f. Cistus humilis, flore sampsuci, capitulis valde hirsutis; J. Bauh. 2. p. 20. Tourn. 249.) "Somewhat shrubby, erect; leaves egg-shaped, hairy, green on both sides; racemes hirsute-bearded." *Leaves* opposite, petioled, villous above and underneath. *Flowers* yellow, in terminal racemes, less loose than those of C. helianthemum. Lamarck suspects that this plant may be one and the same with the preceding, excluding the synonyms quoted by Linnæus; but C. hirtus of Linnæus, or at least of Miller, has its leaves hoary underneath; whereas those of Lamarck's barbatus are green on both sides. 88. C. *glutinosus*, Linn. Mant. 246. Mart. 39. Lam. 51. Willd. 65. Cavan. Ic. 2. tab. 145. fig. 2. (Chamæcistus incanus, tragorigani folio; Barrel. Ic. 415. Helianthemum folio thymi incano; J. Bauh. 2. p. 19 Tourn. 249.) "Somewhat shrubby; leaves linear, opposite and alternate; peduncles villous, glutinous." Five or six inches high. *Stem* much branched from the bottom. *Branches* regular, pubescent, viscous. *Leaves* of a cinereous green colour, small, somewhat acute, revolute, not much more than three lines long. *Flowers* yellow, small, in a loose terminal raceme. *Capsules* small, globular, three-celled. Lam. A native of the south of Europe. 89. C. *thymifolius*, Linn. Sp. Pl. 31. Mart. 40. Willd. 66. (C. glutinosus β. Lam. Chamæcistus luteus, thymi folio, oliganthes; Barrel. Ic. 444. Cistus alpina humilis, foliis thymi minutissimis; Pluk. tab. 84. fig. 5.) "Somewhat shrubby, procumbent; leaves linear, opposite, very short, clustered." Linn. A native of Spain and the south of France. 90. C. *ferrugineus*, Lam. 52. (C. minor thymi folio, flore ferrugineo; Burr. rar. tab. 285.) "Somewhat shrubby; leaves alternate, lanceolate, flat; lower ones somewhat linear; peduncles lateral, one-flowered." *Root* woody, long, rather thick. *Stems* from five to eight inches long, somewhat woody, diffused, leafy, pubescent towards the top. *Leaves* small, acute, greyish green. *Stipules* two, opposite, very small, acute. *Flowers* ferruginous or reddish yellow, solitary; peduncles and calyxes pubescent. *Capsules* globular, three-celled. A native of Spain. 91. C. *arabicus*, Linn. Sp. Pl. 37. Mart. 49. Willd. 79. Desfon. Flor. Atl. 1. p. 419. Vahl. Symb. 2. tab. 35. (C. ferrugineus; β. Lam.? Helianthemum creticum, linariæ folio, flore croceo; Tourn. Cor. 18.) "Somewhat shrubby; leaves alternate, lanceolate, flat, even-surfaced." Linn. "Somewhat shrubby, procumbent; leaves linear; those of the peduncles alternate, those of the smaller branches crowded." Vahl. *Stem* branched from the bottom. *Branches* often a foot long, at first procumbent, afterwards ascending, slender, cylindrical, smooth; branchlets numerous, alternate, distant, widely spreading; lower ones barren; upper ones floriferous, quite simple, elongated, cinereous, pubescent. *Leaves* of the barren branchlets crowded, marked with two lines, declining, linear, stiffish, without veins, rather obtuse; upper ones tomentose-ash-coloured. *Stipules* minute, egg-shaped. *Leaves* of the floriferous branchlets broader, longer, pubescent. *Stipules* lanceolate. *Flowers* three or four in a terminal raceme, without bractes; pedicels distant, hairy, and somewhat viscid towards the top, a little thicker under the flower; calyx hairy, somewhat viscous; inner leaves three-nerved, membranous between the nerves; outer ones lanceolate. Vahl. Vahl's plant came from Spain. According to La Marck, Tournefort's plant from the island of Candy differs from the preceding species only in being larger, less pubescent, with a little longer leaves; but he is dubious whether it be C. arabicus of Linnæus. 92. C. *racemosus*, Linn. Mant. 76. Mart. 42. Lam. 53. Willd. 69. Vahl. Symb. 1. p. 39. Cavan. Ic. 2. tab. 140. (C. lavandulæ folio, thyrsoides; Barr. ic. 293.) "Somewhat shrubby; leaves lanceolate-linear, tomentous underneath." Linn. "Somewhat shrubby; leaves lanceolate-linear, tomentous underneath; racemes terminal, unilateral; calyxes even-surfaced, angular. Lam. *Stem* nine or ten inches high. *Branches* numerous, erect, very slender, whitish, and slightly cottony towards the top. *Leaves* opposite, narrow, about an inch long, revolute, cottony and whitish underneath, green above, with a longitudinal furrow. *Stipules* awl-shaped. *Flowers* in long, terminal, upright racemes. Lam. A native of Spain. 93. C. *lavandulifolius*, Mart. 64. Lam. 54. Willd. 68. Vahl. Symb. 1. p. 39. Desfont. Fl. Atl. 1. p. 47. (C. folio spicæ; Bauh. Pin. 465. C. lavandulæ latifoliæ folio. Barr. ic. 288. Good. Helianthemum lavandulæ folio, Tourn. 249.) Somewhat shrubby, erect; leaves lanceolate, revolute, somewhat hoary; racemes terminal, incurved; flowers crowded." Lam. *Stem* about a foot high, woody. *Branches* opposite, upright, whitish near the top. *Leaves* opposite. *Stipules* four, small, villous, narrow, acute. *Flowers* yellow, small; racemes terminal, a little branched, at first short and curved; calyxes whitish, a little cottony; its leaves bordered with white silky hairs. When not in flower, the whole plant greatly resembles common lavender. A native of Spain, the south of France, Tunis, and Syria. According to La Marck, C. Syriacus of Jacquin and Martin, described above, n. 54. is only a variety of this species, with

with larger, lefs revolute, and not lefs white leaves. Willd. gives it as a fynonym, and not even a variety. 94. C. *appenninus*, Linn. Sp. Pl. 35. Mart. 47. Willd. 77. (C. hifpidus β. Lam. 55. Helianthemum faxatile, foliis & caulibus incanis oblongis, Apennini montis; Retz pug. tab. 8. Dill. Elt. 176. "Shrubby, fpreading; leaves lanceolate, hairy." *Stem* a foot high, branched. *Leaves* green and rough, with hairs on the upper furface, hoary underneath. *Flowers* white. 95. C. *hifpidus*, Lam. 55. (Chamæciftus folio thymi, incanus. Bauh. Pin. 466. Helianthemum flore albo, folio angufto, hirfuto. J. Bauh. 2. p. 17. Tourn. Inft. 248. "Somewhat fhrubby, erect; leaves oblong, hairy on the upper furface, tomentous underneath; calyxes hairy-hifpid." Lam. *Stems* near a foot high, diffufe, branched. *Branches* flender, whitifh, and villous near the top. *Leaves* oppofite, revolute. *Flowers* white, in terminal racemes. A native of Italy and the fouth of France, diftinguifhed from the next fpeci s by its very hifpid calyxes. 96. C. *pilofus*, Linn. 32. Allion. ped. n. 1672, tab. 45. fig. 1, 2. "Somewhat fhrubby, rather erect; leaves linear, two-furrowed, underneath hoary; calyxes fmooth and even." *Flowers* white; bractes folitary, at the fide of the pedicels. A native of Spain, Piedmont, and the fouth of France; cultivated by Miller in 1759. 97. C. *fœtidus*, Willd. 74. Jacq. ic. 1. tab. 98. Mifc. 2. p. 341. "Somewhat fhrubby, procumbent; ftipules lanceolate; leaves oblong, hirfute, fcabrous." *Flowers* white. The whole plant has the fœtid fmell of bryony. 98. C. *polifolius*, Linn. Sp. Pl. 36. Mart. 48. Lam. 56. Willd. 78. (C. humilis, Pluk. Alm. 107. tab. 23. fig. 6. Helianthemum foliis poli montani; Tourn. Inft. 249. Dell. Elt. tab. 145. fig. 172.) "Somewhat fhrubby, procumbent, with a ftarlike pubefcence; leaves oblong, revolute, tomentous-hoary underneath." Dr. Smith. The habit of C. helianthemum, but very diftinct. *Stems* from five to eight inches long, tomentous, with clofe-preffed hairs. *Leaves* green above, with fcattered ftarlike hairs, white underneath, and denfely cloathed with ftarlike down, marked with a very prominent nerve. *Flowers* white; calyx hairy, chiefly on the nerves; hairs bundled or ftarlike. *Capfule* obfoletely three-celled. Dr. Smith. A native of England and France. 99. C. *fplendens*, Lam. 57. (Helianthemum album Germanicum, Tabern. ic. 1002. Tourn. 248.) "Somewhat fhrubby, erect; leaves lanceolate, linear, green and fhining above, hoary underneath; calyxes fmooth and even." About a foot high. *Stem* branched from the bottom. *Branches* very flender, cylindrical, fmooth, chiefly erect. *Leaves* oppofite, petioled, a little revolute, near an inch long. *Flowers* white, fmall, peduncled, in terminal racemes; calyxes greenifh, with brown nerves; claws of the petals and ftamens yellow. A native of Germany and France.

(2.) *Stem herbaceous.*

100. C. *punctatus*, Willd. 46. "Erect, pubefcent; raceme terminal; leaves oppofite, oblong; lower ones inverfely egg-fhaped." *Root* annual. *Stem* about three inches high. *Branches* erect, ftiff, oppofite, fimple, fhorter than the ftem. *Leaves* opp fite, petioled; lower ones obtufe; upper ones rather acute. *Stipules* linear-lanceolate. *Flowers* in an elongated, terminal raceme; peduncles one-flowered, erect; bracte ovate-lanceolate, fmall, not at the bafe, but about the middle of the peduncle; outer-calyx-leaves linear, fpreading. Defcribed by Willdenow from a dried fpecimen; native country unknown. 101. C. *ledifolius*, Linn. Sp. Pl. 24. Mart. 28. Lam. 58. Willd. 47. (C. ledi folio, Bauh. Pin. 465. Lob. Ic. 2. 118. Helianthemum ledi folio, Tourn. 249.) "Erect, fmooth; flowers folitary, nearly feffile, oppofite to the ternate leaf." Linn. "Pubefcent; leaves lanceolate; peduncles erect, fhorter than the calyx." Dr. Smith. *Root* annual, fmall, a little branched. *Stem* from fix to nine inches high, rather erect, generally fimple, fometimes branched from the bottom, cylindrical, hirfute, leafy, few-flowered. *Leaves* oppofite, petioled, obtufe, quite entire, narrowed at the bafe, pubefcent on both fides. *Stipules* two, lanceolate, acute, three times fhorter than the leaf. *Flowers* yellow, oppofite to the leaves, erect, on fhort peduncles; calyx-leaves acuminate, nerved, hirfute; petals fhorter than the calyx, foon falling off. *Capfule* about the length of the calyx, fmooth, one-celled. Dr. Smith. According to La Marck, there are four ftipules, growing in pairs, and almoft as large as the leaves near the top of the plant. A native of England and France. 102. C. *niloticus*, Linn. Mant. 246. Mart. 30. Willd. 49. (C. ledifolius, β, Lam.) "Erect, fomewhat tomentous; flowers in racemes, folitary, feffile, oppofite to the leaves." *Root* annual. *Stem* a foot high, fomewhat woody, cylindrical. *Branches* next the root afcending, fhorter than the ftem; towards the top of the ftem alternate, erect, few. *Leaves* oppofite, petioled, elliptic, fpreading, fomewhat tomentous, veined, longer than the joints of the ftem. *Stipules* four, fword-fhaped, half the length of the leaf, permanent. *Flowers* yellow; in a terminal, erect, ftiff raceme, alternate, accompanied by a leaf and two ftipules, fimilar to thofe of the ftem-leaves; calyx five-leaved, erect; the three inner leaves three-nerved, acuminate, two outer ones linear, fhorter, fpreading. A native of Egypt. Linn. La Marck afferts that it is merely a variety of the preceding, only a little larger, and without any pretenfions to be received as a diftinct fpecies. 103. C. *falicifolius*, Linn. Sp. Pl. 25. Mart. 29. Lam. 59. Willd. 48. (C. folio falicis, Bauh. Pin. 465. Lob. Ic. ii. p. 118. Helianthemum falicis folio, Tourn. Inft. 249. H. annuum humile, foliis ovatis, flore fugaci, Seg. Ver. iii. tab. 6. fig. 3. good.) "Spreading, villous; flowers racemed, erect; pedicels horizontal." Linn. *Root* annual. *Stem* branched from the bottom. *Branches* fpreading, about five inches long, cylindrical, pubefcent. *Leaves* petioled, fmall, oppofite and alternate, oval-oblong, rather obtufe, flightly wrinkled, cloathed with a fhort fomewhat woolly down. *Flowers* fmall, pale yellow or whitifh; peduncles alternate, lateral, and terminal, longer than the calyx, one-flowered. *Capfules* fmaller than thofe of the preceding fpecies, fcarcely longer than the calyx. A native of Spain, Portugal, and the fouth of France. 104. C. *ægyptiacus*, Linn. Sp. Pl. 26. Mart. 31. Lam. 60. Willd. 50. Jacq. Obf 3. tab. 68. "Erect; leaves linear-lanceolate, petioled; calyxes inflated, larger than the corolla." Linn. *Stem* five or fix inches high, very flender, generally fimple, but fometimes branched from the bottom, pubefcent towards the top. *Leaves* about an inch long, oppofite, on fhort peduncles; ending in a weak point, fmooth above, almoft imperceptibly villous underneath. *Flowers* yellowifh, very fhort, peduncled, alternate, drooping, in a terminal raceme; two outer calyx leaves very fmall, half open; the three others converging into fomething like an inflated, tranfparent bladder, remarkable for its ftrong, ciliated, purplifh nerves. *Capfules* enclofed in the calyx. A native of Egypt. In this now very extenfive intricate genus, Linnæus has thirty-feven fpecies in the Species Plantarum, with the addition of fix others in the two Mantiffas; La Marck, fixty; Profeffor Martyn, in his edition of Miller's Dictionary. fixty-fix; and Willdenow, feventy-nine.

Cistus *indicus*, Herm. Lugb. Rai. Hift. See Azalea *indica*.

Cistus *pumilus montis Baldi*, J. Bauh. —— *chamærhododendros foliis confertis*, Pluk. Alm. See Rhododendrum *chamæcistus*.

Obs. Ancient authors differ much from each other in their application of the terms Cissus and Cistus. Cissus, Κισσος, in the Attic dialect Κιττος, is the proper Grecian name for the common ivy, hedera helix of Linnæus. Theophrastus, as might be expected, gives it in its Attic form, and so clearly describes it, as to leave no doubt of the plant intended. Of the plants which constitute the present Linnæan genus Cissus, none of which are natives of Greece, he appears to have had no knowledge. They resemble the common ivy in nothing but in being climbers; and even in that single point the resemblance is not complete, as they attach themselves to other bodies for support in a very different manner.

The word Κιττος occurs twice in our present copies of the "Historia Plantarum, lib. 6. cap. 1." near the end, and in immediate connection with it, cap. 2. at the beginning. But the critics suppose, with great probability, that the text is corrupt, and that the genuine reading is Κιστος. For, to say nothing of the improbability, that the citizen of Athens should depart from his native dialect, which he had elsewhere constantly preserved, there is a moral certainty that he could not have meant the common ivy, no less from the place which he has assigned it in his system, than from the characters which he has attributed to it. He had already described the common ivy, κισσος, or, as he spells it, κιττος, in that part of his work which treats of trees; an arrangement to which he was led by its thick arboreous stem or trunk when it is grown old. He is now proceeding to shrubs and herbaceous plants, *καὶ γαρ κισσυ* (lege *κιστυ*) *δυο γενη διαιρετι, το μεν ἄρρεν, το δε θηλυ. τῳ το μεν μειζον καὶ σκληροτερον καὶ λιπαρωτερον φυλλον εχειν, καὶ το ανθος επιπορφυριζον, αμφω δε ὁμοια αγριοις (ροδοις)· πλην ελαττω καὶ ασσμα* "For there are two kinds of cistus, one male, the other female; the former having larger, firmer and more succulent leaves, and a purplish flower; but both resembling the wild rose, though smaller and without scent." This description cannot be applied to the common ivy, but corresponds exactly with those species of cistus which were most familiar to this venerable naturalist, and are both of the ladaniferous kind. It is not a little surprising that he makes no mention of the ladanum itself. Dioscorides has amply supplied the omission, and has given a particular account of its medical properties, and of the manner in which it was then collected. Bodæus a Stapel, in his notes on Theophrastus, labours hard to prove that a different position of the accent gives a different meaning to the same word; and that Κίστος with the accent on the penultimate is the proper cistus, on the last syllable the common ivy. But after much learned disquisition, he appears to us to have very honestly left the subject just as he found it, without taking away or diminishing any part of its difficulties. Dioscorides ascribes rose-coloured flowers to what was then esteemed the male, and white ones to the female; and in this he sufficiently agrees with Theophrastus, except that the latter has not noticed the colour of the flowers of the female. It appears from Dioscorides, Lib. i. cap. 126, that in his time κιστος was called by some κισθος, κισθαρον, or κιστιαρον; the last two diminutives, one of κισθος, the other of κιστος. From these variations the confusion which prevails in succeeding writers seems to have risen. Galen calls the ivy κιστος, and the true cistus κισθος. Hesychius in his lexicon does the same. *Κισθος; θαμνος δ' αρρεν και θηλυ εστιν. Κισσος; ειδος φυτυ, η βλαστημα ηλισσομενον.* The epithet ελισσομενον can be referred only to the ivy, in direct opposition to Theophrastus. Paulus Œgineta also expressly asserts that κιστος is the ivy. Pliny, the natural historian, confounds the κισσος and κιστος of the Greeks, considering both of them as species of ivy, and passing from one to the other, as if they were the same plant. See Lib. xvi. cap. 38. He begins with stating from Theophrastus, that the ivy will not grow in India, and that Alexander, on account of its rarity, and, in imitation of Bacchus, crowned his army with it, on their triumphant return from that country. He then adds, without any intimation of a transition to another subject, "Duo genera ejus prima, ut rel quarum mas et fœmina. Major traditur corpore, et folio duriori, etiam ac pinguiore, et flore ad purpuram accedente. Utriusque autem flos similis est rosæ sylvestri, nisi quod caret odore." This description is taken from Theophrastus, and can be applied only to cistus. He was doubtless deceived by the corrupt reading in the copies of that author; but it is evident that in this instance he wrote without any personal knowledge of the latter plant. He finally proceeds in the same unbroken kind of narrative, "Species horum genera tres. Est enim candida et nigra edera, tertiaque quæ vocatur helix;" and so goes on through the rest of the chapter, describing the cissus or ivy. The Arabian writers are said to have laboured under the same confusion of ideas. The earlier modern botanists partook of the embarrassment; and we cannot wonder that the disciples should be puzzled, when their revered masters were thus perplexed.

Cistus, in *Gardening*, comprehends different plants of the rock-rose, or shrubby evergreen kind; of which the species chiefly cultivated are the poplar-leaved cistus, or rock-rose (C. *populifolius*); the bay-leaved gum cistus (C. *laurefolius*); the Spanish gum-cistus (C. *ladaniferus*); the hoary rock-rose, or rose-cistus (C. *incanus*); the sea purslain-leaved cistus (C. *halimifolius*); the Montpelier gum-cistus (C. *monspeliensis*); the Cretan ladaniferous-cistus (C. *creticus*); the white-leaved cistus (C. *albidus*); the curled-leaved cistus (C. *crispus*); and the sage-leaved cistus (C. *salvifolius*). But there are others that may equally deserve cultivation. These are all plants that rise to considerable height in the stems, having a branching shrubby growth.

Of the third sort there are varieties with large white flowers, and a purple spot in the middle of the petal, and with entire white flowers. The fifth has also varieties with numerous leaves and sulphur-coloured flowers, and with yellow flowers, with purple spots in their bases. And in the sixth there is a variety with olive-shaped leaves, and sulphur coloured flowers.

Method of Culture.—All these different sorts are capable of being either raised by seeds or cuttings in the common earth, or on hot-beds; but the seed-method is mostly practised, as it produces the best plants. The seeds should be sown in the early spring season in a warm border near half an inch deep, and the plants will come up in six weeks: or, to render

der them more forward, in pots, and plunged in a moderate hot-bed. When the plants are of ſome growth, they ſhould have the full air admitted to them in the frames in mild weather, and frequent waterings, as well as occaſional ſhade from the ſun, while young; and when an inch or two high, ſome may be planted out ſeparately in ſmall pots, others in rich borders, occaſional ſhade and water being given during the ſummer-months. In autumn the potted plants ſhould be removed to a frame, to have ſhelter from froſt. Thoſe in the full ground ſhould alſo be carefully ſhielded in froſty weather with mats. In ſpring, when the weather is ſettled, thoſe remaining in the ſeed-bed ſhould be planted out, and thoſe in pots ſhifted into larger ones, to be continued another winter, and in the ſpring following be planted where they are to remain in the open ground.

When the latter method is practiſed, cuttings five or ſix inches long ſhould be planted the ſpring or ſummer ſeaſons in beds of rich earth, occaſional ſhade and water being given. When well rooted, they ſhould be removed into ſeparate pots; but by being planted in pots in the ſpring, and plunged in a hot-bed, they are rendered much forwarder. In other reſpects they require the ſame management as the ſeedling-plants.

They are all beautiful evergreen ſhrubs, effecting a fine variety at all ſeaſons, both from their leaves being of different figures, ſizes, and ſhades of green and white, and their being very profuſe in moſt elegant flowers, which, though of ſhort duration, there is a daily ſucceſſion of new ones for a month or ſix weeks on the ſame plant; and where the ſeveral different ſpecies are employed, they exhibit a conſtant bloom of near three months.

They are moſtly of a ſufficiently hardy nature to proſper in the open ground in any dry ſoil; and if they have a ſheltered ſituation, it will be an advantage, as in open expoſures they are rather ſubject to injury from very ſevere froſts; for which reaſon a plant or two of each ſort ſhould be conſtantly potted, to have ſhelter in winter in the green-houſe, or ſome other ſimilar place, where they are to be well protected in ſevere weather.

The ſecond and fifth are the moſt tender ſorts, and of courſe demand more attention.

In ſetting them out in ſhrubbery borders and clumps, they ſhould be placed towards the fronts, in aſſemblage with other choice ſhrubs of ſimilar growth. All the ſorts ſhould be ſuffered to aſſume their own natural growth, the ſtraggling branches being only cut in with a knife as there may be occaſion.

CITADEL, or CITTADEL, Fr. *Citadelle*, a diminutive of the Italian *citta*, city, and denoting little city, in *Fortification*, a kind of fort, or ſmall fortification, conſiſting of four, five, or ſix ſides, with baſtions, commonly joined to towns, and ſometimes erected on commanding eminences within them. It is diſtinguiſhed from a caſtle by its having baſtions.

When the inhabitants of any town or place in a country, particularly if it be newly conquered, are diſpoſed to revolt, citadels are built to overawe them, and prevent all attempts on their part to ſhake off their dependence, as well as to ſecure the garriſon againſt any treachery, which they might meditate, or enter into againſt them.

It frequently happens alſo, as in Italy, that when a town is large and wealthy, has but few or no fortifications; and when the fortifying of it regularly would be attended with too great an expence, a citadel is built both to ſecure it againſt the attempts of an enemy, and to ſerve as a place of ſafety for the effects of the inhabitants in time of danger.

As to the ſituation of a citadel, if a town lies in a cleared and open country, it ought to be erected on the higheſt part of the ground, in order to overlook and command all the other parts, if poſſible. If the town lies near a river or lake, that is navigable, the citadel ſhould be placed at the entrance thereof, to prevent the approach of an enemy with ſhipping. And if the place is a ſea-port, the citadel ſhould be placed near the harbour, and in ſuch a manner as to command it throughout its whole extent, both for the protection of the ſhipping in the ſame, and for the ſecurity of the town againſt a bombardment.

Due attention ſhould be paid in erecting a citadel to the placing of it in ſuch a manner, that its works may look along and ſcour the principal ſtreets of the town, in order to fire on and diſperſe the mob in caſe of any tumult, inſurrection, or ſedition, and alſo to prevent the approach of an enemy that way, ſhould the town be taken. An open ſpace, called an *eſplanade*, ſeveral hundred yards broad, ſhould be left between the works of the citadel and thoſe of the town, for the purpoſe of drawing up, muſtering, and exerciſing the troops or garriſon on, and for preventing any ſecret or hidden approach, that might be carried on from the town againſt the citadel.

Citadels may be rectangular, ſquare, pentagonal, hexagonal, or of any other figure. But the pentagonal is the form moſt commonly made uſe of. The hexagonal form is generally conſidered as too large for one, and as requiring too great an expenditure for its utility, or the advantages to be derived from it; whilſt a work of the quadrangular, or ſquare form, is regarded as too inconſiderable, and incapable of making a ſufficient defence. The citadels of Liſle, Arras, Tournay, Amiens, are pentagons; thoſe of Montpellier, Bayonne, St. Martin de Ré, Havre de Grace, and Cambray, are ſquares; that of Perpignan is hexagonal; that of Metz is nearly rectangular; thoſe of Belle Iſle and Calais are quadrangular; that of Verdun is irregularly heptagonal; that of Valenciennes is quite irregular. And ſometimes they are found in the form of a ſtar-fort.

Sometimes a citadel is erected on a hill or eminence, within the fortifications of a place. One ſo ſituated is well calculated for keeping the inhabitants in awe, if its garriſon be ſufficiently provided with neceſſaries for defending themſelves till relief can be ſent to them. But it is of little uſe againſt an enemy that once gets poſſeſſion of the town itſelf.

The exterior ſides of a citadel, when it is regular, are generally each of them about 150 toiſes, or fathoms. But they may be more or leſs at pleaſure, as occaſion or the nature of the ground requires.

The citadel ſhould be fortified in a ſtronger manner than the town itſelf, to prevent the enemy's attacking it firſt, and by means of it afterwards reducing the other. And care ſhould be taken to make the parts, where the citadel joins the town, ſufficiently ſtrong to prevent both of them from being attacked together.

There are, for the moſt part, two gates to a citadel, the one for a communication with the town, and the other with the country. The former ſerves for the garriſon of the place to retire into the citadel, in caſe of an inſurrection or ſedition, or after the town has capitulated, and the latter for receiving aſſiſtance and ſuccour, when either the town is taken, or the citadel is blockaded by the inhabitants.

The citadel generally extends along, or takes up the two ſides of the fortification of the place that adjoin it, and ſhould be conſtructed in ſuch a manner, that the ditch of the place may be defended as directly as poſſible, either by the faces of its baſtions, or by thoſe of its ravelins, and that the enemy may have no advantage wherever they commence their

their attacks; so that if they attack the citadel in the first instance, the attempt may occasion to them as much trouble and loss of time as their attacking of the town first and the citadel afterwards.

It is but seldom that a citadel is joined to a town in such a manner as to furnish a direct defence for the ditch. This is a material defect; and, when it exists, shews that the citadel is not properly joined to the works of the place. Among others that might be mentioned, the citadels of Lisle, Arras, Tournay, &c. are greatly deficient in this respect.

In addition to what has already been said respecting citadels, it may not be improper to observe, that in an extensively fortified place a citadel may be formed, by uniting parts of its works themselves, such as a couple of adjoining bastions, by a good retrenchment with flanking defences. Such a one will be sufficient for keeping the inhabitants, who may be disaffected to the government of the place, in awe, and for preventing and suppressing insurrections. And the expence of making it is very trifling, compared to that of adding another fortification to that of the place. And such additional works seldom add strength to the works of a place in proportion to the expence of erecting them.

CITADINESCA, in *Natural History*, a name given by some writers to the Florentine marble, which is supposed to represent towns, palaces, ruins, rivers, &c. These delineations are merely accidental, and are usually much assisted by the imagination, though the natural lines of a stone may sometimes luckily enough represent the ruins of some ancient building, or the course of a river. We have in England a kind of a septaria, or ludus Helmontii, which has sometimes delineations of this kind considerably beautiful, though very irregular. The Florentine marble, as we see it wrought up in the ornaments of cabinets, &c. owes a great deal to the skill of the workmen, who always pick out the proper pieces from the mass, and dispose them in the work so as to make them represent what they please.

CITAMUM, in *Ancient Geography*, a town of Asia, placed by Ptolemy in Greater Armenia, near the Euphrates.

CITERIUS, a mountain of Macedonia, according to Ptolemy. Strabo calls it *Titarus*, and says that one of its extremities touched Mount Olympus.

CITATION, formed from *cito*, of *cieo*, *I stir up*, in the *Ecclesiastical Court*, a summons to appear before an ecclesiastical judge, on some affair relating to the church.

In the civil and ordinary courts it is called *summoning*. The ecclesiastical courts proceed according to the course of the civil and canon laws, by citation, libels, &c. A person is not generally to be cited to appear out of the diocese or peculiar jurisdiction in which he lives, unless it be by the archbishop in default of the ordinary; where the ordinary is party to the suit, in cases of appeal, &c. And by law a defendant may be sued where he lives, though it be for subtracting tythes in another diocese, &c. 1 Nels. 449. By the stat. 23 Hen. VIII. c. 9. every archbishop may cite any person dwelling in any bishop's diocese within his province for heresy, &c. if the bishop or other ordinary consents; or if the bishop or ordinary, or judge, omits to do his duty in punishing the offence. Where persons are cited out of their diocese, and live out of the jurisdiction of the bishop, a prohibition or consultation may be granted; but where persons live in the diocese, if when they are cited they do not appear, they are to be excommunicated, &c. The above statute was made to maintain the jurisdiction of inferior dioceses, and if any person is cited out of the diocese, &c. where the civil or canon law doth not allow it, the party aggrieved shall have double damages. If one defame another within the peculiar of the archbishop he may be punished there; although he dwell in any remote place out of the archbishop's peculiar. Godb. 190.

CITATION is also used in speaking of military and monastic as well as ecclesiastical courts. Such a heretic was cited to Rome, to a general council, &c.

Knights are cited to the general chapters of their order. King Edward I. of England was cited by order of Philip IV. of France, to a court of his peers; the citation was published by the seigneur d'Arrablay, seneschal of Perigord and Querci; and was pasted up by his order, on the gates of the city of Libourne, which then belonged to king Edward. And for default in not appearing, all his domains and effects in France were confiscated.

CITATION is also an allegation or quotation of some law, authority, or passage.

CITELLUS, or CITILLUS, in *Zoology*, the name of a small quadruped of the marmot tribe, the *arctomys citillus* of Schreber and Gmelin, and *mus citillus* of Pallas. Citillus is the old name under which Ray and Gesner describe this little animal; Buffon calls it *le zizel* and *le souslik*; Güldenstadt, *mus suslica*; and Pennant, the *casan* or *earless marmot*.

The earless marmot, as its trivial appellation implies, is specifically distinguished from the rest of the *arctomys* genus by being destitute of ears, the tail is villous, and body variegated. The prevailing colour is brown spotted, or otherwise diversified with white; the under parts white, inclining to yellowish, the tail is of a brown colour above and ferruginous beneath. The length is about ten inches and a half including the tail, the body only, from the tip of the nose to the base of the tail, measuring six inches. According to Pallas this animal varies, however, considerably in size as well as colour, for he assures us there are some varieties scarcely larger than the common water-rat, while others are nearly equal in size to the alpine marmot. The earless marmot is an inhabitant of several parts of Europe, being found in Bohemia, Austria, and Hungary, the southern part of Russia, from the banks of the Volga to India and Persia; through Siberia and Great Tartary to Kamtschatka; it occurs also in China and America.

The writings of Pallas afford us an interesting history of the manners of this little animal. He observes that it delights in dry hilly places, where the herbage is of short growth, although it is sometimes found in woods; they form subterraneous burrows in which they deposit their winter food, which consists chiefly of grain, roots, or nuts, for they do not appear to sleep during the winter season like some others of this genus. They breed in the spring, and produce from five to eight at a litter; they are sometimes seen in considerable numbers basking in the sun-shine near the entrances of their burrows, and when disturbed utter the same kind of shrill whistle as the common marmot. In a state of nature they are quarrelsome and ferocious among themselves, though they may be more readily tamed than most other animals. Vegetables are their principal food, but they also prey on small birds and animals. They are of an extremely cleanly disposition, and after feeding wash their faces and lick their fur after the manner of cats. Like other domesticated animals, they are fond of being caressed and feed readily from the hand; their sleep, according to Pallas, is extremely profound; it commences early in the evening and continues during the whole night, and even during great part of the day, when the weather happens to be cold or rainy.

Gmelin expresses some doubts whether this may not be the *mus ponticus* of Aristotle and Pliny. Some other late writers conceive that the *zizel* and the *suslic* of Buffon are

 distinct,

diſtinct, and that of conſequence the hiſtory of two different animals has been erroneouſly confounded by thoſe who conſider them as varieties only of a ſingle ſpecies.

CITERIA, ſmall figures which were made to ſpeak like our puppets, and which were carried before a Roman general on the day of his triumph. Theſe puppets uttered every kind of ludicrous words to excite the laughter of the people at the expence of the captives.

CITHÆRON, in *Ancient Geography*, a mountain of Greece in Bœotia, near the city of Thebes. Pliny and Mela ſay that it was conſecrated to the Muſes; and Plutarch ſays, that it was called "Arterius," before it was named Cithæron.

CITHARA, in *Ancient Muſic*, a ſtringed inſtrument, of the harp or lute kind. The idea of producing ſound from a ſtring, aſcribed to Apollo, was, according to Cenſorinus, *De Die Nat.* cap. 22. ſuggeſted to him by the twang of his ſiſter Diana's bow. Ψαλλειν is ſtrictly to twang a ſtring, and Ψαλμος the ſound which the bow-ſtring produces at the emiſſion of the arrow. Euripides in Bacch. v. 782, uſes it in that ſenſe,

——————— ——————— τοξων χερι
Ψαλλουσι νευρας.

Who twang the nerve of each elaſtic bow.

Father Montfaucon ſays it is very difficult to determine in what the lyre, cithara, chelys, pſaltery, and harp, differed from each other; as he had examined the repreſentations of 600 lyres and citharas in ancient ſculpture, all which he found without a neck, and the ſtrings open as in the modern harp, played by the fingers. Antiq. Expl. tom. iii. lib. 5. cap. 3. But though ancient and modern authors uſually confound theſe inſtruments, yet a manifeſt diſtinction is made by Ariſt. Quintil. in the following paſſage, p. 101. After diſcuſſing the characters of wind-inſtruments, he ſays, "Among the ſtringed inſtruments, you will find the lyre of a character analogous to *maſculine*, from the great depth or gravity, and roughneſs of its tones; the *ſambuca* of a *feminine* character, *weak* and *delicate*, and from its great *acuteneſs*, and the ſmallneſs of its *ſtrings*, tending to *diſſolve* and *enervate*. Of the intermediate inſtruments, the *polypthongum partakes* moſt of the *feminine*; but the *cithara differs not much* from the *maſculine character* of the *lyre*." Here is a ſcale of ſtringed inſtruments; the *lyre* and *ſambuca* at the extremes; the *polypthongum* and *cithara* between; the one next to the *ſambuca*, the other next to the *lyre*. He afterwards juſt mentions that there were others between theſe. Now it is natural to infer, that as he conſtantly attributes the manly character to gravity of tone, the cithara was probably the more acute inſtrument of the two; leſs loud and *rough*, and ſtrung with ſmaller ſtrings. Concerning what difference there might be in the form and ſtructure of the inſtruments, he is wholly ſilent. The paſſage, however, is curious as far as it goes, and deciſive. The cithara may perhaps have been as different from the lyre, as a ſingle harp from one that is double; and it ſeems to be clearly pointed out by this multiplicity of names that the Greeks had *two* principal ſpecies of ſtringed inſtruments: one, like our harp, of full compaſs, that reſted on its baſe; the other more portable, and ſlung over the ſhoulder, like our ſmaller harp or guitar, or like the ancient lyres repreſented in ſculpture.

Tacitus, Annal. xvi. 4. among the rules of decorum obſerved by public performers, to which Nero, he ſays, ſtrictly ſubmitted, mentions, "That he was not to ſit down when tired." *Ne feſſus reſideret*. It is remarkable that he calls theſe rules, *citharæ leges*, "the laws of the cithara;" which ſeems to afford a pretty fair proof of its being of ſuch a ſize and form as to admit of being played on *ſtanding*.

The uſe of the *phorminx* in Homer leads rather to the rough, manly, harp-like character. But a paſſage in Orpheus (Argon 381.) ſeems to make *phorminx* the ſame as *chelys*, the lutiform inſtrument of Mercury. It is there ſaid of Chiron, that he "ſometimes ſtrikes the cithara of Apollo; ſometimes the *ſhell-reſounding phorminx* of Mercury,"

Αλλοτε δ' αυ Φοιβου κιθαρην μετα χερσιν αρασσων,
Ηλιγυεσσαν φορμιγγα χελυκλονον Ερμαωνος.

This paſſage is curious; for though the Argonautics were not written by Orpheus himſelf, they have all the appearance of great antiquity.

The belly of a theorbo, or arch-lute, is uſually made in the ſhell-form, as if the idea of its origin had never been loſt; and the etymology of the word guitar ſeems naturally deducible from cithara; it is ſuppoſed that the Roman C was hard, like the modern K, and the Italian word *chitarra* is manifeſtly derived from κιθαρα, *cithara*.

In the hymn to Mercury, aſcribed to Homer, Mercury and Apollo are ſaid to play with the cithara *under their arms*, ver. 507. ὁ δ' ὑπωλενιον κιθαριζεν, *ſub ulna Citharâ ludebat*, "played with the Cithara *under his arm*." So in ver. 432. επωλενιον, at his arm, ſhould, according to the critics, be ὑπωλενιον, as it is afterwards. This ſeems to point out a guitar more than a harp; but the ancients had lyres, citharas, and teſtudos of as different ſhapes from each other, as our harp, ſpinet, virginal, and piano-forte.

Theſe paſſages in old authors are a kind of antique drawings, far more ſatisfactory than thoſe of ancient ſculpture; for we have ſeen the ſyrinx, which had a regular ſeries of notes aſcending or deſcending, repreſented with ſeven pipes, four of one length, and three of another, which of courſe would furniſh no more than two different ſounds. The cymbals too, which were to be ſtruck againſt each other, are placed in the hands of ſome antique figures in ſuch a manner, that it is impoſſible to bring them in contact with the neceſſary degree of force, without amputating, or at leaſt violently bruiſing the thumbs of the performer. And it is certain that artiſts continue to figure inſtruments in the moſt ſimple and convenient form for their deſigns, long after they had been enlarged, improved, and rendered more complicated. An inſtance of this in our own country will confirm the aſſertion. In the reign of George the Second a marble ſtatue was erected to Handel, in Vauxhall gardens. The muſician is repreſented playing upon a lyre. Now if this ſtatue ſhould be preſerved from the ravages of time and accident 12 or 1400 years, the antiquarians will naturally conclude that the inſtrument upon which Handel acquired his reputation was the lyre; though we are at preſent certain that he never played on, or even ſaw a lyre, except in wood or ſtone.

In one of the ancient paintings at Portici, we ſaw a lyre with a pipe or flute for the croſs-bar, or bridge, at the top; whether this tube was uſed as a wind inſtrument to accompany the lyre, or only a pitch-pipe, we know not; nor, within the courſe of our inquiries, has any example of ſuch a junction occurred elſewhere.

CITHARÆDIST, a performer on the cithara or lute.

CITHAREXYLUM, in *Botany*, (from κιθαρα, a *harp*, and ξυλον, *wood*) fiddle-wood. Fr. Guittaren, or Bois de Guittarre, Cotelet. Enc. Linn. gen. 760. Schreb. 1019. Willd. 1158. Gært. 339. Juſſ. 108. Vent. vol. ii. 320. Lam. Ill. Pl. 545. Claſs and order, *didynamia angioſpermia*.

Gen. Ch. *Cal.* Perianth one-leafed, campanulate, fhort, toothed or truncated, permanent. *Cor.* one-petalled, funnel-fhaped; tube longer than the calyx; border wheel-fhaped, five-cleft; fegments oblong, villous on the upper furface, almoft equal. *Stam.* Filaments four in moft fpecies, with the rudiment of a fifth from the middle of the tube, fhorter than the tube, two of them fomewhat longer than the others; anthers oblong, didymous, erect. *Pift.* Germ fuperior, roundifh; ftyle filiform, the length of the ftamens; ftigma with an obtufe head. *Peric.* Drupe roundifh, flightly compreffed, one-celled, containing two nuts, each nut two-celled, egg-fhaped, hard, plano-convex, with an obfolete furrow on the back. *Seeds,* one in each cell of the nut, but in one of the cells fometimes abortive.

Eff. Ch. Calyx toothed or truncate. Corolla funnel-wheel-fhaped; fegments villous above, nearly equal. Drupe with two nuts; nuts two-celled.

Sp. 1. C. *cinereum*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Brown. Jam. 264. Pluk. Alm. tab. 162. fig. 1. (C. teres, Jacq. Amer. tab. 118. Pict. tab. 178. Jafminum arborefcens racemofum foliis lauri, Plum. MSS. Burm. Amer. tab. 157. fig. 2.) " Branches cylindrical; calyxes toothed," Linn. " Branches cylindrical; leaves oblong, acuminate, quite entire; racemes pendulous; calyxes toothed." A tree from fifteen to twenty feet high, not more than a foot in diameter, with a handfome branched head. *Branches* cinereous, fmooth. *Leaves* commonly oppofite, oblong-oval, acuminate at both ends, entire, bright green, and fhining on the upper furface, a little veined underneath, with a few hairs on the axils of the nerves; petioles yellowifh, with two or three concave mellifluous glands near their infertion into the leaf. *Flowers* white, numerous, fmall, fweet-fcented, on fhort peduncles, racemed; racemes from feven to nine inches long, quite fimple, terminal, pendulous, folitary, or accompanied by two or three fmaller ones at the bafe; corollas bearded at the mouth. *Fruit* roundifh, fucculent, fhining, foft, firft green, then red, finally black. Jacq. and La Marck. According to the latter, the branches in the plants cultivated at Paris are not cylindrical, as Linnæus defcribes them, but truly tetragonal. A native of Jamaica, where it is called Old woman's bitter; and of Martinico and St. Domingo, where it is called by the French Bois Cotelet. 2. C. *quadrangulare*, Mur. Syft. 564. Jac. Amer. 186. Hort. tab. 22. (C. cinereum β Lam.) It appears to be only a variety of the laft fpecies, as La Marck confiders it, differing chiefly in having the berries red, or lefs black when ripe. The branches are round, but made apparently quadrangular, by having four ribs running down them. 3. C. *caudatum,* Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 2.? Brown. Jam. 265. tab. 28. fig. 2. Swartz. Prod. 234. " Branches cylindrical; calyxes truncate," Linn. A fhrub ten or twelve feet high. *Leaves* inverfely egg-fhaped, lefs acuminate than thofe of C. cinereus. *Racemes* terminal. *Fruit* fmall. A native of Jamaica. Willdenow gives the caudatum of Swartz, as a fynonym of quadrangulare; but as Swartz's plant has truncate calyxes, we apprehend there can be no doubt of its being the caudatum of Linnæus, and the plant defcribed by Browne, which is exprefsly ftated to have truncated calyxes. The C. erectum of Swartz, Prod. 91. Jacq. Ic. Rar. 3. tab. 501. quoted by Willdenow as a fynonym of caudatum, appears to us a diftinct fpecies, with toothed calyxes. 4. C. *villofum*, Mart. 4. Willd. 3. Jacq. Ic. Rar. tab. 118. Collect. 1. p. 72. Hort. Kew. 2. 349. " Branches tetragonal; leaves inverfely egg-fhaped, pubefcent underneath, fomewhat toothed at the tip; racemes nodding." A fmall tree, about ten feet high. *Trunk* and older branches round and cinereous; younger branches quadrangular and green; young fhoots villous. *Leaves* three inches long, oppofite, on fhort petioles, acute, firm, fomewhat rugged on the upper furface, extremely foft and villous on the under, with an oblong deep-green glandular hole on each fide of the petiole at the top. *Flowers* white, numerous, on fhort peduncles, villous all over, fweet-fcented; racemes half a foot long, terminal, pendulous; calyx truncate; according to Willdenow, obfoletely toothed, fo as to be almoft truncate; but in this as well as in his fpecific character of C. caudatum, he feems biaffed by a refolution to have a five-toothed calyx part of the effential character of the genus. A native of St. Domingo. 5. C. *fubferratum*, Willd. 4. Swartz Ind. Occ. 2, p. 1043. Prod. 91. " Branches tetragonous; leaves oblong, rigid, tranfparent at the tip, fomewhat ferrated; racemes rather erect, calyxes toothed." *Leaves* veined. *Racemes* terminal, panicled. A native of Hifpaniola. 6. C. *melanocardium*, Mart. 5. Willd. 6. Swartz. Prod. 91. Flor. Ind. Occ. 2. p. 1046. Brown. Jam. 265. (C. paniculatum, Gært. tab. 56.) " Branches tetragonous; flowers panicled, tetrandrous; leaves fomewhat wrinkled, veined underneath, a little fcabrous." A tree forty or fifty feet high, producing hard excellent timber; bark thick, whitifh, winding, like the fibres of the wood, in a loofe fpiral form. *Leaves* rather long, flightly ferrated. *Flowers* in terminal panicled racemes, tetrandrous, and, as we prefume, without the rudiment of a fifth ftamen. *Drupes* fmall, yellow, egg-fhaped, black, fmooth. *Seeds* oblong, a little quadrangular, reddifh. A native of Jamaica.

Propagation and Culture. The fecond and fourth fpecies are cultivated in England; and as they do not produce feeds in this climate, they are chiefly propagated by cuttings; but when feeds can be procured from the Weft Indies, the plants which proceed from them are much better. They require the fame kind of treatment as other tropical plants.

CITHARISTA, Ceireste, in *Ancient Geography*, a town of Gallia Narbonnenfis, at fome diftance from the fea, in the fame gulf with " Tauroentum," about ½ of a mile from each other. Veftiges of edifices erected by the Romans are ftill vifible.

Citharista *Portus*, a harbour of Gallia Narbonnenfis, now called the port of " Ceirefte."

CITHARISTES Promontorium, *Cape Lician*, a promontory belonging to Gaul, between Tauroentum and Obbia.

CITHARISTIC, in *Ancient Mufic*, mufic and poetry fitted to the accompaniment of the cithara.

CITHARIZUM, in *Ancient Geography*, a fortrefs of Afia, in Aftianena, a country of Greater Armenia.

CITHAROEDUS, in *Antiquity*, the fame with citharifta. The citharoedi had the preference of all other muficians, from whom they were diftinguifhed by an embroidered cloak, which was peculiar to them.

CITHENI Juga, in *Ancient Geography*, a name given by Pliny to mountains of Afia, which he places in Parthia, near the country called *Choara.*

CITHIBEB, in *Geography*, a town of Africa, in the kingdom of Morocco, and province of Tedla.

CITHRUM, in *Ancient Geography*, a town of Greece, in Theffaly.

CITILLUS. See Citellus.

CITIUM, Chiti, in *Ancient Geography*, a town on the fouthern coaft of the ifland of Cyprus, near the river Tetius, N.E. of Amathus. Jofephus fays, that this city was built by Cittim, the fon of Javan, and from him was called Citium, or, as Pliny has it, Cetium. It was the birth-place of Zeno the Stoic; and the place where Cimon the Athenian died, after having reduced great part of the ifland. Citium was epifcopal.—Alfo, the name of an ancient town of Macedonia.

CITIUS, a name given by Livy to a mountain of Greece, which was fituated towards Ætolia.

CITIZEN, or Cittizen, a native or inhabitant of a city, vefted with the freedom and rights thereof.

The word comes from *civis*, which authors derive from *ceo*, becaufe the citizens live together; or rather from *cieo*, *I call together*.

Auguftus, upon numbering the Roman citizens, found they amounted to upwards of four millions.

To make a good Roman citizen, there were three things required: that he was an inhabitant of Rome; that he were inrolled in one of the thirty-five tribes; and that he were capable of dignities. Thofe ftrangers to whom were granted the rights and privileges of Roman citizens, were properly only honorary citizens. By the Porcian law it was ordained, that no citizen of Rome fhould be put to death. It was alfo a privilege of the utmoft confequence to a Roman citizen, to have none but the people for his judges. Were it not for this, he would have been fubject in the provinces to the arbitrary power of a proconful, or of a proprætor.

The feventh law, *de incolis*, makes a great deal of difference between a citizen and a mere inhabitant. Birth alone made a citizen, and intitled to all the privileges of burgeffes; time could not acquire it, but the emperor could beftow it; and it was often given to men and cities as a reward of fome fpecial merit or fervices. It is not improbable that the citizenfhip of St. Paul, mentioned in the book of Acts (ch. xxi. 37. 39), was of this kind, fome of his anceftors having obtained it for fervices they had done to the Roman commonwealth in the wars. (See Grotius ad Acts xxii. 28.) This privilege was alfo bought, and that at a very great price, as Dio Caffius informs us (l. lx.). "The Romans," he fays, "having the preference above ftrangers, there were many who begged the citizenfhip of the emperor, and others who bought it of Meffalina, or the freed-men. By which means this privilege, which had been formerly bought at a great price, became fo cheap, that many people would fay, a man might be made a Roman citizen for a few pieces of broken glafs," υαλινα σκευη συντετριμμενα.

The Romans were anciently fo particularly careful to preferve even their common citizens from any mixture of fervile blood, that they prohibited all marriages between them and freed flaves, or their children. And it was decreed, as a fpecial privilege and reward to one Hifpala, of libertine condition, for her difcovery of the impieties of the Bacchanalian myfteries, that a citizen might take her to wife without any difgrace and diminution of his rights. Thefe diftinctions, indeed, began to be difregarded towards the end of the republic, with refpect to the ordinary citizens, but were kept up to the laft with regard to the fenate. See Senator.

In order to have a right to the title of citizen by birth at Athens, it was fufficient to be born of a father and mother who were both citizens; but the child of an Athenian, who married a foreign woman, was entitled only to the condition of his mother. This law was made by Pericles, and he executed it with fo much rigour, that nearly 5000 perfons, excluded from the rank of citizens, were publicly fold by auction. At firft, when it was neceffary to encourage the population of Attica, the title of citizen was beftowed on every perfon who came to fettle in that country. When that neceffity ceafed, Solon granted it only to thofe who fhould bring with them their families, or to perfons who, exiled for ever from their country, came thither in fearch of a fecure afylum. At length it was permitted to thofe who fhould render fervices to the ftate. This honour was ardently fought even by fovereigns, as long as the Athenians rigoroufly obferved the laws to prevent its being too eafily obtained; afterwards it was held in lefs eftimation. According to Ariftotle, the privilege of citizen ought to be granted only to him, who, free from every other care, dedicates himfelf entirely to the fervice of his country; and hence it would follow, that the name of citizen is imperfectly applicable to children and decrepit old men, and cannot appertain to artifans, labourers, and freedmen. Among the advantages which eftablifh or deftroy the equality of citizens, Ariftotle mentions three which merit fome confideration; liberty, virtue, and riches. In all governments, he fays, individual citizens are and ought to be in fubjection; and liberty, he adds, does not confift in doing whatever we pleafe, as is maintained in certain democracies, but in only doing what is enjoined by the laws, which fecure the independence of each individual; and in this point of view all the citizens may enjoy equal liberty. As our citizens, he fays, participate in the fovereign authority, they fhould be all equally interefted to maintain it, and deeply imbibe the fame love for their country; and they will be more or lefs free, in proportion as they are more or lefs virtuous. With refpect to riches, he obferves, that ancient legiflators judged it neceffary, in the commencement of a reformation, to divide property equally among all the citizens; but he maintains that a difference in riches may have place among citizens; but as this difference can occafion none in the diftribution of employments and honours, it will not deftroy that equality which ought to fubfift among them. They fhall be equal, becaufe they fhall only be fubject to the laws; and they fhall be all equally occupied in the glorious employment of contributing to the tranquillity and happinefs of their country. Arift. de Republ. lib. 2, 3, 4, 5.

Citizens *in Parliament*. See Burgesses.

Citizens *of London*. See London.

CITOIS, Citesius, Francis, in *Biography*, a learned and ingenious phyfician of Poitiers in France. He ftudied medicine at Montpellier, where he took his degree of doctor in 1596; after practifing a few years in his native city he went to Paris, and was foon placed at the head of the profeffion, being in high repute with cardinal Richlieu, and made his phyfician. He diftinguifhed himfelf, among other things, for his treatment of the Colica Pictonum, on which he wrote a treatife, containing a portion of practical knowledge, much fuperior to the ufual productions of that age. "De Novo, apud Pictones, Dolore Colico Biliofo," 1616, 8vo. It paffed through feveral editions. He thought the difeafe either appeared for the firft time in the year 1572, or was attended with fymptoms not noticed before; particularly with paralyfis of the extremities. He wrote an account of a girl, twelve years of age, who, after a fit of ficknefs, by which fhe had been much reduced, loft the inclination and the power of taking fuftenance of any kind; fhe had lived in this ftate three years, when Citois publifhed his account. As the ftory was incredible, it was not without opponents, which produced from Citois, "Abftinentia Puellæ Confolantaneæ ab Ifraelis Harveti Confutatione Vindicata," 1602, 8vo. It was the next year tranflated into Englifh, and publifhed in London. Citois, to fhew his perfect belief of the fact, added to this edition ftories of long abftinence both in men and beafts. It appeared however to have been a fraud, for the girl being removed from the care of her mother, took milk, and afterwards broths and then folid aliments. "De tempeftivo Phlebotomiæ ac Purgationis

tionis usu, adversus Homophobos, in collectione Opusculorum," Paris, 1639, 4to. He defends the use of bleeding in the small-pox, measles, and in fevers of an inflammatory type; he ordered the operation to be repeated six or seven times. He died at Poitiers, to which place he had retired in 1652, being 80 years of age. Haller, Bib. Eloy. Dict. Hist.

CITOLE, an old musical instrument, mentioned by Gower, supposed to be derived from *cistella*, a small chest, probably a kind of dulcimer.

CITOW, in *Geography*, a town of Bohemia, in the circle of Schlan; 10 miles S.E. of Raudnitz.

CITRARO, a town of Naples, in the province of Calabria Citra, near the coast of the Tuscan sea; 18 miles W. of Bisignano.

CITREÆ MENSÆ, called *thyina* by the Greeks, in *Antiquity*, tables made of the wood of the citrum-tree, very beautiful, and greatly esteemed by the ancient Romans. See CITRUM.

CITRIC ACID, *Acid of Lemons*, *Zitronensaure*, Germ. Lemon juice is one of the sourest and most agreeable of all the vegetable acids. It is procured simply by squeezing the fruit and straining the juice through linen or any loose filter. This juice forms a considerable article of commerce in Sicily, Italy, Majorca, and other parts of the Mediterranean. It is obtained by peeling the fruit, slicing it, and putting it in a strong press with a cloth or hair strainer. The juice, which comes out very turbid, is then placed for a day in a cool cellar and then strained into jars with very narrow necks, which are then well cemented up. A little oil is often previously poured on the juice to keep it more completely from the air. These presses are sometimes so large as to squeeze six thousand lemons at once.

Lemon juice is a fluid of about the specific gravity of 1.034, and therefore heavier than water, composed chiefly of water, which holds in solution vegetable mucilage, extractive matter possessed of some astringency, a little malic acid, and lastly that peculiar acid which, from its being contained more copiously in this fruit than in any other, is called the citric acid. The proportion of these ingredients of course must vary as in all native vegetable juices, but on an average (according to professor Proust), 576 grains of the fresh juice lose by evaporation 528 grains, which is the watery part; of the remaining 48 grains about 30 are the pure citric acid, and the rest is malic acid, mucilage, and extract. It is to the presence of these two latter ingredients that we may attribute the change that takes place in the juice by keeping, by which it becomes mouldy, undergoes an imperfect fermentation, and, at last, totally loses its acidity, and acquires a flat musty taste.

To prevent this destruction of the acid, for which alone lemon juice is valuable, many methods of preserving the juice have been devised, all of which answer to a certain degree, but none of them completely; and the only way of keeping the acid for a great length of time is first to extract it from the juice in the way which will be presently described, and to bring it to a solid state of crystallization.

Lemon juice is clarified partly by remaining perfectly at rest in a cold cellar for a day or two. Much of the mucilage then subsides, together with any accidental mixture of the pulp of the fruit, and the juice poured off clear, bottled, and carefully corked, will then keep for a considerable time. It keeps better if boiled briskly for a minute or two before it is set by to clarify, but this somewhat impairs the flavour, and gives another which is less agreeable. In the Mediterranean countries the juice is covered with oil, which, by preventing the action of the air, assists in preserving it; but after a while the juice beneath becomes bitter, mouldy, and turbid, and besides acquires from the oil a rank flavour.

Concentration of the juice by freezing is another method which is sometimes used with considerable success. If the mucilage is first separated as much as possible by standing in a *cool* place for a day or two, and the clear juice is then exposed to a cold of from 23° to 26° Fahr.; the watery part alone freezes, and the remaining unfrozen liquor of course contains the acid in a proportionably condensed state. By continuing to remove the ice as it forms as long as it remains tasteless, when the adhering liquor is washed off, lemon-juice may be concentrated to about one eighth of its original bulk, and is then clear, intensely sour, and will keep for some years unaltered in a cool climate. Still, however, much extract and some mucilage remain in it, and therefore in tropical climates even this concentrated juice spoils in no very great length of time. Besides, the process itself is only adapted for the winter season, and in hot climates the juice would generally be spoiled before a sufficient cold for this purpose would occur.

Another mode of preserving this juice, often adopted, is, to make certain additions to it, which lessen the tendency to fermentation. Forster found, during Cook's voyage to the south pole, that the juice, mixed with a fifth part of brandy or rum, and put in very well-closed casks, kept good for thirty-two months. Bragnatelli proposes to clarify the fresh juice by alcohol. Fresh lemon juice was mixed with some strong alcohol and bottled; in a few days a slimy mucilage had subsided, and the liquor after filtration contained the purer juice and the alcohol. This last may be recovered by distillation. But it is obvious that this is only a very imperfect clarification, since this liquor, on evaporation to dryness, yields only a sour gummy extract, and no crystallized acid. Some persons are in the habit of adding sulphuric, or some other mineral acid to the juice, partly to preserve and partly to adulterate it. This does, indeed, preserve the juice for a considerable time; but unless the purchaser can depend on the quantity of addition made, he might be exposed to serious loss and inconvenience, particularly when the juice is used in calico-printing, as will be presently mentioned, along with the method of discovering such adulteration.

A further method of preserving the juice, which is certainly the best for hot climates, and can often be performed in the large way at a moderate expence, is, by evaporating it considerably, and thus concentrating the acid in a smaller compass. The citric acid is less volatile than water, and indeed cannot be made to rise at all in distillation, like vinegar, without suffering considerable decomposition, and an actual and great loss of the acid. Hence when the fresh juice, previously clarified by rest, is exposed to a gentle heat, never exceeding the boiling point of water, most of the mere water which it contains flies off, and the juice may safely be inspissated to the consistence of thick syrup, without much loss of the acid, care being taken to avoid burning it. It is then intensely sour, and will keep in bottles for many years without alteration, and even retaining much of its original flavour. This inspissated juice, or *rob of lemons*, as it is called, if intended for the table, may be immediately mixed with dry white sugar, which is one of the best preservers from corruption, and it will then keep in closed bottles for any length of time unimpaired, and forms an excellent and extemporaneous lemonade, by the addition simply of water, which is a very valuable store for sea-voyages.

In very hot countries this inspissation may be begun and carried

carried on to a confiderable degree by the mere heat of the fun.

But the pure *citric acid* cannot be obtained by any fimple infpiffation, for its adhefion to the mucilage or extract of the juice is fo ftrong, that, however well it be previoufly clarified, the acid will never cryftallize by mere evaporation, but only feparates in a four gummy mafs when all the water is diffipated. To procure the pure cryftallized acid, a double procefs of chemical affinity is required; firft, to add fome earthy fubftance with which the acid alone unites, and forms an infoluble falt, to the exclufion of the extract or mucilage; and next, to difplace this acid from the earthy falt by means of another acid of ftronger affinity to the earth than the citric, and then this latter acid may be obtained pure by due evaporation of the fupernatant liquor, and cryftallizing. This very ingenious procefs was difcovered by Scheele, and has been fince followed, with flight variations, by every fucceeding chemift. The earth which this admirable chemift employed was lime, in the form of chalk, the fame that he had before ufed in the preparation of the concrete acid of tartar.

The procefs given by Scheele is, in a few words, the following: Saturate boiling lemon juice with chalk in powder added gradually, till all effervefcence ceafes. A grey infoluble mafs fettles to the bottom, compofed of the citric acid united with the lime, leaving the mucilage and other ingredients of the lemon juice in the fupernatant liquor, which may be thrown away, and the citrat of lime is to be well wafhed with *cold* water till the latter comes away colourlefs. Then, add to the precipitate a quantity of fulphuric acid, equal to the weight of chalk employed, but previoufly diluted with about ten parts of water. Boil the whole for a few minutes, and a change of compofition takes place, the fulphuric acid engaging the lime, and the citric acid paffing into the fupernatant liquor. Strain off the latter, and evaporate it flowly to the confiftence of a thick fyrup, and by ftanding for fome days, moft of the citric acid will feparate in large cryftals. A fmall excefs of fulphuric acid is requifite to enable the citric acid to cryftallize, which otherwife would only concrete into a gelatinous mafs.

Such is the procefs of this excellent chemift, to which he adds feveral valuable obfervations, which will prefently be mentioned; but as the preparation of this acid is now become of confiderable importance, it will be proper to compare the feveral proceffes and improvements propofed by other chemifts, particularly by Dizé (fee "Journal des Phyfique,"); by Weftrumb (fee Leonhardi in Macquer Worterbuch, art. Citronenfaure); by profeffor Prouft (fee Journ. de Phyf.); by Richter (Gren's Handbuch), and others.

In preparing the citric acid in the great way, M. Dizé gives the following particulars: After the citrat of lime has been decompofed by the fulphuric acid, *cold* water, affifted by ftirring, is fufficient to wafh out all the citric acid adhering to the fulphat of lime, which fhould therefore be employed, and thefe wafhings added to the filtered liquor. Much fulphat of lime, however, remains in the clear liquor, which, in fact, is a mixture of citric acid, fulphuric acid, and fulphat of lime, and is of a clear light yellow. It may be evaporated at a boiling heat, and as the bulk of fluid leffens, the fulphat of lime falls down, fo that it is of ufe to fufpend the evaporation once or twice for fome hours, to give time for the fulphat of lime to feparate, which fhould be removed. Towards the end of the evaporation the liquor becomes blackifh, owing to the fulphuric acid remaining in it, becoming fo concentrated as to act partly on the acid itfelf, and partly, as this chemift fuppofes, on a portion of the original extractive matter which accompanies the citric acid, in its combination with lime, and feparation from it, and which appears to be the caufe of the difficulty found in getting the whole of the acid to cryftallize. This acid is fo very foluble that the evaporation muft be pufhed to a very thick fyrupy confiftence before it will cryftallize. The cryftals are at firft black and dirty; by a fecond folution in cold water, of which a fmall quantity will fuffice, filtration, and evaporation, the cryftals are obtained yellow and more regular; but a third operation of the kind feems neceffary to bring them to be perfectly tranfparent and colourlefs. As there is much wafte in thefe operations, all the wafhings and fouled parts fhould be referved for fubfequent purification.

Scheele remarked, (and other chemifts have found the fame,) that an excefs of fulphuric acid, beyond what the lime requires for faturation, is neceffary in this procefs. M. Dizé fuppofes the peculiar ufe of this excefs of acid to be that of deftroying the fmall portion of extractive matter that remains in the calcareous compound; the exiftence of which he endeavours to prove, by the proportions of ingredients required, compared with their products. He found 100 lbs. of lemon juice to require for faturation 6.25 lbs. of chalk, and to produce as much as 20 lbs. of citrat of lime. On the other hand, he found the cryftallized citric acid to require its own weight of chalk for faturation, and to produce a quantity of citrat of lime equal to three-fourths of the weight of the two ingredients, the lofs being chiefly carbonic acid. Hence he concludes that 100 lbs of frefh juice contain 6.25 lbs. of the pure acid (being equal in weight to the chalk required), and that the citrat of lime, thence refulting, ought, if pure, to be no more than 9.378 lbs. being three-fourths of the fum of the weight of the chalk, and the eftimated quantity of pure acid. But as he finds it to be really 20 lbs., even after wafhing, he fuppofes this great difference to be made up by extractive matter precipitated along with the citrat of lime, and adhering to it.

However, the experiments of other chemifts do not give this difference, though they agree tolerably well in other particulars. M. Dizé does not fpecify the quantity of cryftallized acid actually obtained from a given quantity of juice.

Weftrumb faturated 4 lbs. of ftrained lemon juice with 3 oz. of chalk, and obtained 5 oz. and 1 dram of citrat of lime, which, decompofed by 23 drams of ftrong fulphuric acid, diluted with ten times its bulk of water, gave, by due evaporation, $2\frac{1}{2}$ oz. of cryftallized acid, and a little foul, which loft one dram by a fecond cryftallization.

Profeffor Prouft has examined the fame procefs, with attention to the actual quantities employed and obtained. The whole of the above experiments may be given in the following tabular form:

Lemon Juice.		Chalk.		Citrat of Lime.		Citric Acid.		Citric Acid.	
100 lbs.	require	4.25 lbs.	which	7.51 lbs.	yield	4.38 lbs.	and contains	4.74 lbs.	Prouft.
——	for	4.65	produce	8.0	by	3.90	by	——	Weftrumb.
——	faturation	6.25		20.0	evaporation	——	eftimation	6.25	Dizé.
Cryftal. Citric A.									
6.25	-	6.25	- -	9.375					Ditto.

With

With regard to the proportions given by Prouft, it is to be obferved, that only 7.51 lbs. of citrat of lime were actually precipitated; but by evaporation of the liquor he obtained about .54 lb. additional. The cryftallized acid was obtained from a known quantity of the wafhed citrat of lime, fix ounces of the latter giving $3\frac{1}{2}$ oz. of the acid, and hence 7.51 lbs. would yield 4.38 lbs., to which the additional .54 lb. of citrat would add .315 lb.; and a fmall portion of acid is alfo left in the laft liquor after all the cryftals have been removed, which the author eftimates at about $\frac{1}{100}$th of the quantity obtained, or about .049 lb., which together make a total of 4.74 of folid acid in 100 lbs. of the frefh juice.

The quantity of fulphuric acid required for the decompofition of the citrat is varioufly eftimated, but it fhould not be lefs of the concentrated acid than a weight equal to the chalk employed, of which latter rather more fhould be ufed than will faturate the juice. If a portion of the fame chalk is feparately faturated with the *diluted* fulphuric acid intended to be employed, and the refpective quantities noted, it will be a ftill better guide for the quantity of fulphuric acid to be ufed in the fecond decompofition, obferving always that a fmall *excefs* of this acid is required. The clear liquor which ftands above the citrat of lime in the firft procefs contains, befides the mucilage and extract, a portion of *malat of lime* in folution, which may be precipitated by alcohol if the liquor is reduced by evaporation. A fmall portion of gallic acid alfo appears in lemon juice, as it turns of a brown red on the addition of a folution of iron, and exactly faturating the liquor with an alkali.

To feparate the citric acid completely from the citrat of lime by the fulphuric acid, it is better to boil the whole for about ten minutes. The difficulty of feparating all the fulphat of lime and extract from the difengaged citric acid in the procefs of cryftallization has been already mentioned. This is affifted by adding a little alcohol towards the end of the firft evaporation, and fubfidence for fome hours, interrupting the heat.

Richter gives another procefs for preparing the citric acid, which is fimilar to that of Scheele for procuring the malic acid. It is the following: faturate lemon juice with potafh, and then add a folution of acetited lead, as long as any precipitate, which is very copious, continues to fall down. This is chiefly citrat of lead. Wafh it, and digeft with dilute fulphuric acid, as in the former procefs, which unites with the lead, and fets at liberty the citric acid; then evaporate the liquor to a thick confiftence, add a few drops of nitric acid and cryftallize.

The theory of this operation is the fame as in the former procefs, fubftituting oxyd of lead for lime, but with this difference, that the lemon juice muft be previoufly faturated with potafh, that the acetited lead may be decompofed by the citrat of potafh by *double* affinity; and to prevent any excefs of acid, by which the citrat of lead is readily diffolved, though, without fuch excefs, it is hardly in any degree foluble. However, when this acid is ufed for the table, it is certainly better to prepare it by chalk in Scheele's method, than by fo dangerous a fubftance as lead is, particularly in its acid combinations.

Lemon juice, when fold out of the fruit, is fometimes adulterated with the fulphuric acid. This may be detected in the following way: put a little of it in a glafs, and add a folution of acetited lead as long as any precipitate falls down. This confifts of citrat of lead, mixed with fulphat of lead, if any fulphuric acid was contained in the juice; and of thefe the former is immediately foluble in moderately dilute nitric acid, but the latter not fo. Add, therefore, a quantity of this acid, and if, on ftirring the mixture, the precipitate entirely difappears, and the liquor becomes clear, the lemon juice will be proved to contain no fulphuric acid; but if any of it remains, it will be a pretty fure indication of this acid.

Pure *citric acid* cryftallizes (according to Lowitz) in alum-fhaped cryftals, confifting of two four-fided pyramids joined bafe to bafe, or fometimes in rhomboidal prifms. Its tafte is intenfely four, and, when diluted, very grateful to the palate; but it is fimply an acid tafte, and retains nothing of the aromatic fragrance of the frefh fruit. It is very foluble, one ounce of diftilled water diffolving at a moderate heat, $1\frac{1}{4}$ oz. of the cryftallized acid, and confiderable cold is produced during the folution. Boiling water diffolves twice its weight of the acid. Thefe cryftals are not deliquefcent when pure. Diftilled, *per fe*, the products are an acid empyreumatic phlegm, carburetted hydrogen gas, and carbonic acid. It feems to be compofed of carbon and hydrogen with oxygen in unknown proportions.

If this acid is boiled with a little nitric acid, much nitrous gas is evolved, and the liquor yields by evaporation cryftals of oxalic acid. A greater proportion of nitric acid converts the whole into acetous acid, without giving any indications of paffing through the intermediate ftate of oxalic acid. Thus, Weftrumb obtained 30 grains of oxalic acid, by treating 60 grains of citric acid with 200 grains of nitric acid; with 300 grains of the latter, only 15 grains of oxalic acid, and with 600 grains, not an atom.

Vauquelin afferts that this acid may be obtained by paffing oxymuriatic acid gas through gum-arabic in water for a confiderable time.

The domeftic ufes of citric acid and lemon juice are well known, but of late the concentrated juice and the cryftallized acid have been employed very largely in calico-printing, as difchargers of colour, in order to produce with more clearnefs and effect the white figured parts of coloured patterns dyed with iron colours. It is not abfolutely neceffary to cryftallize the acid for this purpofe, but only to concentrate it. The mineral acids anfwer equally well as difchargers, but when fufficiently concentrated to do this effectually, they injure the texture of the cotton.

The citric acid being extremely expenfive, there may fometimes be reafon to apprehend an adulteration of it even in the cryftallized ftate. The tartaric and oxalic acids refemble it the moft in fenfible properties, and fuch an adulteration could hardly be detected without chemical means. The oxalic is fo expenfive, that it would not, we apprehend, be worth while to employ it for this purpofe; but the tartareous is much cheaper. Any confiderable admixture of this latter acid might be difcovered by the following fimple method: make a faturated folution of fulphat of pot-afh in cold water, and add to it fome of a faturated folution of the acid to be tried; if the tartareous acid is contained, the mixture will depofit in a fhort time a number of minute grains of tartar; but if it confifts only of citric acid, it will remain clear.

Citrats. Thefe are falts formed by the union of the citric acid with alkaline, earthy, and metallic bafes. Only a few of them deferve particular notice. They are all decompofed by heat, which burns off the acid.

Citrat of Pot-afh. This has long been known in medicine under the name of *Riverius's falt.* When ufed medicinally, it is prepared merely by faturating falt of tartar with lemon juice. About 12 to 16 parts of the latter will faturate one part of the common carbonat of pot-afh, or *kali præparatum.* This is fometimes taken in the act of effervefcence; but when this is the intention, the cryftallized carbonat

of

of pot-ash is by far preferable, on account of the large quantity of carbonic acid which it contains. To prepare it more accurately, according to Vauquelin, 36 parts of the cryftallized citric acid diffolved in water require for faturation 61 parts of cryftallized carbonat of pot-afh. This falt cryftallizes, though with difficulty, and is very deliquefcent; 100 parts contain about 55.5 of acid and 44.5 of alkali. It is decompofed by barytes and lime.

Citrat of Soda. This is a very foluble and cryftallizable falt. According to Vauquelin, 36 parts of citric acid require 42 of dry carbonat of foda, fo that 100 parts of this falt confift of 60.7 of citric acid and 39.3 of foda.

Citrat of Ammonia. This falt is employed in medicine as well as the citrat of pot-afh, and then is made extemporaneoufly by faturating lemon juice with carbonat of ammonia. When the folid acid is ufed, 36 parts of it will faturate 44 of carbonat of ammonia. Hence 100 parts of the falt, when dry, will contain 62 of acid and 38 of ammonia. It is very foluble, and difficult of cryftallization.

Citrat of Barytes. This falt confifts of equal weights of citric acid and barytes. When barytic water is poured into a folution of citric acid, a precipitate is formed which is immediately re-diffolved. But when it approaches the point of faturation, the barytic citrat is depofited in quantity, at firft pulverulent, afterwards in fine cluftered cryftalline needles.

Citrat of Magnefia. Thirty-fix parts of the acid require for faturation 40 parts of carbonate magnefia and 100 parts of the falt contain $33\frac{1}{2}$ of magnefia and 66 of real acid. This cannot be cryftallized, but when nearly evaporated to drynefs, the falt rifes in mufhroom-like knobs, white and opake.

Citrat of Lime. This falt, from being the intermede whence the acid is obtained from lemon juice, is by far the beft known. In its neutral ftate, it is but fparingly foluble in water, and the folution has but little tafte. But any excefs of acid renders it extremely foluble. An hundred parts of citric acid mixed with water, and boiled, diffolve 50 parts of citrat of lime. According to Vauquelin, 24 parts of the acid are faturated by 18 of calcareous fpar. Hence 100 parts of the citrat of lime contain 37.34 of lime and 62.66 of acid. Prouft found that 100 parts of the citrat wafhed and dried left by calcination 31.5 of lime, and hence the remaining 68.5 muft be acid and water. Dizé found that the acid required an equal weight of chalk for faturation; hence, fuppofing the chalk to contain 53 per cent. of lime, 100 parts of the dry citrat, quite pure, will confift of 65.4 of acid and 34.6 of earth. This falt kept under water in a warm place foon grows mouldy, the acid is decompofed, and the water is covered with a cruft of carbonat of lime. Citrat of lime is decompofed by the oxalic acid.

Metallic Citrats. Thefe have been but little examined. This acid diffolves zinc and iron readily, and moft of the other metallic oxyds with more or lefs eafe. The acid decompofes acetite of lead, and the citrat of lead is infoluble in water. Citrat of mercury is formed by adding this acid to the nitrat or acetite of this metal. The falt is a flaky precipitate of a brick duft red.

The affinities of this acid appear to be in the following order: barytes, lime, pot-afh, foda, ftrontian, magnefia, ammoniac, and alumine. The comparative affinities of the metallic oxyds have not yet been determined.

CITRIL, in *Ornithology.* See the next article.

CITRINELLA, in *Ornithology*, the citril finch, *citrinella* of Gefner, *Verzellina* of Olina, and *Venturon de Provence* of Buffon. This bird bears fome refemblance to the linnet, it is of a greenifh colour, with the back fpotted with brown, and the legs flefh-colour; its note is delightful, and it is for this reafon kept in cages in many parts of Italy. See FRINGILLA *citrinella.* The common yellow-hammer is alfo named fpecifically *citrinella*, but is of the *emberiza* genus. See EMBERIZA *citrinella.*

CITRINUS, in *Natural Hiftory*, the name of a peculiar fpecies of fprig cryftal, which is of a beautiful yellow. Many of the common cryftals, when in the neighbourhood of lead mines, are liable to be accidentally tinged yellow, by an admixture of the particles of that metal; and all thefe, whether finer or coarfer, have been too frequently confounded together, under the name *citrine.* It is never found colourlefs, like the other cryftals, but has a great variety of tinges, from that of deeper ochres to a pale lemon-colour. It is very plentiful in the Weft Indies, and is found in fome parts of Bohemia. Our jewellers have learnt from the French and Italians, who are very fond of it, to call it *citrine*, and often cut ftones for rings out of it, particularly out of the pyramid, which is always finer than the column, and thefe, after they have paffed through two or three hands, are generally miftaken for topazes.

CITRON, in *Botany.* See CITRUS.

CITRON-*water*, a well known ftrong water, or cordial, which may be thus made: take of fine thin lemon-peel eighteen ounces, of orange-peel nine ounces, perfect nutmegs one quarter of a pound, alcohol perfect, that is, the fineft and beft rectified fpirit of wine, two gallons and a half; digeft in balneo mariæ for one night; draw off with a flow fire; then add as much water as will juft make the mixture milky (which will be about feven quarts or two gallons) and add alfo about two pounds of fine fugar-candy.

This compofition may be improved by frefh elder flowers hung in a cloth in the head of the ftill, fprinkled with ambergrife in powder, or its effence. Otherwife; citron-water may be made, by taking dry yellow rinds of citrons three pounds; two pounds of orange-peel; three quarters of a pound of bruifed nutmegs; ten and a half gallons of clear proof fpirit, and one gallon of water, digefting them with a gentle heat, drawing off ten gallons in balneo mariæ, and dulcifying with fine fugar.

CITRON-*wood*, the wood of an American tree, called by the natives candle-wood, becaufe, being cut into fplinters, it burns like a candle. The tree is frequent in the Leeward Iflands, and grows to a confiderable fize; the leaves are like thofe of the bay tree, but of a finer green; the flower is fweet, and much like thofe of the orange; the fruit fucceeding thefe is black, and of the fize of a peppercorn. The trunk is fo like the yellow faunders in colour, that there was an opinion that it was the fame tree, and much of it was imported into Europe, and fold as fuch; but they were foon found to be different, the true faunders being of a fweet fcent, and but moderately heavy and refinous, but the citron-wood is confiderably heavy, very oily, and of a ftrong fmell. It is of no known ufe in medicine, but is ufed in France and Germany by the turners, being a firm fine-grained wood, and taking a fine polifh, and with age becoming of a very beautiful brown.

CITRONVOGEL, in *Ornithology*, one of the fynonymous names of the crefted oriole, *oriolus criftatus.* Gmelin.

CITROSINA, in *Botany*, Bofc. Nouv. Dict. Flor. Peruv. Pl. 29. Clafs and order, *diæcia icofandria.*

Gen. Ch. *Cal.* Perianth campanulate or pitcher fhaped; border four or eight-toothed. In the *male*, filaments from feven to fixty, petal-fhaped, ovate, flattened. In the *female*, germs fuperior, from three to ten; ftyles tubular; ftigmas fimple. *Peric.* Berry egg-fhaped, flefhy, umbilicate, covered by the calyx and crowned with its border, one-celled, opening unequally, and with elafticity, for the difperfion of the feeds.

 Seeds

Seeds from three to ten, egg-ſhaped, oſſeous, half enveloped in a fleſhy aril. Seven ſpecies, all ſhrubs, with the ſmell of the citron, are mentioned in the Flora Peruvienſis. Boſc.

CITRULLUS, in *Botany*, J. Bauh. See CUCURBITA *citrullus*.

CITRUM. The *citreæ menſæ* have been ſuppoſed by ſome to be made of the citron tree, and by others of the cedar; but it appears plainly that they were made of neither, but of a wood peculiar for its fineneſs, and very different from both. The ancient Greeks have deſcribed the ceder under the name κεδρ☉-, and the citron tree under the name *malus medica;* and beſide theſe, they have deſcribed another tree under the name of *thya*.

CITRUS, in *Botany*, (derivation unknown), Linn. Gen. 901. Schreb. 1218. Willd. 1391. Gært. 705. Juſſ. 261. Vent. vol. iii. 155. Claſs and order, *polyadelphia icoſandria*. Nat. Ord. *Bicornes*, Linn. *Aurantia*, Juſſ. *Heſperideæ*, Vent.

Gen. Ch. *Cal.* Perianth one-leafed, five-cleft, ſmall, withering. *Cor.* Petals five, oblong, ſpreading. *Stam.* Filaments about twenty, forming a cylinder, united at the baſe in ſeveral ſets or brotherhoods, awl-ſhaped, compreſſed, erect. *Piſt.* Germ ſuperior, roundiſh; ſtyle cylindrical, the length of the ſtamens. *Peric.* Berry with a fleſhy rind, many-celled; cells ſeparated from each other by a thin tranſparent membrane, filled with a mucilaginous pulp, in numerous ſeparate bladder-like veſicles. *Seeds*, cartilaginous, from one to four in each cell, attached to the interior angle.

Eſſ. Ch. Calyx five-cleft. Petals five. Stamens about twenty, polyadelphous. Berry many-celled.

Sp. 1. C. *medica*, Linn. Sp. Pl. 1. Mart. 1. Poir. 1. Willd. 1. (Malus medica, Bauh. Pin. 435.) "Petioles linear; leaves egg-ſhaped, acuminate." Willd. Citron. Miller mentions two kinds of the proper citron, one ſweet, with a thick rough-rinded fruit, which he calls C. medica; the other ſour, with a rough knobbed-rinded fruit, which he calls tuberoſa. *β*. C. Limon. Common lemon. Black tab. 362. Brown. Jam. 309. n. 6. Sloan. Jam. 2. 178. Lam. Illuſt. tab. 639. fig. 2. Woodv. Medical Botany, vol. iii. Pl. 184.) "Leaves ovate-lanceolate, acuminate, ſomewhat ſerrated." Miller. *γ*. C. acris. Lime. "Leaves egg-ſhaped, entire; branches ſomewhat entire." Miller. Miller has another variety which has ovate-lanceolate, ſomewhat ſerrated leaves, and the fruit in cluſters. All theſe varieties have linear petioles, and are therefore referred to one ſpecies by all botaniſts: but as, in popular language, they are known by different names, it were to be wiſhed that, upon minute inveſtigation, they might be found to poſſeſs diſtinct ſpecific characters. The fruit of the proper citron is oblong, with a very thick rind; that of the lemon oblong, with a nipple-like protuberance at the end; and that of the lime egg-ſhaped, without the protuberance, with a very thin rind, and about the ſize of the egg of a bantam hen, not half ſo large as a lemon; but theſe characters are not quite conſtant. According to Miller, the bark of the citron is ſmoother, and the wood leſs knotty, than that of the lemon. In their wild ſtate, ſome of them are ſaid to attain to the height of ſixty feet; in our greenhouſes they are neceſſarily reſtrained to a more moderate ſize. The citron is a native of all the warmer regions of Aſia. It was firſt introduced into Europe from Media, whence it obtained the name of malus medica. It ſeems to have been brought into Italy after the age of Virgil and Pliny, but before that of Palladius, who cultivated it with ſucceſs. Its fruit is ſeldom eaten raw, but preſerved as a ſweet-meat, in which form it is now ſent to North America and Europe from the Weſt Indies, where it has long been propagated. The lemon is alſo a native of the Eaſt, but, as well as the orange, has long been naturalized in the ſouth of Europe. Its juice is much uſed in England as an ingredient in the liquor called punch; mixed with ſugar and water, it affords a cooling beverage in hot weather, and is alſo introduced at the table as a condiment to different kinds of meat. Its virtues as an antiſcorbutic are well known; and on that account it is now generally carried on board ſhips deſtined for long voyages; but even when well depurated of its mucilage, it is found to ſpoil by long keeping. To preſerve it in purity, it is neceſſary that it be brought to a highly concentrated ſtate. See CITRIC *Acid*. Its rind is employed various ways in cookery, as a grateful aromatic bitter, not ſo hot as that of the orange. The lime is a native of the Eaſt, but has long been cultivated in the Weſt Indies and the warmeſt parts of North America. In what are called the ſea iſlands of South Carolina and Georgia, it is produced in great perfection. Its juice is eſteemed a much more grateful acid than that of the lemon, which is there in little repute, and comparatively ſeldom ſeen. A plate of limes is a conſtant diſh at entertainments in the Weſt Indies and the ſouthern ſtates of North America, and the juice is ſqueezed into ſoups, turtle, &c. by the gueſts. The lime in Jamaica, according to Brown, is a buſhy ſhrub ſeldom leſs than twelve or fourteen feet high, and by its ſpreading prickly branches affords an impenetrable fence to the ſugar cane plantations. Numerous varieties of all the kinds have been produced by cultivation, but the enumeration and deſcription of theſe are more properly within the province of the gardener than of the botaniſt. From one of them the perfume called BERGAMOT is obtained, which is ſaid to have derived its name from Bergamo in Italy, where the variety was firſt cultivated in Europe, and where it is ſtill preſerved. 2. C. *angulata*, Willd. 2. (Limonellus anguloſus; Rumph. Amb. 2. tab. 32.) "Petioles naked; leaves egg-ſhaped, acute; fruit angular." Certainly a diſtinct ſpecies. *Fruit* ſmall, glutinous, four or five-angled. *Peduncles* ſolitary, axillary. *Spines* two, ſtipular. Willd. 3. C. *madurenſis*, Lam. 8. Lour. Flor. Cochin. p. 570. n. 4. (Limonellus madurenſis, Rumph. Amb. vol. ii. tab. 31.) "Without thorns; branches diffuſe, angular; petioles linear; fruit globular; flower very ſmall." A ſhrub not more than three feet high. *Branches* crooked, often without ſpines. *Leaves* large, egg-ſhaped, rather acute, almoſt entire, quite ſmooth. *Flowers* near the extremities of the branches, almoſt ſolitary, ſweet-ſcented. *Fruit* globular, ſmall, even-ſurfaced, yellowiſh green, half an inch or more in diameter, eight or nine-celled, filled with a veſicular bitter pulp. A native of China and Cochinchina, where it is cultivated for its beauty. 4. C. *buxifolia*, Poir. Encyc. 6. "Leaves nearly ſeſſile, ovate-retuſe; flowers in racemes, very ſmall." *Branches* ſpreading, thorny; thorns ſtiff, erect, yellowiſh at the point. *Leaves* ſcattered, alternate, reſembling thoſe of box, but twice as large, obtuſe, often emarginate, narrowed at the baſe, coriaceous, entire, nerved; nerves near together, ſtrongly marked, parallel; petioles very ſhort, ſimple. *Flowers* white, in ſmall racemes near the extremity of the branches. In its ſhort ſtiff branches, thorns, and the form and firmneſs of its leaves, it has much of the habit of rhamnus pyracantha. A native of China, deſcribed by Poiret from dried ſpecimens without fruit, ſent to La Marck by Sonnerat. 5. C. *margarita*, Poir. 9. Lour. Flor. Cochin. p. 570. n. 5. "Branches aſcending, thorny; petioles linear; berries five-celled, oblong." A ſhrub, four feet high. *Leaves* lanceolate, quite entire. *Flowers* white, ſweet-

ſweet-ſcented, ſcattered on the branches, few together on a common peduncle. *Fruit* not more than eight lines long, ſmooth, yellowiſh red, with a very thin rind, and a ſweet veſicular pulp. A native of China, in the neighbourhood of Canton, remarkable for the ſmallneſs of its fruit. 6. C. *nobilis*, Poir. 7. Lour. Flor. Cochin. p. 569. n. 3. Rumph. Amb. tab. 34. "Without thorns; branches aſcending; petioles linear, ſtiff and ſtraight; fruit tubercled, ſomewhat compreſſed." A tree of a moderate ſize. *Leaves* ſcattered, lanceolate, quite entire, dark green, ſhining, very odorous. *Flowers* white, ſweet-ſcented, in terminal racemes. *Fruit* roundiſh, a little compreſſed, about nine-celled, red within and without, about twice the ſize of a China orange; rind thick, ſucculent, ſweet. It has the fruit of an orange, but the petioles of a citron or lemon, and ſeems a connecting ſpecies between C. medica, and C. aurantium. Loureiro's deſcription agrees exactly with Rumphius's figure. A native of Cochinchina. 7. C. *aurantium*, Linn. Sp. Pl. 2. Mart. 2. Poir. 2. Willd. 4. Lam. Ill. tab. 639. fig. 1. orange. "Petioles winged; leaves acuminate; ſtem arboreous," Willd. α. Seville or ſour orange (Thunb. Flor. Jap. p. 293. Lour. Flor. Cochin. p. 569. Rumph. Amb. tab. 33. (malus aurantia major, Bauh. Pin. 436. Blackw. tab. 349. Ferr. Heſp. tab. 377. β. China or ſweet orange, (malus aurantia cortice eduli, Bauh. Pin. 436. Ferr. Heſper. tab. 433.) "Leaves lanceolate, acute, ſmooth," Mil. A middle-ſized tree, with a greeniſh brown bark. *Branches* generally ſpinous. *Leaves* thick, ſhining, ſmooth, ovate-lanceolate, alternate, not at all, or very little toothed; ſprinkled with ſmall, reſinous, tranſparent tubercles, reſembling thoſe in ſome ſpecies of hypericum. *Flowers* white, very odorous, in ſhort racemes towards the end of the branches; filaments united at firſt by an entire membrane, which afterwards becomes torn, and forms ſeveral ſets of ſtamens. *Fruit* round, compreſſed into the ſhape of an oblate ſpheroid, yellow; rind fleſhy, rather thick, containing a number of veſicles, filled with a volatile or eſſential oil, which ſpirts out when the rind is preſſed by the finger nail. A native of the Eaſt Indies, but naturalized in the ſouth of Europe, as well as in the Weſt Indies, and the ſouthern part of North America. The China orange flouriſhes only on the ſea iſlands of South Carolina and Georgia, intermingled with the lemon and lime. The Seville orange is hardier, and is found in the upper part of the country. Evelyn informs us, that the firſt China orange, which appeared in Europe, was ſent for a preſent to the old Conde Mellor, then prime miniſter to the king of Portugal; but of the whole caſe ſent to Liſbon, there was only one tree which lived, and became the parent of all the flouriſhing trees ſince cultivated by the gardeners. Biſhop Gibſon, in his additions to Cambden's "Britannia," ſays, probably from Aubrey, that the orange trees at Beddington in Surrey, introduced from Italy by Sir Francis Carew, were the firſt that were brought to England; that they were planted in the open ground, under a moveable covert during the winter months; and that they had been growing there more than a hundred years, *i. e.* before 1595. Theſe trees all periſhed in the great froſt of 1739-40. It has alſo been ſuppoſed to be a native of the Heſperides, or Canary Iſlands, and its fruit to be the golden apples which the daughters of Heſperus cauſed to be ſo ſtrictly guarded by a dragon. Under this idea, Ventenat has changed the name of the natural order to which it belongs, from Aurantia to Heſperideæ. There are more varieties of this ſpecies than of C. medica. Poiret enumerates and deſcribes eighteen of the citron, eleven of the lemon, and forty-four of the orange, all cultivated in the Paris gardens; but obſerves, that with reſpect to ſome of them, it is not eaſy to determine whether they ought to be referred to C. medica, or C. aurantium. The ſmell of the orange flower is almoſt univerſally eſteemed. Du Tour, in "Nouveau Dictionaire d'Hiſtoire Naturelle," is quite eloquent in its praiſe. "The ſcent of the orange flower," expatiates that lively writer à la mode Françoiſe, "is regarded as a ſtandard of perfection in its kind. It has not, like that of many flowers, a deceitful ſweetneſs, which pleaſes only to injure. It is not faint, like the ſcent of jaſmine or reſeda; it does not affect the head like narciſſus or tuberoſe; it does not weaken the nerves, but rather ſtrengthens them; it is a ſalutary odour, which refreſhes the ſenſes and enlivens the brain. In fine, it has no rival, and is as ſalutary as it is delicious." Theſe flowers are much uſed in perfumes and ſcented waters, yielding their flavour by infuſion to rectified ſpirit, and in diſtillation both to ſpirit and water. An oil diſtilled from them is brought from Italy under the name of oleum, or eſſentia neroli. The juice of the fruit is a grateful liquor, which, by allaying heat, quenching thirſt, and promoting various excretions, proves of conſiderable uſe in febrile and inflammatory diſeaſes. It is only that of the Seville orange which has a place in the materia medica of our Britiſh pharmacopœias; but that of the China orange, having a larger quantity of ſaccharine matter, is more agreeable to the taſte, and may be uſed more freely. Theſe acids, by uniting with the bile, are ſaid to take off its bitterneſs; but if they are in greater quantity than can be properly corrected by the bile preſent, they ſeem, by ſome union with that fluid, to acquire a purgative quality, that gives a diarrhœa, and the colic pains, that are ready to accompany the operation of every purgative. The outer yellow rind of the fruit is a grateful aromatic bitter; by the union of theſe qualities, it warms the ſtomach, promotes appetite, and gives tone and ſtrength to the viſcera; but Dr. Cullen obſerves, that its virtues are not ſufficiently experienced, becauſe we employ it chiefly in its dried ſtate, and in too ſmall a proportion, as we take with it part of the white inert ſubſtance that compoſes the inner rind. Its flavour is likewiſe ſuppoſed to be leſs periſhable than that of the lemon; hence the London college employ orange-peel in the ſpirituous bitter tincture, which is deſigned for keeping; whilſt in the bitter watery effuſion, lemon-peel is preferred. A ſyrup and diſtilled water are for the ſame reaſon prepared from the rind of oranges in preference to that of lemons. See Woodville's "Medical Botany." 8. C. *fuſca*, Poir. 10. Lour. Flor. Cochin. p. 571, n. 6. Rumph. Amb. 2. tab. 33. "Much branched, thorny; leaves lanceolate, egg-ſhaped; petioles with heart-ſhaped wings; berries globular, rough." A large tree. *Branches* numerous, crooked, almoſt erect, furniſhed with long ſtout ſpines. *Leaves* quite entire, dark-green, ſtrong-ſcented. *Flowers* white, not very odorous, in nearly terminal racemes. *Fruit* greeniſh brown, eight or nine celled, of a diſagreeable, bitter flavour. A native of Cochin China, where it is one of the moſt common kinds. Poiret regards it as a mere variety of C. aurantium, differing in its nearly ovate-leaves, and the colour of its fruit. It ſeems moſt allied to the Seville orange. 9. C. *humilis*, Poir. 4. (C. aurantium, δ. Mart.) Dwarf or nutmeg orange. "Leaves egg-ſhaped; flowers ſeſſile." A low ſhrub. *Leaves* ſmall, growing in bundles. *Flowers* near together, ſweet-ſcented. Poiret agrees with Miller in regarding this as a diſtinct ſpecies. Profeſſor Martyn makes it a variety of C. aurantium. 10. C. *japonica*, Poir. 5. Mart. 4. Willd. 3. Thunb. jap. 292. Icon. Pl. 15. (Kin Kan. Kæmp. amen. 801.) "Petioles winged; leaves acute, flowers axillary, moſt frequently ſolitary; ſtem ſhrubby." *Stem* ſcarcely a foot high, compreffed-angular, erect. *Branches* and *Branchlets* alternate, compreffed-angular, fpinous, fmooth, erect, green; fpines folitary, axillary, erect, fpreading. *Leaves* fcattered, egg-fhaped, rather acute, quite entire, a little concave, fmooth, deep green above, paler underneath. *Flowers* fnowy-white, rarely two together, peduncled, nodding; peduncles a line long, fmooth, drooping; calyx fmooth, very fmall, five-toothed; petals oblong, a little concave, fpreading; filaments nineteen, awl-fhaped, compreffed, erect, in five fets, forming a cylinder fhorter than the corolla, nearly equal, white; anthers oblong, minute, yellow; germ roundifh, fmooth, ftyle cylindrical, a little fhorter than the ftamens, greenifh white; ftigma globular, yellow, ftriated. *Fruit* with a thick rind, about the fize of a cherry, nine-celled, very fweet and grateful to the tafte. Thunb. Poiret does not venture to pronounce it fpecifically diftinct from the preceding. 11. C. *decumana*, Murray, Syft. Veg. 580. Mart. 3. Poir. 3. Willd. 5. (C. aurantium γ; Linn. Sp. Pl. Limo decumanus; Rumph. Amb. 2. tab. 24. fig. 2. Malus aurantia fructu caput humanum excedente; Sloane Jam. 212. Hift. 1. tab. 12. fig. 2, 3. Thunb. Flor. Jap. 293. Lour. Cochin. 571.) Shaddock. "Petioles winged; leaves obtufe, emarginate." Mur. "Leaves ovate-lanceolate, thick, fhining; fruit very large," Mill. A middle-fized tree, with fpreading, fpinous branches. *Leaves* egg-fhaped, a little acute, feldom obtufe, very feldom emarginate, toothed, petioles with remarkably large heart-fhaped wings. *Flowers* white, very odorous, in long flightly tomentous racemes; petals reflexed; ftamens about twenty, nearly the length of the petals, collected into a many-cleft tube. *Fruit* eight inches in diameter, yellowifh green, even-furfaced, twelve-celled or more, containing fome a red, others a white pulp; the juice in fome fweet, in others acid; rind very thick, of a difagreeable bitter flavour, not efculent. *Seeds* egg-fhaped, fomewhat acute, two or three in each cell. A native of China, Cochin-China, Japan, and the Friendly Iflands. It derives its vulgar name from a captain Shaddock, who firft brought it from the Eaft to the Weft Indies. In England it was cultivated by Miller in 1739. Murray's fpecific character appears to have been very carelefsly formed; and it is rather extraordinary that it fhould have been copied without alteration or addition by Martyn, Poiret, and Willdenow. 12. C. *trifoliata*, Linn. Sp. Pl. 3. Mart. 5. Poir. 11. Willd. 6. (Tfi. f. Karatas bauna; Kæmpf. Amen. tab. 802. Thunb. Fl. Jap. 294.) "Leaves ternate." A fhrub. *Stem* near fix feet high; branches alternate, compreffed-angular, crooked, green, fhining, fpinous; fpines near an inch long, alternate, dilated, and compreffed at the bafe, fpreading, ftiff and fharp, yellow at the end. *Leaves* diftant from each other; leaflets oval, crenulate; petiole with a crenulate wing. *Flowers* white, axillary, feffile, folitary; petals concave, roundifh, clawed; filaments not united at the bafe, much longer than the petals. *Fruit* globular, the fize of a fmall orange, feven-celled; pulp glutinous, with an unpleafant fmell, and bad flavour. *Seeds* oval. A native of Japan, where it is employed for fences, which its crooked thickfet branches and ftiff fharp thorns render impenetrable.

Obf. Loureiro imagined that he found Kempfer's Tfi. v. Karatas, in Cochin China, and as his plant did not accord with the generic character of citrus, he formed for it a new genus, which he has called *triphafia aurantiola*; but a bare infpection of Kempfer's figure is fufficient to fhew that his and Loureiro's plant cannot be the fame. The Cochin-China plant is probably *limonia trifoliata* of Linnæus.

Citrus, in *Gardening*, comprehends plants of the citron, lemon, and orange tree kinds, of which the forts ufually cultivated are, the citron tree, (C. *medica*), the orange tree (C. *aurantium*), and the fhaddock orange (C. *decumana*).

The firft, in its wild ftate, is a tree that grows to the height of about eight feet, erect and prickly, with long reclining branches. The leaves are ovate-oblong, alternate, fubferrate, fmooth, pale green; the flowers white, odoriferous, on many-flowered, terminating peduncles; the fruit a berry, half a foot in length, ovate, with a protuberance at the tip, nine-celled or thereabouts; the pulp white, commonly acid; the rind yellow, thick, hardifh, odoriferous, irregular. The fruit is efculent both in the raw and preferved ftate. It is a native of the warmer parts of Afia.

Of this fort, Martyn obferves, that there are feveral varieties which are procured from Genoa, the great nurfery of this as well as lemons and oranges; the cultivators of them there being, he fays, as fond of introducing a new variety into their collections as nurferymen are here of obtaining a new pear, apple, or peach. There are the citron tree with fweet fruit; with four fruit; and the common lemon, and the lime. But the firft of the two latter varieties, or the lemon tree, differs, according to the fame writer, from the orange, both in the naked foot-ftalks of the leaves, and in the fhape and colour of the fruit; while there is fcarce any diftinction between it and the citron.

It is obferved that the moft remarkable fub-varieties cultivated in this climate are, the fweet lemon, plain and variegated; the pear-fhaped; the imperial; the lemon called Adam's apple; the furrowed fruited; the childing; and the lemon with double flowers.

The fecond, or four lemon or lime, grows in its native climate to the height of about eight feet, with a crooked trunk and many diffufed branches, which have prickles on them. It is a native of Afia, and common in the Weft Indies.

There is another fub-variety, the fweet lime, which, the fame writer fays, is generally a more upright tree, and bears a fruit, which in fize and form feems to hold a mean between the lime and the lemon. But thefe two laft fub-varieties are but little cultivated in this country.

The fecond fpecies is a middle-fized evergreen tree, having a greenifh brown bark, and dividing upwards into a branchy regular head, the leaves broad lanceolated, and the fruit fubglobular, flat, of a golden colour. It is a native of India. Of this fort there are numerous varieties, but thofe moft known in garden culture are, the Seville; the China; the willow-leaved or Turkey; the yellow and white ftriped-leaved; the curled-leaved; the horned; the double-flowering; the hermaphrodite; and the dwarf or nutmeg orange. The firft of which affords a large, rough-rinded, four fruit, of excellent quality for culinary ufes. It is a handfome grower, and the hardeft of the orange tribe, as it fhoots freely in this climate, producing large and beautiful leaves; and flowers ftronger and more abundantly, and generally bears a greater quantity of fruit than any other fort, and arrives to greater perfection.

The fecond has moderate-fized leaves, and a fmooth, thin-rinded, fweet fruit; of which there are feveral fub-varieties in warm countries, where they grow in the open ground. And the willow-leaved orange tree has narrow fpear-fhaped leaves, and a ftriped willow-leaved orange.

In refpect to the horned orange, it is a common-fized tree, producing oblongifh fruit, which divide at the end, the rind running out into divifions like horns. The hermaphrodite orange is a common-fized tree, producing fruit partly like an orange, and partly citron-fhaped. And the dwarf or nutmeg orange has a low ftem, and fmall bufhy head, growing

growing two or three feet high, with ſmall oval leaves in cluſters, and numerous flowers in bunches, covering the branches, ſucceeded by very ſmall fruit. When in flower it is proper to be placed for ornament in rooms or other places, which it perfumes with its flowers; but it requires care, and is ſeldom in a perfect ſtate of growth in this climate.

It is ſaid that the ſtriped and double-flowered varieties are the moſt curious and intereſting.

The third ſpecies is a tree above the middle ſize, in its native place, having ſpreading prickly branches, the leaves ovate, and the flowers white, very ſweet-ſcented, in copious, upright, terminating bunches; the fruit ſpheroidal, of a greeniſh yellow colour. It is a native of India, but introduced into the Weſt Indies by captain Shaddock.

And of this ſort, according to Martyn, there are many varieties, " one of which, ſuperior to the reſt in the flavour and ſmell of the fruit; has a ſmaller trunk, and ſub-globular fruit, five inches in diameter, yellow on the outſide, white and very ſweet within."

Method of Culture. In regard to the method principally practiſed in this climate for raiſing all theſe ſorts of trees, it is that of budding them upon ſtocks raiſed from the ſeeds; but they are likewiſe ſometimes increaſed by the operation of inarching. And new varieties are conſtantly raiſed from the ſeed of the different ſpecies.

Method of raiſing new Varieties and Stocks. With this view ſome ſeed ſhould be provided from the moſt perfectly ripened fruits of the different ſorts that are wanted, early in the ſpring, at which time it ſhould be ſown in pots filled with good light earth, being covered to the depth of about half an inch, plunging them in a tan hot-bed, giving them ſlight ſprinklings of water and a free admiſſion of air. When the plants have attained a tolerably ſtrong growth, which is moſtly in about eight or ten weeks, they ſhould be gradually hardened to bear the full air, in which they may be continued till the weather renders it neceſſary to remove them into the green houſe for protection during the winter.

With ſome, however, in order to get them forward more rapidly, it is the practice to prick them out ſingly, when about two inches in height, into other pots, and plunge them into a ſecond tan hot-bed, watering and giving them freſh air occaſionally, and gradually hardening them as in the preceding manner. In this way they are ſaid to become much larger plants the following year.

But in caſes where the firſt mode is practiſed, the plants ſhould, in the following ſpring, about the middle of March or the beginning of the following month, be ſhaken carefully out of the ſeed-pots, ſo as to preſerve the roots as entire as poſſible, and planted ſeparately in ſmall pots, made about half full with a compoſt of mellow loamy earth, and afterwards filled up with the ſame ſort, ſo as to ſupport the plants well; ſhade and water being occaſionally given, till they become perfectly eſtabliſhed. It is the cuſtom with ſome gardeners, in order to have the plants more forward, as well as more ſtraight and upright, to plunge the pots, as ſoon as the plants have been placed in them, in a tan hot-bed, covered by frames and glaſſes, freſh air and water being duly ſupplied.

In theſe modes of management, the plants are capable of furniſhing good ſtocks for budding upon the ſecond or third year. And where two hot-beds are made uſe of, many of them will be in a proper ſtate for the purpoſe the ſecond year, if proper care be taken of them. See BUDDING.

It is obſerved, that for the purpoſe of ſtocks, the citron, lemon, and Seville orange, are the beſt, as being the ſtrongeſt ſhooters, eſpecially the laſt.

Where any of the plants appear particularly handſome and of a healthy growth, they may be let remain, for the purpoſe of affording new varieties; but they are long in this way of raiſing them before they produce fruit; and when that happens, there is great uncertainty of their poſſeſſing any valuable qualities. After the plants have been thus propagated, they only require the ſame ſort of management as other exotics of the green-houſe kind, to be employed in preſerving them in a healthy ſtate.

Method of Budding them on the Stocks. Theſe plants, when they have acquired twelve or fifteen inches growth, and are about the thickneſs of a large gooſe quill, or rather more, are in a proper ſtate for the purpoſe. The buds ſhould be procured from ſound, plump, young ſhoots, of ſuch trees as have a free growth, and are in a ſtate of bearing, and the operation ſhould be performed about Auguſt, upon ſtocks of the ſame kinds and varieties, the buds being inſerted from ſix to ten or more inches from the bottom, in proper parts of the ſtocks, and only one bud in each of them. See BUDDING.

As ſoon as this has been done, the plants ſhould be removed into the green-houſe, a frame, or old tan hot-bed, in order to guard them from the wet, and promote the inoſculation of the veſſels, and the healing of the parts; due ſhade and air being occaſionally given; and when the union is perfectly accompliſhed, the ligatures be removed, to permit the ſwelling of the plants, without injury being done by their pinching them.

There is nothing more neceſſary afterwards, than the application of proper ſupplies of moiſture and air, with ſuitable protection from rain and all ſorts of dampneſs. When the heads of the ſtocks have been removed in the early part of the following ſpring, the buds begin to ſhoot with vigour, eſpecially where the aid of a tan hot-bed can be had recourſe to. The plants ſhould now be enured by degrees to the full air, for the latter part of the ſummer, and in the autumn and winter have the protection of a green-houſe given them.

Method of raiſing by Inarching. When this mode is employed, which is now but ſeldom the caſe, as the budding practice is much more convenient, and the trees more ornamental, the young ſhoots of the trees raiſed in the above modes, which are nearly of the ſame ſize as the ſtocks, ſhould be joined with them in the early ſpring months, ſo as to conſtitute a ſort of arch; and in the latter end of ſummer they are moſtly in a ſtate to be taken off from the parent-tree. See INARCHING.

By this mode, the trees may be raiſed to a bearing ſtate in a very ſhort time, as the young bearing branches may be made uſe of for the purpoſe, by which a new bearing tree is at once produced. And different ſorts may be connected, and produced on the ſame tree. But the trees furniſhed in this way are never ſo beautiful as thoſe produced by that of budding, in the manner deſcribed above.

Method of Culture in the trained Trees. It is the cuſtom, in order to have trees of this ſort at once, to purchaſe ſuch as are brought from Italy, &c. in cheſts in the ſpring. They are of different ſizes, and, when properly managed, produce as good trees in two years, as thoſe raiſed in the above modes can in a great many. It is neceſſary to obſerve, that in chooſing theſe trees, thoſe which ſhoot the moſt vigorouſly are moſtly of the citron or ſhaddock kind, as the orange rarely grows with ſuch luxuriance. The laſt, therefore, as being more valuable, ſhould be attended to. And as ſome are only furniſhed with one bud, while others have two, the latter ſhould be preferred, as they will produce the moſt regular headed plants in moſt caſes.

And theſe trees, after having had their roots cleaned, trimmed,

med, and well soaked in water for some time, as well as the stems and branches cleaned, should be planted separately in tubs or pots of suitable sizes, filled with earth of the same sort as mentioned above, watering them at the time, and plunging them in the tan-bed of the stove to the tops of the plants, &c. They should continue in this situation some time, and be well watered, both at the bottom and over their heads, shade being given when necessary, and a due proportion of air when they begin to shoot in the heads. These should likewise be cut occasionally, in order to induce them to throw out lateral branches, and form full handsome heads, air now being more freely admitted, to render the plants hardy, and capable of being preserved in the green-house during the following winter, being managed as other plants of the exotic green-house kind.

General Method of Management in all the Sorts. As it is necessary that these trees should be moved into different situations, it is mostly proper to have them in pots or large tubs; and where there are suitable glass frames for protecting them in winter, a few may be planted out against walls which have flues that can be heated as there may be occasion. None of the sorts can be preserved in the open air except during a few of the summer months. The management in which cases is that of placing them in some warm public situation, at first washing their heads well with water, to remove dust or other substances, supplying them frequently with a little water when the season is hot, and preserving the moisture in the earth of the pots, by covering it with new cut-short grass. When they are removed to the green-house, on the approach of the autumn or winter, they should be deposited in a regular order, the largest to the back parts, proper supplies of fresh air and water being given when the weather is suitable, and due protection provided against frost. It is occasionally necessary also to water them over head, to remove all sorts of insects and other substances that may be upon their leaves, when all the decayed parts should be wholly removed and dressed away. And as often as the earth in the pots or tubs begins to bind or become stiff, it should be loosened to the depth of a few inches; and in the spring, it is useful to remove a little of the surface, re-placing it by such as is fresh, as by these means the plants thrive better and continue more healthy. It becomes necessary in most cases to shift the plants into larger pots or tubs of fresh earth every second or third spring, about April, removing them with the balls of earth entire, the outside matted mouldy roots being pared off close, and part of the old earth at the top, sides, and bottom taken away; then the tubs or pots being cleaned out, or new larger ones provided, some crooked pieces of tiles should be laid over the holes at bottom, and some earth put in, placing the trees in the pots or tubs, and filling them up with more compost, pressing it down on the sides, giving a moderate watering at the tops, and retaining the plants in the green-house till the weather becomes sufficiently fine for their being set out. And such trees as have thin, straggling, or irregular heads, should now be pruned, so as to have the branches moderately short, and to form better heads.

But it is advised, that when they appear in an unhealthy state, with weak shoots, irregular heads, and small ill-coloured leaves, they should be pruned pretty close, and shifted into entire fresh earth, the roots being soaked and washed well with water. When they have been again planted, they should have a little water given immediately, and be plunged in a bark hot-bed, to remain until July, when they will have made strong shoots, and have formed new, full, and regular heads in a handsome manner.

When such of the trees as are in pots have attained a large size, they should be shifted into tubs hooped with iron hoops, having strong hooked iron handles at the tops, to receive poles to lift the trees by in removing them.

As there is often an abundance of flowers on these trees, when they appear in June and the following months, it may be proper to thin them a little by taking off the smallest; and as the trees continue blowing and setting fruit for some time, when a full crop is set, it is of benefit to the trees and fruit to gather off the superabundant blossoms as they are formed on the trees.

And in planting trees of this kind in the full ground, there must be frame-erections for the support of glass or other coverings, to defend the plants in inclement weather: in these situations, the trees, from their having full scope for their roots, generally shoot strong, and produce large fruit, being trained within as wall or standard trees. But the walls for this purpose should have a southern aspect, and be in a dry situation; and for the greater protection of the trees in severe frosts, there should be a fire-place with a flue carried along a low wall in the front and ends, the trees being planted in the full borders against the back walls, and their branches trained to them five or six inches distance, air and occasional water being given, as for those in the green-house, and the glasses put on in nights in bad weather, the flues being only made use of in sharp frosts, and then with very moderate fires, so as just to prevent their injurious effects.

Having managed them in this way during the autumn, winter, and spring seasons, they should about the beginning of June have the glasses removed, and the borders raised a little where the soil is wet, and be slightly dug over two or three times a year, necessary supplies of manure being given. And for standard trees, a more capacious and lofty glass covering should be erected against the wall somewhat in the manner of hot-houses, only higher, a border being made the whole width and length, planting one or two rows of trees lengthways in it, suffering them to run up as standards, only giving a little pruning, just to preserve regularity in their heads.

With some it is the custom to have for this use lofty moveable glass frames, so that two or three rows of trees can be planted in some conspicuous part of the pleasure-ground, the frames being taken wholly away in summer, so as to appear a little orange grove. And when the trees are well protected by the glasses and other occasional coverings, &c. in winter, they grow in this way to a much greater height than those planted in tubs, or other methods.

It is necessary to observe, that the citron trees should have warmer situations than those of the orange kind during the winter, and be retained in the house later in the summer, at which period they should also have rather more water given them.

And the common lemon trees, as being more hardy than the orange, should of course have more air in the winter season, when the weather is suitable for its being admitted.

CITTA, in *Botany*, Bosc. Nouv. Dict. Loureir. Flor. Cochin. (Lobus littoralis, Rumph.) Class and order, *diadelphia decandria*.

Gen. Ch. *Cal.* bilabiate, humped, coloured, hispid; upper lip entire; lower lip three-cleft; segments awl-shaped, the middle one the longest. *Cor.* papilionaceous; standard almost naked, humped at the base; wings oblong, connivent; keel recurved. *Stam.* Filaments ten, nine united at the base, five alternate ones larger; anthers oblong. *Pist.* Germ superior, oblong, villous; style filiform; stigma almost round. *Peric.* Legume oval, oblong, thick, compressed, hispid, hollowed externally into square cavities. *Seeds* three, large, compressed, arilled.

Sp.

Sp. C.—A climbing ſhrub. *Leaves* ternate, petioled; leaflets egg-ſhaped, acute, quite entire, ſmooth. *Flowers* almoſt black, ſpotted with white, in axillary corymbs. A native of Cochin China.

CITTA, in *Medicine*, κίττα, is ſynonymous with *pica*, a term generally uſed to denominate a depraved appetite, which craves for indigeſtible ſubſtances, ſuch as chalk, earth, &c. See PICA.

CITTA CASTELLANA, in *Geography*, a town of Italy, in the ſtate of the church, and patrimony of St. Peter; once the ſee of a biſhop united with Orta; 23 miles N. of Rome.

CITTA DI CASTELLO, a town of Italy, in the province of Umbria, ſeated on the Tiber, the ſee of a biſhop; containing 10 churches, and a great number of convents; 23 miles S.W. of Urbino, and 97 N. of Rome.

CITTADELLA, a ſea-port town of the iſland of Minorca, with a good harbour, on the N.W. coaſt, ſurrounded with walls and baſtions; it contains two churches, four convents, and 600 houſes. N. lat. 40° 2′. E. long. 4° 3′.—Alſo, a town of Italy, in the Paduan; 19 miles N.N.W. of Padua.—Alſo, a town of the Paduan, near the Brenta, between Vicenza and Trevigno.

CITTA DUCALE, a town of Naples, in the province of Abruzzo Ultra, founded in 1308, by Robert, duke of Calabria, and almoſt ruined by an earthquake in 1703; the the ſee of a biſhop; 18 miles W. of Aquila.

CITTA DELLA PIEVE, a town of Italy, in the province of Perugia; the ſee of a biſhop; 18 miles W. of Perugia, and 68 N. of Rome.

CITTA DEL SOLE, a town of Italy, in the duchy of Tuſcany, built in the year 1565, by Coſmo I. duke of Tuſcany; 16 miles S.S.W. of Ravenna.

CITTA NUOVA, a town of Iſtria; 7 miles S. of Umago.

CITTADINI, PIER-FRANCESCO, called *Il Milaneſe*, in *Biography*, a painter very much eſteemed for his ſmall pictures. He was born at Milan in the year 1626; but at a very early period ſettled in Bologna, where he is ſaid to have been inſtructed by Guido: he ſoon became admired for the univerſality of his genius, and the beauty and freedom of his painting; and it is thought he would have proved one of the greateſt artiſts of his ſchool, had he not ſo entirely devoted himſelf to painting in ſmall. His little pictures, whether repreſenting rural feaſts, dances, ſpectacles, or landſcapes, are equally admired; and his repreſentations of fruit, flowers, and ſtill life, are conſidered ſuperior to thoſe of any of his Bologneſe cotemporaries. Many of his works are in the collections at Bologna, where he died, in the year 1681. Lanzi, Storia Pittorica. Orlandi. Creſpi.

CITTADINI, CARLO, GIO. BATISTA, and ANGIOL MICHELE, three ſons of Pier-Franceſco Cittadini, were all of them painters of ſome note, in the ſtyle of their father. Carlo and Gio. Batiſta, like him, excelled equally in figures and in ſtill life; but Angiol Michele principally confined himſelf to pictures of fruits and flowers. Carlo had two ſons, GAETANO, a good landſcape painter, and GIO. GIROLAMO, who, like his uncle Angiol Michele, ſatisfied himſelf with the more humble province of dead game, flowers, and other ſtill objects. Gio. Batiſta died in 1692. Gio. Girolamo was living towards the latter part of the 18th century. Lanzi. Orlandi. Creſpi.

CITTERN, or GETERN, corrupted from the Spaniſh, *citara*, a guitar, and *citron*, a guitar-maker.

CITTOWIANY, in *Geography*, a town of Samogitia; 10 miles N. of Roſienne.

CITULA, in *Ichthyology*, the name given by Paulus Jovianus, and others to the common dory, or doree, *zeus faber* of modern naturaliſts. Pliny calls it *zeus*; and hence Artedi adopted the ſame as a generic name for this and ſeveral other fiſhes of the ſame natural family.

CITUS, is the name given by Salvian (*aquat.*) to the *cottus gobio* of later naturaliſts; and *river bull-head* of Engliſh writers.

CITY, or CITTY, *Urbs*, a large town incloſed with a wall; or a town incorporated, which is or hath been the ſee of a biſhop.

It is hard to give any juſt definition of a city; becauſe cuſtom has reſerved the appellation of towns, to many places which ſeem to have every thing requiſite to conſtitute cities. Formerly city, according to ſome, was only underſtood of ſuch towns as were biſhops' ſees: which diſtinction ſeems ſtill to hold in England, though no-where elſe. See BISHOP and DIOCESE.

According to Cowel, city, or civitas, is a town corporate, which hath a biſhop and cathedral church, which is called *civitas, oppidum*, and *urbs*; *civitas*, becauſe it is governed by juſtice and order of magiſtracy; *oppidum*, as it contains a great number of inhabitants; and *urbs*, becauſe it is in due form begirt about with walls. But Crompton, in his Juriſdictions, where he reckons up the cities, omits Ely, although it has a biſhop and a cathedral church, and inſerts Weſtminſter, though it hath not now a biſhop: and ſir Edward Coke makes Cambridge a city, and yet there is no mention of its ever having been an epiſcopal ſee. It appears, indeed, by the ſtat. 35 Hen. VIII. c. 10, that Weſtminſter had a biſhop; ſince which time, in ſtat. 17 Eliz. c. 5, it is denominated a city or borough: and notwithſtanding the obſervation of Coke with reſpect to Cambridge, in the ſtat. 11 Hen. VII. c. 4, Cambridge is called merely a town. We learn, however, from Burnet's Reformation (Appendix), that Weſtminſter retained the name of city, not becauſe it had been a biſhop's ſee, but becauſe it was expreſsly created ſuch in the letters-patent by king Henry VIII., erecting it into a biſhopric. There was a ſimilar clauſe in favour of the other five new created cities, *viz.* Cheſter, Peterborough, Oxford, Glouceſter, and Briſtol. Mr. Hargrave, in his Notes to 1 Inſt. 110, proves, that although Weſtminſter is a city, and has ſent citizens to parliament from the time of Edward VI., it never was incorporated: and this is a ſtriking inſtance in contradiction to the learned opinion there referred to; *viz.* that the king could not grant, within time of memory, to any place the right of ſending members to parliament, without firſt creating that place a corporation. Lord Coke ſeems anxious to rank Cambridge among the cities; and Mr. Woodeſon, late Vinerian profeſſor (ſee his Lectures, i. 302.), has produced a deciſive authority that cities and biſhop's ſees had not originally any neceſſary connection with each other. It is that of Ingulphus, who relates, that at the great council aſſembled in 1072, to ſettle the claim of precedence between the two archbiſhops, it was decreed that biſhops' ſees ſhould be transferred from towns to cities. The above authority derives ſtrong confirmation from the fact, that the ſame diſtinction was not paid to biſhops' ſees in Ireland.

The term city had its riſe, among us, ſince the Conqueſt; for in the time of the Saxons there were no cities, but all great towns were called burghs. Thus, London was called London burgh; as the capital of Scotland is now called Edinburgh.

And for a long time after the Conqueſt, city and burgh were uſed promiſcuouſly. Thus, in the charter of Leiceſter, that place is called both *civitas* and *burgus*; which ſhews that lord Coke and other writers are miſtaken, who tell us that every city was, or is, a biſhop's ſee. Hence it ſhould ſeem, that though the term city signifies with us such a town corporate as hath usually a bishop and a cathedral church, yet it is not always so.

However, Chassanæus, "De Consuetud. Burgund." says, France has within its territories 104 cities; and gives his reason, because it has so many archbishops and bishops.

Cities and villages held formerly, in the time of the feudal government, of some great lord, on whom they depended for protection; and to whose arbitrary jurisdiction they were subject: and the inhabitants were deprived of the natural, and most unalienable rights of humanity.

They could not dispose of the effects, acquired by their own industry, either by will, or by any deed executed during their life. They had no right to appoint guardians for their children, whilst they were minors. They were not permitted to marry without purchasing the consent of the lord on whom they depended. If once they commenced a law-suit, they were not allowed to terminate it by an accommodation, because the lord in whose court they pleaded would thus have been deprived of the perquisites due to him in passing sentence. Services of various kinds, equally disgraceful and oppressive, were exacted from them without mercy or moderation. The spirit of industry was checked in some cities by absurd regulations, and in others by unreasonable exactions; nor would the narrow and oppressive maxims of a military aristocracy have permitted it ever to rise to any degree of height or vigour. But as soon as the cities of Italy began to turn their attention to commerce, and to conceive some idea of the advantages which they might derive from it, they became impatient to shake off the yoke of their insolent lords, and to establish among themselves such a free and equal government as would render property secure, and industry flourishing. Concurring circumstances encouraged the inhabitants of some of the Italian cities, towards the beginning of the 11th century, to assume new privileges, to unite more closely together, and to form themselves into bodies politic, governed by laws established by common consent. The rights which many cities acquired by bold or fortunate usurpation, others purchased from the emperors, who deemed themselves gainers when they received large sums for immunities which they were no longer able to withhold; and some cities obtained them gratuitously from the generosity or facility of the princes on whom they depended. The great increase of wealth, which the crusades brought into Italy, occasioned a new kind of fermentation and activity in the minds of the people, and excited such a general passion for liberty and independence, that before the conclusion of the last crusade, all the considerable cities in that country had either purchased or extorted large immunities from the emperors. As soon as their liberties were established, and they began to feel their own importance, they endeavoured to render themselves masters of the territory round their walls; which, under the Romans, belonged to each town, but which under the prevalence of the feudal policy had been seized and shared among the conquerors. The barons, to whom the circumjacent lands were granted, erected their castles almost at the gates of the cities, and exercised their jurisdiction there. Many of the cities in Italy attacked their troublesome neighbours, and dispossessing them, annexed their territories to the communities, and thus acquired a very considerable addition of power. Several instances of this kind occur in the 11th, and the beginning of the 12th century. As increasing power enlarged the prospects of ambition, the cities proceeded to attack several barons at a greater distance, and compelled them to become members of their communities; to take the oath of fidelity to their magistrates, to subject their lands to all burdens and taxes imposed by common consent, to defend the communities against all their enemies, and to reside within the respective cities during a specified time in each year. This state, into which some nobles were compelled to enter, others embraced from choice, with a view to their security and credit. Accordingly they voluntarily became citizens of the towns to which their lands were most contiguous, and, abandoning their ancient castles, took up their residence in the cities, at least for some part of the year. This privilege was deemed so important, that not only laymen, but ecclesiastics of the highest rank, condescended to be adopted as members of the great communities, in hopes of enjoying the safety and dignity which that conferred. Hence cities not only became more populous, but were filled with inhabitants of better rank; and a custom which still subsists in Italy, was then introduced, that all families of distinction reside more constantly in the great towns than is usual in other parts of Europe.

Whilst cities were thus acquiring new dignity by the accession of such citizens, they became more solicitous to preserve their liberty and independence. The emperors, as sovereigns, had anciently a palace in almost every great city of Italy; in which they occasionally resided, and at this time the troops that accompanied them were quartered in the houses of the citizens. This, however, they deemed both ignominious and dangerous, and they combined to resist and abolish the practice. With this view they required the emperors to erect them in the suburbs. By degrees these encroachments of the Italian cities alarmed the emperors, and schemes were meditated for restraining them. In this enterprise Frederick Barbarossa engaged with great ardour. Upon this the free cities of Italy joined together in a general league, and stood in their defence; and after a long contest, carried on with alternate success, a solemn treaty of peace was concluded at Constance, A. D. 1183, by which all the privileges and immunities granted by former emperors to the principal cities of Italy were confirmed and ratified. This treaty secured very important privileges to the confederate cities; and though a considerable degree of authority and jurisdiction was reserved by it to the empire, yet the cities persevered so vigorously in their efforts for extending their immunities, and they enjoyed such favourable conjunctures for this purpose, that, before the conclusion of the 13th century, most of the great cities in Italy had shaken off all marks of subjection to the empire, and were become independent sovereign republics.

This innovation on the part of cities was not long known in Italy, before it made its way into France, and also into other countries of Europe, from A. D. 1108 to A. D. 1137. In less than two centuries, servitude was abolished in most of the towns of France, and they became free corporations, instead of dependent villages, without jurisdiction or privileges. Much about the same period, the great cities in Germany began to acquire like immunities, and laid the foundation of their subsequent liberty and independence. The ancient Germans, it should be recollected, had no cities. They considered it as a badge of servitude to be obliged to inhabit a city surrounded with walls. (Tacit. de Mor. Germ. c. 16. Id. Histor. l. iv. c. 64.) The Romans built several cities of note on the banks of the Rhine; but in all the extensive countries from that river to the coasts of the Baltic, there was hardly one city previous to the 9th century of the Christian æra. Under Charlemagne, and the emperors of his family, several cities were founded in Germany, and men became accustomed to associate and live together in one place. Charlemagne founded two archbishoprics and nine bishoprics in the most considerable towns of Germany. His successors increased

increased

increafed their number; and as bifhops fixed their refidence in thefe cities, and performed religious functions there, many people were thus induced to fettle in them. However, Henry, furnamed the Fowler, who began his reign A. D. 920, muft be confidered as the great founder of cities in Germany; which he eftablifhed in order to counteract the incurfions of the Hungarians and other barbarous people. He thus encouraged his fubjects to fettle in thefe cities, furrounded with walls and towers, and by enjoining or perfuading fome of the nobility to fix their refidence in the towns, he rendered the condition of citizens more honourable than it had formerly been. From this period the number of cities continued to increafe, and thus became more populous and more wealthy. Various circumftances contributed to their increafe. The eftablifhment of bifhoprics, and alfo the building of cathedrals, induced many people to fettle there. Befides, it became the cuftom to hold councils and courts of judicature of every kind, ecclefiaftical as well as civil, in cities. In the 11th century many flaves were enfranchifed, and many of them fettled in cities. Several mines were difcovered and wrought in different provinces, which, drawing together a great concourfe of people, gave rife to feveral cities. In the 13th century the cities began to form leagues for their mutual defence, and for repreffing the diforders occafioned by the private wars among the barons, as well as by their exactions. This rendered the condition of thofe who inhabited cities more fecure than that of any other order of men, and allured many to become members of their communities.

Although the cities of Germany did not acquire liberty at fo early a period as thofe in France, they extended their privileges much farther. All the imperial and free cities, of which the number is confiderable, acquired the full right of being *immediate, i. e.* of being fubject to the empire alone, and poffeffing, within their own precincts, all the rights of complete and independent fovereignty. The practice of eftablifhing cities, which was adopted in Italy, France, and Germany, fpread quickly over other parts of Europe, and prevailed in Spain, England, Scotland, and all the other feudal kingdoms. It appears from Mariana, that in 1350, 18 cities had obtained a feat in the Cortes of Caftile. In Aragon cities feem to have acquired at an early period extenfive immunities, together with a fhare in the legiflature. In 1118, the citizens of Saragoffa had not only obtained political liberty, but were declared to be of equal rank with the nobles of the fecond clafs; and many other immunities were conferred upon them. In England, as we have already obferved, the eftablifhment of communities or corporations was pofterior to the Conqueft; and the practice was borrowed from France. Lord Lyttelton, however, fuggefts, in his "Hiftory of Henry II. (vol. ii. p. 317.) that fome of the towns in England were formed into corporations under the Saxon kings, and that the charters granted by the kings of the Norman race, were not charters of enfranchifement from a ftate of flavery, but a confirmation of privileges which they already enjoyed. However this be, the Englifh cities were very inconfiderable in the 12th century.

The inftitution of cities was interefting and beneficial. Its influence on government, as well as manners, was no lefs extenfive than falutary. It was the means of releafing a great body of the people from flavery, and of promoting the interefts of general liberty and of general fecurity. It contributed alfo to the revival of a fpirit of induftry; to the profperity of commerce; to the increafe of population; to the diffufion of wealth, and to a greater degree of refinement in the manners, and in the habits of life. Together with this improvement in manners, a more regular kind of government and police was introduced, ftatutes and regulations became neceffary with the increafing populoufnefs of cities, and all became fenfible that their common fafety depended on obferving them with exactnefs, and on punifhing fuch as violated them with promptitude and vigour. Laws and fubordination, as well as polifhed manners, took their rife in cities, and infenfibly diffufed themfelves through the reft of the fociety. When the inhabitants of cities had obtained perfonal freedom and municipal jurifdiction, they foon acquired civil liberty and political power. In procefs of time the reprefentatives of cities gained a place in the legiflature; and this event had great influence on the form and genius of government. It tempered the rigour of ariftocratical oppreffion, with a proper mixture of popular liberty; it fecured to the great body of the people, hitherto unreprefented, active and powerful guardians of their rights and privileges; and it eftablifhed an intermediate power between the king and nobles, to which each had recourfe alternately, and which at fome times oppofed the ufurpations of the former, and on other occafions checked the encroachments of the latter. After the inhabitants of towns had been declared free by the charters of communities, the other part of the people which refided in the country, and was employed in agriculture, began to recover liberty by enfranchifment. Accordingly, the enfranchifment of flaves became more frequent in France, Italy, Germany, and England. In our own country more efpecially, as the fpirit of liberty gained ground, the very name and idea of perfonal fervitude, without any formal interpofition of the legiflature to prohibit it, were totally banifhed. Upon the whole we may obferve, with Dr. Robertfon, that the eftablifhment of communities contributed more perhaps than any other caufe, to introduce regular government, police, and arts, and to diffufe them over Europe. Hift. Ch. V. vol. i. *paffim.* See CHARTERS *of Community.*

CITY, CIVITAS, in fpeaking of antiquity, fignifies a ftate, or people, with all its dependencies, conftituting a particular republic. Such are ftill feveral cities of the empire, and the Swifs cantons.

Though the ancient Gauls were, in effect, only one nation; they were yet divided into feveral people, which formed as may different ftates: or, to fpeak with Cæfar, as many different *civitates, cities.* Befides that each city had its peculiar affemblies, it fent deputies too, from time to time, to the general affemblies held on affairs relating to their common intereft.

CITY is particularly ufed to exprefs the heart of the place. At Paris they have the *city* and the *univerfity;* at London we have the *city* and the *fuburbs.*

It has been obferved that large cities are more liable than other places to peftilential and putrid diforders, which is owing to the ftagnation and corruption of the air. This is always the cafe in thofe which are low and unprovided with common fewers; where the ftreets are narrow and foul, the houfes dirty, water fcarce, and jails and hofpitals crowded; alfo, when in fickly times the burials are within the walls, or when dead animals and offals are left to rot in the kennels, or on dunghills; when drains are not provided to carry off any large body of ftagnating water in the neighbourhood; when flefh-meats make the greateft part of the diet, without a proper mixture of greens, bread, wine, or fermented liquors; from the ufe of old mouldy grain. In proportion to the number of thefe and the like caufes concurring, a city will be more or lefs fubject to peftilential difeafes, or to receive the leaven of the true plague, brought into it by any merchandize. An excellent writer emphatically calls them the graves of the human ſpecies. See *Bills of* MORTALITY.

However, as great cities furniſh many materials for vitiating the air, they likewiſe afford two conſiderable antidotes; the firſt ariſes from the circulation of the air, by means of the conſtant motion of people and carriages, and of the draughts made by fires; the other depends on the great quantity of an acid produced by fuel, the ſtrongeſt reſiſter of putrefaction.

CIVES, in *Botany* and *Gardening.* See ALLIUM.

CIVET, a kind of perfume, bearing the name of the animal whence it is taken.

The word comes from the Arabic *zibet* or *zebed, ſcum, froth.*

The animal, commonly known by the name of the *civet*, or *civet-cat*, is the "Viverra civetta" of Linnæus, the "Meles faſciis et maculis albis, nigris et rufeſcentibus variegata" of Briſſon, the "felis zibethi" of Geſner, the "civette" of Buffon, and the "aſh-coloured weeſel, ſpotted with black, with cheſnut-coloured mane, and duſky tail ſpotted towards the baſe" of Dr. Shaw. Its general length, from noſe to tail, is ſomewhat more than two feet, and the tail meaſures 14 inches. The ground-colour of the body is yellowiſh aſh grey, marked with large blackiſh or duſky ſpots, diſpoſed in longitudinal rows on each ſide, with ſometimes a tinge of ferruginous; the hair is coarſe, and along the top of the back ſtands up, forming a ſort of mane; the head is of a lengthened or ſharpiſh form; with ſhort rounded ears; the eyes are of a bright ſky-blue; the tip of the noſe black; the ſides of the face, chin, breaſt, legs, and feet are black; the remainder of the face, and part of the ſides of the neck, are of a yellowiſh-white; from each ear are three black ſtripes, terminating at the throat and ſhoulders; the tail is generally black, but ſometimes marked with pale or whitiſh ſpots on each ſide of the baſe. Some naturaliſts, and particularly Belon, will have it to be the ſame with the hyæna of the ancients, and calls it "hyæna odorifera." But Buffon obſerves, that it has nothing in common with the hyæna, except the fiſſure or ſac, under the tail, and the mane along the neck and ſpine. It differs from the hyæna in the figure and ſize of the body, being one-half ſmaller. Its ears are ſhort, and covered with hair, while thoſe of the hyæna are long and naked. Beſides, it has ſhorter limbs, and five toes on each foot; but the legs of the hyæna are long, and it has only four toes on each foot. Neither does the civet dig the earth in queſt of dead bodies. Theſe animals, therefore, are eaſily diſtinguiſhed. The civet is an animal of a wild diſpoſition, and lives in the uſual manner of others of this genus, preying on birds, the ſmaller quadrupeds, &c. It is a native of ſeveral parts of Africa and India; but not of America, as ſome have erroneouſly aſſerted; though it has been tranſported thither from the Philippine iſlands, and the coaſt of Guinea. This animal, as well as the "zibet," though originally natives of the warm climates of Africa and Aſia, are capable of ſubſiſting in temperate and even in cold countries, provided they are defended from the injuries of the weather, and fed with ſucculent nouriſhment. Numbers of them are kept in Holland for the ſake of procuring and ſelling the perfume which they yield, called *civet*, and ſometimes erroneouſly confounded with muſk. There is a conſiderable traffic of civet from Baſſora, Calicut, and other places, where the animal that produces it is bred; though great part of the civet among us is furniſhed by the Dutch, who rear a conſiderable number of the animals. That which is obtained from Amſterdam is preferred to that which comes from the Levant or India, becauſe the latter is generally leſs pure. That brought from Guinea would be the beſt, if the negroes, as well as the Indians and Levanters, did not adulterate it with the juices of plants, or with labdanum, ſtorax, and other balſamic and odoriferous drugs. This perfume is gathered from time to time; and ſtill abounds in proportion as the animal is fed. Before any of theſe animals were ſeen in Europe, or it had been obſerved how the perfume had been gathered, the common opinion, founded on the relations of travellers, was, that it was the ſweat of that animal, when irritated and provoked into rage. To this effect, it was ſaid, that the animal was incloſed in an iron cage, and, after having been a long time beaten with rods, they gathered with a ſpoon, through the bars of the cage, and between the thighs of the animal, the ſweat or foam, which the rage and agitation had produced; and that, without this precaution, the animal would yield no perfume at all; which is undoubtedly falſe. This ſubſtance is a ſecretion formed in a large double glandular receptacle, ſituated at ſome little diſtance beneath the tail, and which the animal empties ſpontaneouſly. When the civet-cats are kept in a ſtate of confinement (as is uſually the caſe with the perfumers at Amſterdam and other places), they are placed, from time to time, in ſtrong wooden cages or receptacles, ſo conſtructed as to prevent the creature from turning round and biting the perſon employed in collecting the ſecreted ſubſtance; this operation is ſaid to be generally performed twice a week, and is done by ſcraping out the civet with a ſmall ſpatula or ſpoon. The ſubſtance is of a yellowiſh colour, and of the conſiſtence of an unguent; of an extremely ſtrong, and even unpleaſant odour when freſh, ſo as ſometimes to cauſe giddineſs and head-ach; but becomes more agreeable by keeping, though this is denied by the French academicians of the laſt century; the quantity obtained each time amounts to about a dram. The quantity ſupplied depends much on the quality of the nouriſhment, and the appetite of the animal, which always produces more in proportion to the goodneſs of its food. Boiled fleſh, eggs, rice, ſmall animals, birds, young poultry, and eſpecially fiſhes, are the beſt kinds of food, and they ought to be ſo varied as to preſerve the health and excite the appetite. He requires very little water; and though he drinks ſeldom, he diſcharges urine frequently; and in this operation, the male is not to be diſtinguiſhed from the female. When the ſecreted ſubſtance becomes incommodious to the animal on account of its quantity, or when the reſervoirs are too full, it is provided with proper muſcles for ſqueezing it out. The perfume of the animals is ſo ſtrong that it infects all parts of the body: the hair and the ſkin are ſo thoroughly penetrated with this odour, that they retain it long after death; and, during life, it is ſo violent as to be quite inſupportable, eſpecially if a perſon be ſhut up in the ſame apartment with the animal. When heated with rage, the odour becomes more highly exalted; and if the animal be tormented till he ſweats, the keeper collects the ſweat, which has likewiſe a ſtrong ſcent, and ſerves for adulterating,

adulterating, or, at leaſt, augmenting the quantity of the perfume.

Beſides the India and Dutch civet, there is alſo a civet from Braſil, Guinea, &c. like that of India.

There is another animal, *viz.* the "Viverra zibetha," (which ſee) or zibet of Buffon, that agrees in diſpoſition and manners with that above deſcribed; and which yields a ſecretion of perfume that is collected in the ſame manner.

Civet, though an article in the more ancient Materia Medica, and though ſtill employed by the oriental phyſicians, is uſed with us chiefly in perfumes. It has a very fragrant ſmell, and a ſub-acrid taſte; it unites readily with oils, both expreſſed and diſtilled; in watery or ſpirituous menſtrua, it does not diſſolve, but impregnates the fluids ſtrongly with its odour. It may, however, be made to unite with, or be ſoluble in water, by means of rubbing with mucilages. Civet has been ſometimes uſed medicinally in a thickneſs of hearing ariſing from cold; in which caſe, a grain or two being put in a little cotton or wool, and the ears ſtopped with it, is ſometimes of ſervice. Shaw's Zool. vol. i. part 2. Buffon by Smelly, vol. v.

CIVIC Crown, among the Romans, was a garland made of oak-leaves and acorns, or of ground oak, and was given as a reward to ſuch as had ſaved a citizen's life in battle, or reſcued him after being taken priſoner. This crown was highly eſteemed; and was given as an honour to Auguſtus Cæſar, who on that occaſion cauſed coins to be ſtruck, inſcribed OB CIVES SERVATOS. It was alſo given to Cicero, after his diſcovery of Catiline's conſpiracy. See Crown.

CIVIDAD das Palmas, in *Geography*, a ſea-port town of the Grand Canary iſland, called alſo *Canary*, which ſee.

Cividad *Real.* See Chiapa.—Alſo, the capital of the province of Guaira, in the eaſtern diviſion of Paraguay.—Alſo, a town of Spain, and capital of La Mancha, famous for a manufacture of leather gloves. It has three churches, ſeven convents, and three hoſpitals; 7 miles from Toledo.

Cividad *de los Reyes*, a town of South America, in the country of Terra Firma, and province of St. Martha. The heat is moderated in ſummer by the eaſt wind; but frequent rains and chilling blaſts from the mountains produce coughs and fevers. The adjacent land is fertile, and abounds in paſtures. The inhabitants are numerous, warlike, and hitherto unſubdued.

Cividad *del Rey Felippe*, a town built in 1585 on the continent of South America, near the ſtraits of Maghellan, but ſoon abandoned.

Cividad *del Rio del St. Pedro*, a town of South America, in Braſil, ſituated at the mouth of the river St. Pedro. S. lat. 32°. W. long. 34° 15′.

Cividad *Rodrigo*, a town of Spain in Leon, ſeated on the river Aguada, the ſee of a biſhop, ſuffragan of Compoſtella; built by Ferdinand II. as a rampart againſt Portugal, from which it is about 8 miles diſtant; 45 miles S.S.W. from Salamanca. N. lat. 40° 52′. W. long. 6° 15′ 24″.

CIVIERE, a ſmall hand-barrow carried by two men, and much uſed in the artillery, particularly at mortar batteries.

CIVIL, Civilis, in its general ſenſe, denotes ſomething that regards the policy, public good, or peace of the citizens, or ſubjects of a ſtate. In this ſenſe we ſay, civil government, civil law, civil rights, civil war, &c.

Civil, in a *Legal Senſe*, is alſo applied to the ordinary procedure in an action relating to ſome pecuniary matter, or intereſt. In which ſenſe it is oppoſed to criminal.

Civil *Action.* See Action.

Civil *Architecture.* The hiſtory of architecture, in a general ſenſe, would require an account of all the modes of building practiſed at different times among the various nations of the earth; but as it is not conſiſtent with the plan of the preſent work to include in one treatiſe the entire conſideration of any ſcience, we ſhall follow the ſubdiviſion which the ſubject naturally preſents, and treat of architecture as an uſeful and as a fine art. The former has been already conſidered under the article Building; and the preſent article will be devoted to the inveſtigation of the latter, in which we ſhall confine our attention to the architecture of Greece, and its imitators, the only ſtyle of building which, proceeding on a reaſoned ſyſtem of imitation, and regular proportions, has a title to be ranked among the fine arts.

Greece, which, after the decline of Egypt, became ſo eminent, pretended to no high antiquity, or remote origin. Her hiſtory reaches not many centuries back from that era which beheld her flouriſhing in arts and letters beyond all that the world had known before. The perſon to whom ſhe attributes the invention of the common conveniencies of life, exiſted long after Egypt had become a powerful and enlightened kingdom. Prometheus, whoſe ſuppoſed age is not more than 1600 years prior to the Chriſtian epoche, is introduced by Æſchylus, in his tragedy, as enumerating the various benefits which he had conferred upon mankind: amongſt the reſt he taught them (he ſays) to conſtruct houſes with bricks and timber; for till then they knew nothing of building, but dwelt in holes and caverns.

This perſonage (like many others to whom the invention of uſeful arts is attributed) is probably nothing more than factitious: or perhaps the Greeks might deſign, by this appellation, to preſerve the character, when they had forgotten the name, of their benefactors. Prometheus, which ſignifies prudence, is a term juſtly applicable to the ſagacity of all thoſe who made the diſcoveries that are aſcribed to that perſon. And the age which is aſſigned to him, the time when he is ſuppoſed to have lived, whatever be repreſented under his ſtory, will determine the period which the Greeks acknowledge for the origin of their civilization.

The priority of Homer to all other Grecian authors, his extenſive acquaintance with the arts, and his faithful and animated deſcription of the manners of his age, impart a ſingular value to whatever information he conveys upon thoſe topics. It may be amuſing to collect, from his poems, what was the ſtate of architecture at his time in that country, where it was deſtined, within a few generations afterwards, to attain to a pitch of excellence unequalled either in ancient or modern annals.

The houſes (the only ſpecies of edifices of which Homer has given any detail) had a court in front, which was fenced around, ſometimes with ſtone. An altar to the ſupreme deity (Jupiter) ſtood in the middle of the court, and one or more ſides of it were ornamented with a portico, where it was a cuſtom to lodge the gueſts. Dogs were kept here for a guard to the houſe; and ſometimes pictures of them were placed here: here alſo were the ſtables. This particular, *viz.* the ſituation of the ſtables, was obſerved by the Greeks in later ages, when, as Vitruvius relates, they built their houſes without any court in front. In the houſe itſelf the ground-rooms were lofty, and ſupported either by one or more columns. The upper ſtory was appropriated to the women; who were not, however, in that age, ſecluded from the common apartment, or the company of ſtrangers. We learn that the roofs of the houſes were flat, by an accident which befel one of the companions of Ulyſſes; who having got intoxicated at the houſe of Circé, fell from the roof and was killed. From time immemorial the ſame kind of roofs has been common in the ſouthern and eaſtern countries, and the ſame kind of accidents has attended them: ſo that the

Jews had a law reſpecting roofs, Deut. c. 22. v. 8, by which they were obliged to ſurround the top of their houſes with a baluſtrade, to prevent men from falling off.

In the Iliad few particulars of architecture are to be found. We read there little more than that Priam's palace contained 50 chambers; and that Paris lived in a ſeparate houſe adjoining, which he had built for himſelf with the aſſiſtance of ſome architects. It had a hall, a chamber, and a court. But it is in the Odyſſey, that intereſting narrative, and pleaſing delineation of manners, that the architecture of Homer's age is to be traced; and eſpecially in the palace (if it may be ſo called) of Ulyſſes. This edifice was diſtinguiſhed from all the reſt, in his town of Ithaca, by having the wall of the court built of ſtone with θριγκοι (ſome crowning ornament), and a gate with folding doors. There appears to have been but one room or hall for the reception of the company; the entrance to which was from the court. It muſt have been of great dimenſions; for it was not only large enough to entertain above 50 perſons at ſeparate tables, but alſo ſerved for ſeveral other purpoſes. The columns (if they were more than one), that ſtood within it, ſeem to have been as much for uſe as ornament. They were lofty; and the room probably roſe to the height of two ſtories. The floor was paved with ſtone; but rather ſunk than raiſed above the level of the natural ſoil; or, at leaſt, it was lower than the ſtone threſhold at its entrance. Two ſtaircaſes led from the hall; one to the roof, as it ſhould ſeem, and the other to certain ſtore-rooms, whither Ulyſſes conveyed away the armour from the hall, leſt the ſuitors ſhould avail themſelves of it when he came to attack them. The windows muſt have been at a great height from the floor; for the ſuitors when they were aſſaulted and ſaw themſelves without any means of defence, neither attempted to eſcape out of them, nor to call for aſſiſtance through them; notwithſtanding that they propoſed to raiſe the town in their behalf; but they knew no other way to do this than by getting to the roof, and the ſtaircaſe which led to that was guarded againſt them. On the night before they were ſlain they entertained themſelves with muſic and dancing; when the hall was lighted up by fires made upon three moveable hearths or braziers; and during that time Ulyſſes, in the character and dreſs of a beggar, attended in the room, to ſupply the cleft wood which was burnt upon them for a light. The total neglect of cleanlineſs is a feature which marks, as ſtrongly as any, the condition, perhaps the riot and licentiouſneſs, of Ulyſſes' houſe. For to omit other particulars, ſuch as the dunghill lying by the path way from the court-gate to the hall-door, the hall itſelf was the place where they killed, or at leaſt cut up and dreſt their beaſts; and they held the feaſts in the midſt of the ſkins and offal. When, upon the diſcovery of Ulyſſes, the ſuitors were incloſed and deſtroyed in the hall, the herald, who was among them, ſaved his life by hiding himſelf under a ſkin, that was newly taken off and left there; and when one of the ſuitors deſigned to inſult Ulyſſes while he was ſitting at meat near Telemachus, he found a bullock's foot lying cloſe by him, which he took up and threw at his head.

Within about four centuries from this era of coarſe manners in Greece did the ſame people arrive at the higheſt excellence in the polite arts that had ever been attained. And though that ſpace of time may appear ſufficiently long for the acquiſition of any ſcience, according to modern ideas, it is to be remembered that thoſe ages wanted our means of communicating knowledge; for writing and books were then almoſt unknown. By what ſteps they made ſuch a progreſs is not related; but that the varieties in architecture, the Ionic and Corinthian orders and all the ornaments, were invented within the period, is juſtly inferred from Homer's ſilence concerning them. Had architecture, at that time, been diſtinguiſhed by its ſeveral orders, or decorated with an entablature of carved work, we ſhould have heard from the Grecian, as we have from our own bard, *of Doric frize and cornice;* for he evidently takes a delight in deſcribing all the arts which then exiſted, and he was fond of diſplaying his learning.

The progreſs of improvement in Grecian architecture appears to have occupied a period of about three centuries, from the age of Solon and Pythagoras beginning with the year, before Chriſt, 600, when the temples of Jupiter, at Olympia and in the capitol of Rome, thoſe at Samos, Priene, Epheſus, and Magneſia, were begun, to the time when, under the adminiſtration of Pericles, the ornamental ſtyle of Grecian architecture attained its utmoſt beauty and perfection, in the temple of Minerva in the acropolis of Athens, built after the model of that of Jupiter at Olympia, and finally concluding this firſt period with the completion of the temple of Diana at Epheſus, in the time of Alexander, which, as Pliny informs us, had been 220 years in building, one of the columns being the work of Scopas. The ancient temple of Minerva, at Tegea in Arcadia, having been deſtroyed, a ſecond edifice was erected under the direction of Scopas, far exceeding in ſplendour and magnificence every building of the kind in the Peloponneſus. In this ſtructure the three Grecian orders of architecture were employed. Within the encloſure were galleries ſupported by Doric and Corinthian columns ſurrounding the hypæthros or open area of the cella. On the outſide of the temple were porticos of the Ionic order. The facades were enriched with ſculpture. (Pauſanias, l. viii.) To theſe examples may be added the temples in Sicily, as far as Gelo or Hiero may have contributed to their conſtruction, though many of them, as well as thoſe of Pæſtum, may poſſibly have had an earlier date.

Of all the phenomena in the political hiſtory of mankind, there is none more curious and wonderful than the great comparative degree of ſtrength and power, both internal and external, acquired by thoſe little ſtates whoſe only territory was a petty iſland, a narrow iſthmus, or a rocky promontory, from which they ſent out their piratical fleets to every part of the Mediterranean, and planted colonies on all its coaſts, in defiance of the proud monarchs who ruled the extenſive and populous plains of Aſia and Egypt, or the rude and hardy barbarians who inhabited the no leſs fertile regions of Sicily and Italy. Not only the leading ſtates, ſuch as Athens, Corinth, and Syracuſe, but Pæſtum, Segeſta, and Selinus, little obſcure republics, whoſe names alone can be gleaned from hiſtory by the diligence of the antiquary, have erected public works which would be a conſiderable enterprize for the greateſt nations of modern times. The portico of the great temple of Selinus in Sicily, which is one of ſix ſtill remaining, though proſtrate and in ruins on the ſite of that city, conſiſted of a double periſtile of eight columns in front and ſeventeen in depth, each of which was ten feet diameter and fifty feet high.

In conſidering the buildings of antiquity, and particularly of Greece, the firſt circumſtance that ſtrikes us is their extreme ſimplicity and even uniformity of plan; the temples of Greece were invariably quadrilateral buildings, differing only in ſize, number of columns, and diſpoſitions of the porticos, which either ornamented the front alone or ſurrounded every ſide. Prior to the Macedonian conqueſt all the temples of Greece and its colonies, in Sicily and Italy, appear to have been of one order, the Doric, and one general form, though ſlightly varied in particular parts, as oc-

cational

cafional convenience or local fafhion might chance to require. Their general form was an oblong fquare of fix columns by thirteen, or eight by feventeen, inclofing a walled cell, fmall in proportion, which in fome inftances appears to have been left open to the fky, and in others covered by the roof which protected the whole building.

The fyftem of Grecian architecture is founded on the fimple principles of wooden conftruction; a quadrangular area is furrounded with trunks of trees placed perpendicularly with regular intervals; thefe fupport lintels, upon which reft the beams of the ceiling, and an inclined roof covers the whole. Such was the model in which, when touched by the hand of tafte, the poft and lintel were transmuted into the column and entablature, and the wooden hut into the temple.

It appears probable that the earlieft Greek temples were really of wood, fince fo many of them were confumed during the invafion of Xerxes; and that large and magnificent edifices were fometimes compofed principally of this material, is rendered evident by the example of the temple of Jerufalem, which was furrounded with columns of cedar. But builders foon adopted the more noble and durable material of ftone, and though the general fyftem of architecture was already eftablifhed, its forms received fome modification by being thus, as it were, tranflated into a new language.

A wooden lintel, from its fibrous texture, poffeffing confiderable tenacity and ftrength, in proportion to its weight, it was practicable to form very wide intercolumniation; thus we are told by Vitruvius, that the ancient Tufcan temples were conftructed with wooden architraves. Stone, on the other hand, of a granular compofition, and of great fpecific gravity, would break by its own weight in a bearing where a timber beam would be perfectly fecure. When, therefore, porticos were erected of ftone, it was neceffary, in order to enfure folidity, to contract the diftance between the columns to very narrow limits. A wooden edifice, never fecure from the injuries of accident or violence, prefented no motive for any great folidity in its conftruction. But in ftone it is poffible, as the energetic induftry of the ancient Egyptians has fhewn, to defy the injuries of time, and almoft the violences of rapine. The architect who builds in ftone may build for eternity, and this idea will give a motive for that grand and maffy folidity fo effential to the fublime of architecture. Thefe circumftances led to the perfection of the Grecian ftyle; the original model fecured fimplicity of form and conftruction, while a fuperior material preferved it from the meagrenefs attendant on wooden building.

Thus arofe the Doric, or, as it might be emphatically called, the Grecian order, the firft born of architecture; a compofition which bears the authentic and characteriftic marks of its legitimate origin in wooden conftruction transferred to ftone.

In contemplating a capital example of this order, as, for inftance, the Parthenon of Athens, how is our admiration excited at this nobleft as well as earlieft invention of the building art. What robuft folidity in the column—what maffy grandeur in the entablature—what harmony in its fimplicity; not deftitute of ornament, but poffeffing that ornament alone with which tafte refines and dignifies the conceptions of vigorous genius. No foliage adds a vain and meretricious decoration, but the frieze bears the achievements of heroes, while every part, confiftent in itfelf, and bearing a juft relation to every other part, contributes to that harmonious effect which maintains the power of firft impreffions and effects with increafing admiration in the intelligent obferver. Other orders have elegance, have magnificence, but fublimity is the property of the Doric alone.

Fluting the fhafts of a column is a practice never omitted in any great and finifhed Grecian work, and which appears to be mentioned by Homer, who, in defcribing the column of Ulyffes' hall, ufes the expreffion δουροδοχη, or *fpear-holder*, which we conceive can only mean flutes or channels cut in the fhaft. It therefore feems probable that this ornament had fome relation to the original type; perhaps the furrowed trunk might fuggeft the idea; it is, however, a beautiful decoration, which is applied with equal happinefs to break the otherwife heavy mafs of a Doric fhaft, or, in the other orders, to obviate an inconfiftent plainnefs. The invention of the Ionic and Corinthian orders enlarged the bounds of architectural compofition, and completed its powers of expreffion.

The Ionic order was, doubtlefs, invented in that country whofe name it bears, and where its beft models are ftill to be found. Vitruvius fuppofes this order to have been founded upon the imitation of the female form, as he alfo fuppofes the proportions of the Doric order to have been fettled upon thofe of men. The Greeks in Ionia having formed the Doric order according to the proportions of a man, followed the fame traces to obtain a new order that fhould imitate the gracefulnefs of women, and to that end they made a flenderer column whofe thicknefs was only one-eighth part of its height. To this order they gave a bafe by which they defigned to reprefent a fhoe, and the capital had a curling ornament, called a volute, faid to refemble the treffes of the hair dropping to the right and left. The channels and flutings of the fhaft were the plaits of the matron's garment. Thus arofe the invention of two orders, one of a mafculine appearance and unadorned, the other imitating the fine proportions of the female fhape.

The hiftory of the origin of the Corinthian order, which might poffibly be contrived either to give an intereft to the invention or to difguife the fource from whence it came, though fo often repeated and fo well known, may, neverthelefs, be here told once more as a pleafing anecdote of ancient manners. A young maiden of Corinth having died, her mother or nurfe collected in a bafket the toys which fhe had been fond of while alive, and carried them to her grave, where fhe left the bafket covered with a tile to preferve its contents from the weather. The bafket happened to be fet upon the root of an acanthus. The plant being thus depreffed in the middle, its leaves and ftalk fpread outwards, and grew up around the fides of the bafket till they were bent down by the tile, which lay projecting over its top.

At that time Callimachus, the fculptor, chanced to pafs by the grave, and being pleafed with the agreeable appearance of the foliage, and novelty of the form, he converted it to the purpofes of architecture; and having made fome columns of a more delicate proportion than had been ufed before, he adopted the bafket and leaves of the acanthus for the capital; and thus eftablifhed the fymmetry and ornaments of the Corinthian order.

The Egyptian capitals, which are ftill to be feen decorated with palm and other leaves, throw great doubt upon this ftory. Yet Callimachus might claim great merit from the Corinthian capital, and even fome fhare of the invention. He might be the firft who conceived the idea of fubftituting the leaf of the acanthus; and certainly the capital was improved in Greece, efpecially in the happy adjuftment of its ftalks and foliage, and this too was probably due to Callimachus.

machus. It is unfortunate for the fame of that architect, that no relic of this order exifts in the city which gave name to it.

About the fame time that Grecian architecture was rifing to eminence, the Tufcans, by whofe name one of the five orders is ftill diftinguifhed, began to fignalize themfelves in Italy by their fuperior fkill in building. The tomb of Porfenna, king of Etruria, which he founded in the city of Clufium, is recorded by Pliny (Nat. Hift. b. 36) as a wonderful, but idle, fpecimen of their art. Their works at Rome were lefs oftentatious, but much more important and ufeful. In that city they were employed in conftructing its walls of hewn ftone, and in raifing the Capitol. To them alfo muft be attributed the cloaca maxima, that extraordinary piece of architecture, which has always been ranked with the chief monuments of Roman greatnefs, and which remains to this day an object of admiration. Rome was fortified and adorned with thefe ftructures at an early period, while fhe was advancing to power and dominion under the government of her kings. The Tarquins, in whofe reigns thefe great works were undertaken, were of Tufcan origin.

But while a ftyle of grandeur was difplayed in the public edifices of that city, its private buildings were mean and poor. The life and manners of an ancient Roman citizen were not of a nature to difpofe him to the ftudy of architecture; and when the Gauls, in the 366th year of Rome, facked and burnt it, they deftroyed but a parcel of forry huts. Neither was the city after their departure rebuilt in any good or improved manner. Expedition alone feems to have been required, but order and propriety altogether neglected. For Livy afferts (b. 5.) that, without ftaying to have the ftreets fet out, every perfon feized upon the ground which he found vacant, fo that in many parts they built their houfes over the common fewers *(cloacæ)*; and that the public gave permiffion to dig ftones and cut timber at free coft, and fupplied roofing, that is fhingles, for all thofe who would give fecurity to complete their houfes within a year.

Their connection with Greece afterwards introduced the Romans to the knowledge of a more elegant ftile of architecture; and long before the period when Vitruvius compofed his treatife, they could boaft of many good architects, and fome authors upon the fubject. Of thefe, one of the earlieft and the moft eminent was Coffutius. This artift was engaged by king Antiochus about 200 years before the Chriftian æra, in the temple of Jupiter Olympus, which Pififtratus had begun; and then was feen the novel fpectacle of a Roman citizen conducting the architecture of the principal edifice in Athens.

We are not to conclude from hence that the art had fo far declined in Greece as to need the affiftance of foreigners; nor to eftimate its progrefs at Rome by the folitary inftance of Coffutius. The Greeks, who might efteem the age of Pericles as the period of their higheft excellence in architecture, about that time poffeffed three orders, either invented or improved by themfelves, which were refpectively applicable to every fpecies of building where ftrength, or elegance, or lightnefs was requifite. The fpoils of the eaft enabled them, under Alexander and his fucceffors, to increafe the number, and enrich the ftile, of their edifices; but the influx of that wealth was not fo abundant as to corrupt their tafte, or fupply the extravagancies of luxury; and architecture, among that people, underwent little or no change for the worfe. The Romans as yet cultivated few arts but that of war. Greece, and afterwards Afia, had the misfortune to fall under their dominion. The conqueft of the firft gave them fome tafte for the fine arts; the poffeffion of the latter furnifhed them with the means of indulgence. The return of Sylla from the Mithridatic war was the æra which was marked by the firft excefs of architecture in Rome. It was then that Scaurus, the fon-in-law of Sylla, raifed a temporary theatre, with fuch extravagance of decoration, that Pliny (Nat. Hift. b. 36.), who charges him as the firft who corrupted the Roman morals by luxury, affirms, "that the example was more pernicious to the city, than even the profcription of Sylla."

About fifty years before this period, an edifice of marble was erected in Rome, the earlieft of its kind; that edifice was a temple. The ufe of marble in private buildings was yet hardly known there; within a little time, however, it was introduced; firft, in door-cafes, then in columns: afterwards Mamurfa, an inferior officer in Julius Cæfar's army, incrufted his whole houfe with marble, and his example led the way to the ufe of marble in that manner with ftill greater profufion. But Mamurfa will appear moderate and fober if the expences and mode of his building be compared with thofe which took place under the emperors. The extent, the materials, the decorations of the Roman dwellings were then fuch as almoft exceed the limits of credibility. An author of the age of Tiberius fays, "The man thinks himfelf confined in his habitation now whofe houfe is not as large as the farm of Cincinnatus was," *(viz. 4 acres.)* This is not the language of one writer only; Pliny fays the like. "Thofe to whom the greatnefs of this empire is owing, had not fo much fpace for their farm, as fome now have for their cellars." The golden houfe of Nero was upon a fcale much larger ftill; it extended from the Palatine hill to the Efquiline. A defcription of it may be feen in the life of that emperor by Suetonius. When this pile of unparalleled extravagance was completed, Nero condefcended to exprefs his approbation of it, fo far as to fay, "that at laft he had got a houfe fit for a man to live in."

Auguftus diftinguifhed himfelf by his love for building. It was his boaft, that he had left a city of marble which he had found of brick. Inftigated by his example, and with a defire to pay him court, his relations, his wealthy fubjects, the governors of his provinces, princes, tributary or allied to him, all engaged in fome enterprize of architecture; and the general tranquillity of his reign was favourable to their operations; fo that not only in Rome and Italy, but alfo in the reft of his wide empire, grand and fumptuous edifices were erected. The colonies too which he fent out diffufed a knowledge of their architecture in the countries where they fettled; and Spain, Africa, and Germany exhibited to their rude inhabitants many fabrics in the Greek and Roman ftyle.

But none that courted the favour of Auguftus by extenfive and coftly buildings could, in that refpect, be compared with Herod the Great, king of Judea. The architectural defigns of this monarch were conceived and executed upon a fcale which furpaffed all others of his age. The re-building of the temple of Jerufalem, though a magnificent and wonderful undertaking, which occupied for eight years the labour of ten thoufand artificers, was yet but a fmall part of what he performed: other parts of his dominions were adorned by him, not merely with fingle edifices, but with entire cities. And if it be any excufe in an arbitrary governor, who burdens his people with heavy exactions, that they are expended liberally, it may be alleged in favour of Herod, that he raifed many ftructures of great fplendor and utility. The city and port of Cefarea, perhaps the chief of his enterprizes, was eminently fo. A full account of this, and a long catalogue of his other buildings, will be found in Jofephus, in the 16th book of his Antiquities of the Jews.

Whatever might be the efteem in which architects were held at Rome, there is reafon to think that the profeffion

was

was lucrative; a sufficient inducement to make practitioners. And if we should hesitate to give full credit to the assertion of Vitruvius, "that many professed to be architects who wanted sufficient knowledge to be masons," we may yet believe that many were so ignorant as to commit gross errors, and many so disingenuous, as to follow the caprices of their employer, rather than their own better judgment. The emperor Domitian, who was not of a temper to bear controul, engaged much in architecture; and the ruins of his superb palace are still remaining. The style of building is good, though not without evident faults. These, however, are not attributed so much to the architect, as to the caprice of the master, of whose bad taste this signal instance is upon record. Domitian had plundered the temple of Jupiter in Athens of some of its marble columns, and brought them to Rome, to be erected in the Capitol. Before they were set up, he cut them anew, and, by so doing, he destroyed their just proportion, and made them too slender. Such is the account and judgment of Plutarch. That author says farther, "Whoever should admire the costliness of the Capitol, and afterwards survey a portico in Domitian's palace, or a hall, or bath, or the apartments of his concubines, might apply what Epicharmus observed of a profuse man: 'You have not a taste, but an itch, for building; and, like Midas, you desire to make every thing about you gold and precious stones." (Life of Poplicola.)

Soon after the time of this emperor flourished Apollodorus, an architect, whose merits and unfortunate end entitle him to an honourable distinction among those of his profession.

He was a native of Damascus, who, by his eminent talents, recommended himself to the patronage of the emperor Trajan. Under his direction was constructed the celebrated bridge over the Danube; a work surpassing, in its kind, every thing that the architecture of Greece or Rome had produced. He executed many other considerable buildings, which were esteemed the best of their age; and in all the noble edifices that were raised by Trajan he was employed, or consulted. The stately column in Rome, which is yet standing entire, and distinguished by the name of Trajan's pillar, is a monument of the abilities of Apollodorus. But while he enjoyed the favour of the reigning emperor, he neglected to ingratiate himself with the presumptive heir. Adrian was not only fond of architecture, but also made some pretensions to a skill in that science, which, it is reported, Apollodorus was so impudent as to ridicule. When the empire devolved to Adrian, he built, after a design of his own, a temple dedicated to Rome and Virtue; whose statues, in a sitting posture, were placed within the cell. After the fabric was completed, he sent a representation of it to Apollodorus, as a tacit vindication of his architectural skill, and a proof of what he was able to perform. If the emperor was a bad architect, the architect was certainly no good courtier: for upon seeing the statues, sitting, as they were, in the temple, (which, it seems, wanted much of its due proportion in height) he said, if the goddesses should ever attempt to stand upon their feet they would assuredly break their heads against the ceiling. For this sarcasm, upon his disproportioned room, the emperor took that unjustifiable revenge, into which the excess of power may sometimes betray the mildest characters: Apollodorus was shortly after put to death.

But, notwithstanding this cruelty exercised against the best architect of his time, Adrian encouraged architecture equally with any of his predecessors, and certainly more than all those who succeeded him; nor does antiquity record any person whose buildings are so numerous and widely spread. Much of his reign was spent in visiting the various provinces of his empire: and throughout all the vast extent he raised monuments of architecture beyond the scale of ordinary edifices. Such, in the south of Egypt, was the city of Antinoopolis, and in the north of England, the wall of defence, 80 miles long; the ruins of which are still called after his name. He rebuilt, or repaired, various ancient cities. Athens was particularly distinguished by his liberality; where he, at length, completed the temple of Olympian Jupiter: more than 600 years had elapsed since the commencement of that renowned fabric. His villa at Tivoli (the extensive ruins of which are beheld with surprize), was the private retreat of this emperor, where he had combined, it is said, the different stiles of architecture of every country which he had visited: another instance of false taste, somewhat resembling what we have seen in England, by the introduction of Italian villas and Chinese bridges.

Here, if it be asked concerning these structures, so many, so great, and some of them so excellent, after whose designs they were built, or by whom they were conducted in Egypt, or Greece, or Italy, no satisfactory answer can be given. For while the munificence of the founder was recorded upon every frontispiece, and the name of Adrian was engraved upon the walls in so many places, that he was therefore denominated the wall-flower, the memory of one architect alone has been preserved. Of all those who were employed in the course of his reign, the name of Detrianus only is known, a proof of the little consideration that was then paid to the merit of architects.

The period of the Antonines, that golden age of Rome, produced some good works in architecture, of which the column yet standing, commonly called Antonine's, is one example. But that period was followed by such unsettled times, and desolating wars, that the arts never recovered from the confusion which then filled the empire.

Several succeeding emperors, as Severus Alexander, and particularly Dioclesian, engaged in building, and encouraged that art, which, however, speedily declined; and with the erection of the vast palace of the last mentioned prince at Spalatro, may be placed the final corruption of good architecture in the Western empire.

The removal of the seat of empire to Constantinople, taking place after the fine arts had received their mortal wound, that city was never illustrated by any public works of a pure and noble taste. The numerous structures of Justinian, which fill two volumes of description in Procopius, were more signalized by their richness than their proportions. The church of St. Sophia, though a grand effort of construction, is of barbarous architecture; the columns are of no established order or just proportion, and the outside is heavy and deformed by buttresses. The size and magnificence of the pile however commanded general admiration, and moved its founder, Justinian, upon a view of it when first completed, to exclaim, "that he had surpassed Solomon in his temple."

The Romans borrowed their architecture from Greece, but practised it with some peculiarities of manner and taste. In reviewing the most favoured period, and the best examples of Roman architecture, we find, in addition to the square plans of the Greeks, circular temples crowned with domes. The Corinthian was the favourite order at Rome, and as far as existing examples enable us to judge, the only order well understood and happily executed.

Thus practising the art as imitators, and further removed from the original type, with less severity of taste than the Greeks,

Greeks, the Romans formed a ſtile of magnificence which always poſſeſſed grandeur, and in their beſt works was combined with taſte and ſimplicity.

In conſidering the architecture of the period under contemplation (*viz.* of Greece and the beſt ages of Rome), one circumſtance remarkably attracts attention: that while ſuch is the variety of general and particular proportions of the forms of mouldings and members, that it is impoſſible to name any two examples of an order which agree in all reſpects, ſo that it is evident that the fancy of each artiſt directed theſe particulars: this exuberant fancy was ſo well reſtrained within reaſonable limits, that the whole collection of columns may be reſolved into three characteriſtic orders. Having three expreſſions, the ſtrong, the elegant, and the rich, they knew that this was all that architecture could ſay diſtinctly, and any intermediate ſhade would but weaken and confuſe her language. The character of the three orders being firmly eſtabliſhed, and clearly marked by ſtrong and general features, the details were ordered by the taſte of each practitioner, and in thoſe happy taſte was the birthright of almoſt every artiſt.

Of what nature were the ſyſtems of architecture of the Greeks, is a queſtion which naturally preſſes on curioſity, when we read of the written works of a long liſt of architects, whoſe names alone ſurvive, in the works of Vitruvius. The authority of the laſt mentioned author we are not inclined to rank very high, as his precepts are in general contradicted by thoſe extant; it may, however, be concluded from his manner of teaching the art, that the ancients proceeded on very different principles in the execution of the orders from the moderns. Thus Vitruvius directs us to vary the proportion of the members, according to the magnitude, ſituation, purpoſe, and other circumſtances of the building; while modern authors offer no rules of that kind, but preſcribe a certain fixed modulation of the parts of each order, to be uſed in all edifices, however circumſtanced; each author recommending ſuch as his peculiar ſtudies have cauſed to make a favourable impreſſion on his mind. The columns of areoſtyle temples, ſays Vitruvius, are eight diameters in height; thoſe of a diaſtyle intercolumniation, eight and a half; thoſe of ſyſtyle, nine and a half; of pycnoſtyle, ten; and of euſtyle, eight and a half; and this he directs without any modification for the different orders, though, in a ſubſequent part of the work, each order has its particular proportions aſſigned. The columns of public porticos are directed to be made half a diameter higher than thoſe in temples. That the ancients were alſo guided by minute optical conſiderations, is rendered probable by another paſſage reſpecting the diminution of columns, which is directed to be varied according to their altitude; thus, in a column of fifteen feet high, the diameter at the bottom is to be divided into ſix parts, and five given to the diameter at the top; if the column is from forty to fifty feet in height, the bottom diameter is to be divided into eight parts, and ſeven given to the top. Several intermediate proportions are mentioned, and if it is ſtill higher, the ſame principle is to be obſerved. The reaſon aſſigned for this is, that as a greater height cauſes the column to appear more diminiſhed, this appearance is to be corrected by an additional thickneſs, "beauty being the province of the eye, which, if not ſatisfied by the due proportion and augmentation of the members, correcting apparent deficiencies with proper additions, the aſpect will appear coarſe and diſpleaſing." The columns at the angles of the porticos are alſo directed to be made $\frac{1}{50}$ part of a diameter thicker than the others, becauſe they being more ſurrounded by the air will appear ſlenderer. This laſt practice is confirmed by the example of the temple of Minerva at Athens. In another part, Vitruvius gives an extraordinary direction, for which it is not eaſy to conceive a reaſon; that the columns of the ſide porticos of a temple ſhould be ſo placed, that the inner line of the ſhaft may be perpendicular, thus leaving all the diminution on the outſide. Columns thus formed are obſerved in the temple of Veſta at Tivoli, and perhaps in no other antique example.

In examining the progreſs of Roman building, it will be found that the introduction of arches operated an eſſential change in the forms and principles of architecture. This was the nobleſt improvement in the art of conſtruction, an invention which enabled man to bridle the mighty river, to raiſe in the ſkies the ſelf-balanced pile, and cover with the penſile vault the vaſt area of a temple of all the gods. But it may be doubted, whether the arch, though enlarging the powers of conſtruction, has not in fact been injurious to architecture, conſidered as a fine art. Grecian architecture, as it has been before obſerved, is founded on the forms and proceedings of wooden conſtruction, by which it acquired that ineſtimable ſimplicity which ſatisfies the judgment, and attracts, with increaſing admiration, the eye of taſte. The arch, on the other hand, may be ſaid to be the natural ſtyle of ſtone building, and thus this invention introduced a new and inconſiſtent principle of imitation, cauſing a confuſion of ideas both in ſyſtem and practice.

Some of the Roman buildings which exhibit marks of the deterioration of taſte alluded to are the following. Veſpaſian's temple of Peace, where a vault of ground arches, a figure in itſelf ugly and ignoble, is ſupported at the ſpringing of each groin by a ſingle Corinthian column, a ſupport as meagre and inadequate, in conſideration of the vault, as the application of it is contrary to ſyſtem. In the theatre of Marcellus, and the Coliſeum, we find ſeveral ſtories of arcades, while the intermediate piers are ornamented with engaged columns; thus the order, inſtead of forming an eſſential part of the conſtruction, is degraded to an idle and oſtentatious ornament. The Coliſeum, though impoſing, from its maſs and general ſimplicity of form, is very deficient in detail; and the theatre of Marcellus, though erected in the Auguſtan age, exhibits an example of the Doric order entirely deprived of its characteriſtic grandeur. The triumphal arches rather belong to ſculpture than architecture, and are therefore ſcarcely amenable to the rules of the latter art, otherwiſe they would be liable to ſimilar objections.

Together with the other fine arts, though not exactly with equal ſteps, architecture declined in the Roman empire; while the principles of the art were neglected or forgotten, the execution progreſſively barbarized. The palace of Diocleſian, at Spalatro, ſhews the ſenility of architecture; diſproportionate intercolumniations, pediments of which the horizontal cornices are ſuppreſſed; arches ſpringing immediately from columns, fantaſtic corbels, which, in defiance of the rules of ſolidity, ſupport columns; in theſe abuſes we trace the final degradation of Grecian architecture.

From this time commences the age of ſpoliation; impudent compilers of fragments, the barbarous builders of that period have but perpetuated their own ignominy. Conſtantine was the firſt of theſe depredators; he ruined the arch of Trajan to decorate his own with its appropriate ornaments, and erected his baſilicas with columns from the mauſoleum of Adrian. In this confuſion of ideas and practice, we may obſerve a certain characteriſtic ſtyle which marks the age. The builders, deficient in ſkill and ability, adopted a certain haſty and compendious mode of conſtruction, which influenced the forms of architecture. The columns which they had taken from other edifices, were placed with wide

wide intercolumniations; and therefore the original entablatures became ufelefs; to thefe were fubftituted arches, which, fpringing from the capitals, fupported the fuperftructures. The ornamental parts, being either wholly or in part the workmanfhip of former ages, prefented great incongruities, and difgraced the rude imitations of that period. Tafte in decoration and execution, was a quality wholly wanting; but yet, whether it were the example of antient edifices, the want of fancy, or real judgment, the plans and general forms preferved fomewhat of a grand and venerable fimplicity. The moft complete example remaining of this ftyle is to be feen at Rome, in the church of Saint Paul, without the walls; a building attributed to Conftantine, and which preferves fome antique columns of fingular beauty.

Thus the art lingered till the arrival of the Goths in Italy, when it may be faid to have expired by a violent death, efpecially in the repeated facking and burning of Rome, which had for fo many ages been the miftrefs of the univerfe.

Having thus traced the progrefs, decline, and extinction of Grecian architecture, our next tafk will be to defcribe its revival in modern times, leaving the ftyles of building prevalent in the middle ages to be treated of under the articles of NORMAN, SAXON, and GOTHIC *Architecture.*

Brunellefchi, born in 1377, may be regarded as the founder of modern architecture. After having exercifed his talents in various arts, and formed his mind by the ftudy of ancient authors, he undertook to revive the maxims of ancient architecture, and to difinter them from the ruins in which they had been enveloped by time and barbarity. For this purpofe he examined and meafured the ruins of Rome with extreme diligence; he difcovered the orders, and having recognized the rules of the art, was the firft who made a proper application of them in his works. He allied theory to practice, and the profound ftudy of ancient monuments led him to the true principles of fimple and folid conftruction.

The vaft cathedral of St. Maria dei Fiore, at Florence, begun by Arnolfo Lafii in 1298, remained unfinifhed; the original architect had died only two years after the beginning of the building; and to erect a cupola which he had intended as a termination of the edifice, was an undertaking beyond the power of the builders of that age. It was ever regarded as chimerical, and in a convocation architects from various countries affembled in 1420; the moft extravagant plans were propofed without coming to any determination. At length Brunellefchi was entrufted with the enterprize, and he executed it with that facility which, in caufing the difficulties to difappear, is too apt to conceal the merit of an original defign, which none could difcover, but all can imitate.

The dome of St. Maria dei Fiore, which is only inferior in fize to that of St. Peter's, is of an octangular fhape, with a great elevation; it is double, being formed by two vaults which leave an interval between them. It was erected without centering, and it is the only dome which is fupported by the fpringing wall alone, without any kind of counterforts.

This edifice, and many others which Brunellefchi erected, did as much honour to the architect as to the art, and awakened in Italy a general tafte for the true principles of architecture; which was further confirmed by the ftudy of Vitruvius, whofe writings began to excite the attention of the learned.

Alberti, born in 1398, fucceeded to the talents and enterprizes of Brunellefchi, but his great reputation is principally founded upon his treatife "De Re ædificatoria," a profound and valuable work, which has acquired him the title of the modern Vitruvius.

While the principles of conftruction were advancing towards perfection, Bramante, following the example of Brunellefchi in the fedulous ftudy of the remains of antiquity, reftored to architecture the tafte and beauty which had been fo long abfent from her works. Julius II. having formed the project of rebuilding the bafilica of St. Peter on a plan of unequalled magnificence, entrufted the execution to Bramante in 1513. This artift conceived the impofing idea of raifing in the air a cupola as large as that of the Pantheon, or, as he expreffed it, of raifing the Pantheon upon the Temple of Peace; and, in fact, we may trace a great refemblance to thefe two antique edifices in his plan. It is to be lamented that this artift did not poffefs the practice as well as the theory of his art, and the works which he began with fuch carelefs rapidity at St. Peter's have been almoft obliterated by his fucceffors. This vaft undertaking was carried on by Raphael, San Gallo, and Michael Angelo, to whom the final defign of the edifice is principally due.

Under the great names of Vignola, Serlio, Palladio, and Scamozzi, architecture continued to flourifh in the 16th century. Thefe diftinguifhed artifts made the ancient edifices of Rome their fchool, and all ferved their art by their writings as well as by their buildings.

The lift of good Italian architects clofes with Bernini, the moft eminent artift of the 17th century. His contemporary, Boromini, was the corruptor of architectural tafte: of an ungoverned fancy, and tormented with envy of the talents and fuccefs of Bernini, he abandoned every principle of propriety in the wild purfuit of novelty, and buried the forms of art under the moft abfurd and incredible caprices.

Pierre Lefcot is the firft French architect who abandoned the Gothic for the revived antique ftyle. He flourifhed in the beginning of the 16th century. Philibert de Lorme, of the fame age, contributed to the reftoration of the principles of architecture. This architect had ftudied the Roman antiquities, and was a great writer as well as builder.

Francois Manfart, born in 1598, is perhaps the greateft architectural genius that France has produced, but he is reproached with a want of ftability in his ideas, which caufed him to make frequent alterations during the execution of his works, and prevented him from being employed in fome of the greateft undertakings of his age. The Chateau de Maifons, near St. Germain, is one of the chef-d'œuvres of Francois Manfart.

Jules-Hardouin Manfart, a nephew of the preceding, was the chief architect of Louis XIV. and executed the principal works of that magnificent reign: the palace of Verfailles, St. Cyr, and, above all, the place and church of the Invalids.

The façade of the Louvre, one of the moft beautiful examples of modern architecture, was the work of Claude Perrault, who alfo diftinguifhed himfelf by feveral other buildings, and a tranflation of Vitruvius.

Blondel, born in 1617, is celebrated for his knowledge of the fciences and the theory of architecture. His moft celebrated building is the Porte St. Denis. The diftinguifhed name of Soufflot, the architect of the church of St. Genevieve, the prefent Pantheon of Paris, brings down the lift of French architects to our own times.

Gothic architecture had declined in England during the reign of Henry VIII.; and Inigo Jones, the reftorer of ancient architecture, may be regarded as the greateft as well as the earlieft Englifh architect. He was born in 1572, and died 1651. His works are too familiarly known to require defcription in this place, but Greenwich, Whitehall, and Covent-

Covent-Garden, will for ever secure him a name among the most eminent of his profession. It might have been sufficient to the fame of sir Christopher Wren to have erected the second religious edifice of Europe, but innumerable other monuments attest his talent and scientific skill. These two distinguished names form our list of architectural worthies; of the rest who, with various success, have pursued the art, none can be said to have attained any historical eminence.

Civil *Corporation*. See Corporation.

Civil *Day*. See Day.

Civil *Death*, any thing that retrenches or cuts off a man from civil society: as a condemnation to the gallies, perpetual banishment, condemnation to death, outlawry, and excommunication; all which make a man cease to be looked on as a citizen.

The term is likewise applied to those who are no longer capable of acting in temporal concerns; as those who renounce the world, who retire and make vows in a monastery, &c.

Civil *Fruits*. See Fruits.

Civil *History*. See History.

Civil *Injuries*, or *Private Wrongs*, in *Law*, denote those which are an infringement or privation of the private or civil rights belonging to individuals, considered as individuals; in contradistinction to *public wrongs*, which are a breach and violation of public rights and duties, which affect the whole community, considered as a community, and are distinguished by the harsher appellation of *crimes* and *misdemesnors*, which see.

Civil *Law*, *Lex Civilis*, is defined in the Institutes, to be the laws peculiar to each city, or each people; now more properly distinguished by the name of "Municipal Law." But in the modern use, it properly implies the Roman law, contained in the *Institutes*, the *Digest*, the *Code*, and the *Novels*; (which see respectively); otherwise called *lex scripta*, or the *written law*. The Roman law, at its commencement, was very inconsiderable. Under the kings, the people were governed by certain laws prepared by the senate, passed by the kings, and confirmed in an assembly of the people. Romulus, Numa, and Servius Tullus, are celebrated as the most ancient legislators; and each of them claims his peculiar part in the three-fold division of jurisprudence. The laws of marriage, the education of children, and the authority of parents, which may seem to draw their origin from *nature* itself, are ascribed to the untutored wisdom of Romulus. The law of *nations*, and of religious worship, which Numa introduced, was derived from his nocturnal converse with the nymph Egeria. The *civil* law is attributed to the experience of Servius; he balanced the rights and fortunes of the seven classes of citizens; and guarded, by fifty new regulations, the observance of contracts, and the punishment of crimes. The state, which he had inclined towards a democracy, was changed by the last Tarquin into lawless despotism; and when the kingly office was abolished, the patricians engrossed the benefits of freedom.

Papirius, who flourished somewhat before or after the "Regifugium," was the first who made a collection of the regal laws; which took its name from its author, and was called *jus Papirianum*.

The republic, after abolishing the regal government, still retained the royal laws. For, though they were become odious or obsolete, the mysterious deposit was silently preserved by the priests and nobles; and, at the end of 60 years, the citizens of Rome still complained that they were ruled by the arbitrary sentence of the magistrates. Nevertheless, the positive institutions of the kings had blended themselves with the public and private manners of the city. To these they added the laws of the Twelve Tables, drawn by the decemviri, from the laws of twelve of the principal cities of Greece; and the more equitable among the laws hitherto practised at Rome. See Decemvirs and Twelve Tables.

During the time of the republic, and even under the emperors, there were jurisconsulti; who, making public profession of the study of the law, were consulted on the different senses of the laws, and gave answers to the questions proposed to them hereon; which were called *responsa prudentum*, and by Justinian, the *jurisprudentia media*.

The law of the Twelve Tables was at length found so severe, and conceived in such obscure terms, that it was judged proper to moderate, restrain, and ascertain it, by other laws, proposed to the senate by the consuls, and passed at general assemblies of the people; according to the practice that had obtained under the kings themselves: and these were called by way of emphasis *leges*, or the *laws*. Afterwards, the common people differed with the nobility, and during their secession enacted laws of their own, which were called *plebiscita*; and, upon their subsequent reconciliation, these were admitted and universally enforced. The senate was likewise intrusted with a legislative authority; and new laws were made by them, and called *senatus consulta*, and incorporated with the Roman civil law. The prætors, likewise, in the absence of the consuls, had a power of supplying and correcting the civil law of the Twelve Tables, and of proposing edicts, which, when approved by the people, were incorporated into the civil law, under the title of *jus prætorium*. And the ædiles curules did also in some cases enact and establish laws. These several parts, which have been enumerated, composed the Roman civil law during the republic.

In the time of Julius Cæsar, Offilius, a lawyer, began a collection of the edicts of the prætors; but this was not finished till the time of Adrian, by another lawyer; who also digested the edicts of the ædiles curules, which were made perpetual by the Cornelian law. Accordingly, the design which had been conceived by the genius of Cæsar was accomplished by Adrian; and the prætorship of Salvius Julian, an eminent lawyer, was immortalized by the composition of the "perpetual edict." This well-digested code was ratified by the emperor and the senate; the long divorce of law and equity was at length reconciled; and instead of the Twelve Tables, the perpetual edict was fixed as the invariable standard of civil jurisprudence. See Edict.

In the year of Rome 723, B. C. 31, the republic expired; and the whole power of the people was transferred to Augustus, who was contented to publish his new laws in the assembly of the people; to keep up some image of the republic by this formality. Tiberius abolished these occasional assemblies, on pretence of their being too numerous; and in lieu thereof offered his laws to the senate, who never failed to confirm them; insomuch that the laws of Tiberius and his successors, who kept the same measures with the senate, were esteemed *senatus consulta*. They were also called *imperial constitutions*, and sometimes *placita principum*. The *responsa prudentum*, obtained from those to whom the emperors gave commission, and to which the judges were obliged to conform, constituted a part of the *jus scriptum*, or written law. The *imperial constitutions* were digested into four codes, after they were become very numerous under succeeding emperors; their bulk being so great, or, as Livy expresses it, (l. iii. c. 34.) "tam immensus aliarum super alias acervatarum legum cumulus," that they were computed to be many camels' load by an author who preceded Justinian.

This

This was in part remedied by the collections of three private lawyers, Gregorius, Hermogenes, and Papirius; and then by the emperor Theodofius the Younger, by whofe orders a code was compiled, A. D. 438, being a methodical collection of all the imperial conftitutions then in force; which Theodofian code was the only book of civil law received as authentic in the weftern part of Europe till many centuries after; for Juftinian commanded only in the eaftern remains of the empire.

Mr. Gibbon (Hift. Decl. and Fall of the Roman Empire, vol. viii.) divides the interval of almoft 1000 years that elapfed from the Twelve Tables to the reign of Juftinian, into three periods, almoft equal in duration, and diftinguifhed from each other by the mode of inftruction, and the character of the Civilians.

During the firft period, A. U. C. 303—648, pride and ignorance contributed to confine within narrow limits the fcience of the Roman law. On the public days of market or affembly, the mafters of the art were feen walking in the forum, ready to impart needful advice to the meaneft of their fellow-citizens, from whofe votes, on a future occafion, they might folicit a grateful return. As their years and honours increafed, they feated themfelves at home on a chair or throne, to expect with patient gravity the vifits of their clients, who, at the dawn of day, from the town and country, began to thunder at their door. The duties of focial life, and the incidents of judicial proceeding, were the ordinary fubject of thefe confultations, and the verbal, or written opinion of the "jurifconfulti," was framed according to the rules of prudence and law. The youths of their own order and family were permitted to liften; their children enjoyed the benefit of more private leffons; and the Mucian race was long renowned for the hereditary knowledge of the civil law.

The fecond period, A.U.C. 648—988, the learned and fplendid age of jurifprudence, may be extended from the birth of Cicero to the reign of Severus Alexander. A fyftem was formed, fchools were inftituted, books were compofed, and both the living and the dead became fubfervient to the inftruction of the ftudent. The "tripartite" of Ælius Pætus, furnamed Catus, or the Cunning, was preferved as the oldeft work of jurifprudence. Cato the cenfor derived fome additional fame from his legal ftudies, and thofe of his fon; the kindred appellation of Mucius Scævola was illuftrated by three fages of the law; but the perfection of the fcience was afcribed to Servius Sulpicius, their difciple, and the friend of Tully; and the long fucceffion, which fhone with equal luftre under the republic and under the Cæfars, is finally clofed by the refpectable characters of Papinian, of Paul, and of Ulpian. Their names, and the various titles of their productions, have been minutely preferved, and the example of Labeo may fuggeft fome idea of their diligence and fecundity. That eminent lawyer of the Auguftan age, divided the year between the city and country, between bufinefs and compofition; and 400 books are enumerated as the fruit of his retirement. Of the collections of his rival Capito, the 259th book is exprefsly quoted; and few teachers could deliver their opinions in lefs than 100 volumes.

In the third period, A.U.C. 988—1230, between the reigns of Alexander and Juftinian, the oracles of jurifprudence were almoft mute. The meafure of curiofity had been filled; the throne was occupied by tyrants and barbarians; the active fpirits were diverted by religious difputes, and the profeffors of Rome, Conftantinople, and Berytus, were humbly content to repeat the leffons of their more enlightened predeceffors. From the flow advances and rapid decay of thefe legal ftudies, it may be inferred, that they require a ftate of peace and refinement. From the multitude of voluminous civilians, who fill the intermediate fpace, it is evident, that fuch ftudies may be purfued, and fuch works may be performed, with a common fhare of judgment, experience, and induftry. The genius of Cicero and Virgil was more fenfibly felt, as each revolving age had been found incapable of producing a fimilar or a fecond; but the moft eminent teachers of the law were affured of leaving difciples equal or fuperior to themfelves in merit and reputation.

In the 7th century of the city, the jurifprudence, which had been grofsly adapted to the wants of the firft Romans, was polifhed and improved by the alliance of Grecian philofophy. The Scævolas had been taught by ufe and experience; but Servius Sulpicius was the firft civilian who eftablifhed his art on a certain and general theory. The logic of Ariftotle and the Stoics introduced the light of order and eloquence.

After the example of Plato, Cicero, though he declined the reputation of a profeffed lawyer, compofed a republic; and for its ufe, a treatife of laws; in which he labours to deduce from a celeftial origin the wifdom and juftice of the Roman conftitution. Plato, Ariftotle, and Zeno, he reprefents as the only teachers who arm and inftruct a citizen for the duties of focial life. Of thefe, the armour of the Stoics was found to be of the firmeft temper; and it was chiefly worn, both for ufe and ornament, in the fchools of jurifprudence. Auguftus and Tiberius were the firft to adopt, as an ufeful engine, the fcience of the civilians; and their fervile labours accommodated the old fyftem to the fpirit and views of defpotifm. Under the fair pretence of fecuring the dignity of the art, the privilege of fubfcribing legal and valid opinions was confined to the fages of fenatorian or equeftrian rank, who had been previoufly approved by the judgment of the prince; and this monopoly prevailed till Adrian reftored the freedom of the profeffion to every citizen confcious of his abilities and knowledge. The difcretion of the prætor was now governed by the leffons of his teachers; the judges were enjoined to obey the comment as well as the text of the law; and the ufe of codicils was a memorable innovation, which Auguftus ratified by the advice of the civilians. Two fages of the law, Ateius Capito and Antiftius Labeo, adorned the peace of the Auguftan age; and their refpective fchools maintained their inveterate conflict from the age of Auguftus to that of Adrian. (See Capito and Cassiani.) The controverfies of the different fects were in a great meafure determined by the perpetual edict. The lawyers of the age of the Antonines, like the cotemporary philofophers, difclaimed the authority of a mafter, and adopted from every fyftem the moft probable doctrines. An indulgent edict of the younger Theodofius excufed the judge from the labour of comparing and weighing the arguments of different competitors. Five civilians, Caius, Papinian, Paul, Ulpian, and Modeftinus, were eftablifhed as the oracles of jurifprudence; a majority was decifive: but if their opinions were equally divided, a cafting vote was afcribed to the fuperior wifdom of Papinian.

When Juftinian afcended the throne, A.D. 527, the reformation of the Roman jurifprudence was an arduous but indifpenfable tafk. In the fpace of ten centuries, the infinite variety of laws and legal opinions had filled many thoufand volumes, which no fortune could purchafe and no capacity could digeft. Books could not eafily be found; the fubjects of the Greek provinces were ignorant of the language that difpofed of their lives and properties; and the barbarous dialect of the Latins was imperfectly ftudied in the academies of Berytus and Conftantinople. In thefe circumstances, Justinian, finding the authority of the Roman law almost abolished in the West, by the declension of the empire, resolved to make a general collection of the whole Roman jurisprudence, and committed the care thereof to his chancellor Trebonian or Tribonian.

Tribonian was eminently qualified for the office. To the literature of Greece he added the use of the Latin tongue; the Roman civilians were deposited not only in his library but in his mind; and he most assiduously cultivated those arts which opened the road of wealth and preferment. From the bar of the prætorian prefects, he raised himself to the honours of quæstor, of consul, and of master of the offices; the council of Justinian listened to his eloquence and wisdom, and envy was mitigated by the gentleness and affability of his manners. This minister, aided by nine learned associates, began, in the first year of the reign of Justinian, and under his direction, to revise the ordinances of his predecessors, as they were contained, since the time of Adrian, in the Gregorian, Hermogenian, and Theodosian codes; to purge the errors and contradictions, to retrench whatever was obsolete or superfluous, and to select the wise and salutary laws best adapted to the practice of the tribunals and to the use of his subjects. The work was accomplished in 14 months, from A.D. 528, Feb. 13, to A.D. 529, April 7; and the twelve books, or tables, which the new decemvirs produced, might be designed to imitate the labours of their Roman predecessors. The new "Code" of Justinian was honoured with his name, and confirmed by his royal signature; authentic transcripts were multiplied by the pens of notaries and scribes; they were transmitted to the magistrates of the European, the Asiatic, and afterwards the African provinces; and the law of the empire was proclaimed in solemn festivals at the doors of churches. It still remained to extract the spirit of jurisprudence from the decisions and conjectures, the questions and disputes of the Roman civilians. Seventeen lawyers, with Tribonian at their head, were appointed by the emperor to exercise an absolute jurisdiction over the works of their predecessors; and the "Digest," or "Pandects," were rapidly composed in three years, from A.D. 530, Dec. 15, to A.D. 533, Dec. 16. From the library of Tribonian, they chose 40, the most eminent civilians of former times; 2000 treatises were comprised in an abridgment of 50 books; and it has been carefully recorded, that 3,000,000 of lines, or sentences, were reduced, in this abstract, to the moderate number of 150,000. The edition of this great work was delayed a month after that of the "Institutes;" and it seemed reasonable that the elements should precede the digest of the Roman law. The "Institutes," completed A.D. 533, Nov. 21, which comprise an ample system reduced to a short and elementary treatise, are comprehended in four books. (See INSTITUTES.)

The "Code," the "Pandects," and the "Institutes," were declared to be the legitimate system of civil jurisprudence; they alone were admitted in the tribunals, and they alone were taught in the academies of Rome, Constantinople, and Berytus. Justinian addressed to the senate and provinces his "eternal oracles;" and his pride, under the mask of piety, ascribed the consummation of this great design to the support and inspiration of the deity.

In order to maintain the text of the "Pandects," the "Institutes," and the "Code," the use of ciphers and abbreviations was rigorously proscribed; and as Justinian recollected, that the perpetual edict had been buried under the weight of commentators, he denounced the punishment of forgery against the rash civilians who should presume to interpret or pervert the will of their sovereign. Six years, however, had not elapsed from the publication of the "Code," before the versatile emperor condemned the imperfect attempt, by a new and more accurate edition of the same work (A. D. 534, Nov. 16.); which he enriched with 200 of his own laws, and 50 decisions of the darkest and most intricate points of jurisprudence. Every year, or according to Procopius, each day, of his long reign, was marked by some legal innovation. Many of his acts were rescinded by himself; many were rejected by his successors; many have been obliterated by time; but the number of 16 "edicts," and 168 "novels," (A. D. 534—565.) has been admitted into the authentic body of the civil jurisprudence. (See AUTHENTICS and NOVEL.)

All these together, viz. the "Code," the "Digest," the "Institutes," and the "Novels," form the *Corpus juris civilis*, or body of the civil law, as reduced by order of Justinian.

For the space of about 300 years, this system of law obtained without any innovation. But the new constitutions, made by the emperors from time to time, at length occasioning some alterations; the emperor Basil, and Leo his son, composed a new body of the Roman law, chiefly from the Justinian, in the Greek language; dividing it into seven volumes, and 60 books; under the title of "Basilica." From which time, Justinian's body had but little credit in the East; the Basilica taking place of it.

In the West, the civil law had a different fortune; for, though some traces of its authority remained in Italy, yet it was little known in Europe, till a copy of Justinian's "Digests" was accidentally found at Amalfi, in Italy, about the year 1130; and this circumstance, together with the policy of the Romish ecclesiastics, contributed to introduce it into several nations, and occasioned that inundation of voluminous comments, with which this system of law, more than any other, is now loaded.

It is true, however, it was never taught publicly till the 12th century; when the study of it was introduced into several universities abroad, particularly that of Bologna; where exercises were performed, lectures read, and degrees conferred in this faculty, as in other branches of science; and from hence it was carried by Irnerius's disciples into other countries, and in a little time was taught in all the universities.

Many nations, on the continent, just then beginning to recover from the convulsions consequent upon the overthrow of the Roman empire, and settling by degrees into peaceable forms of government, adopted the civil law (being the best written system then extant) as the basis of their civil constitution; blending and interweaving it among their own feudal customs, in some places with a more extensive, in others a more confined authority.

It was first brought over into England by Theobald, a Norman abbot, who was elected to the see of Canterbury in 1138; and he appointed a professor, viz. Roger, surnamed Vacarius, prior of Beck in Normandy, who opened a school in the university of Oxford, to teach it to the people of this country. Nevertheless, it gained ground very slowly; king Stephen, A. D. 1149, issued a proclamation, prohibiting the study of it: upon which Vacarius returned into Normandy, and was chosen abbot of Beck. And though the clergy were attached to it, the laity rather wished to preserve the old constitution.

A kind of persecution was raised against the professors and students of the civil law, by the common lawyers and others; but John of Salisbury says, "that, by the blessing of God, the more the study of it was persecuted, the more it flourished."

The bishops and clergy, many of whom were foreigners, applied

applied themfelves wholly to the ftudy of the civil and canon laws, which now came to be infeparably interwoven with each other; whereas the nobility and laity adhered with equal pertinacity to the common law. Thefe two parties manifefted a reciprocal jealoufy of what they were unacquainted with, and neither of them perhaps allowed (fays judge Blackftone) the oppofite fyftem that real merit which is abundantly to be found in each. This appears, on the one hand, from the fpleen with which the monaftic writers fpeak of our municipal laws upon all occafions; and, on the other, from the firm temper which the nobility fhewed at the famous parliament of Merton. Stat. Merton. 20 Hen. III. c. 9. The fame jealoufy appears above a century afterwards, (11 Ric. II.) when the nobility declared, with a kind of prophetic fpirit, "that the realm of England hath never been unto this hour, neither by the confent of our lord the king and the lords of parliament fhall it ever be, ruled or governed by the civil law." The clergy, however, finding it impoffible to root out the municipal law, began to withdraw themfelves by degrees from the temporal courts; and to that end, very early in the reign of king Henry III., epifcopal inftitutions were publifhed, forbidding all ecclefiaftics to appear as advocates *in foro feculari:* and wherever they retired, and wherever their authority extended, they difplayed the fame zeal to introduce the rules of the civil, in exclufion of the municipal law. This appears in a particular manner from the fpiritual courts of all denominations, from the chancellor's courts in both our univerfities, and from the high court of chancery; in all which the proceedings are to this day in a courfe much conformed to the civil law; for which no tolerable reafon can be affigned, unlefs that thefe courts were all under the immediate direction of the popifh ecclefiaftics, among whom it was a point of religion to exclude the municipal law; pope Innocent IV. having forbidden the very reading of it by the clergy, becaufe its decifions were not founded on the imperial conftitutions, but merely on the cuftoms of the laity. And if it be confidered, that our univerfities began about that period to recover their prefent form of fcholaftic difcipline; that they were then, and continued to be till the time of the reformation, entirely under the influence of the popifh clergy; (fir John Mafon the firft proteftant, being alfo the firft lay chancellor of Oxford), this will lead us to perceive the reafon why the ftudy of the Roman laws was in thofe days of bigotry purfued with fuch alacrity in thefe feats of learning; and why the common law was entirely defpifed, and efteemed little better than heretical. The ftruggle between the laws of England and of Rome was continued through the reign of king Henry II.; the former fupported by the ftrength of the temporal nobility, when the popifh clergy endeavoured to fupplant them in favour of the latter. This difpute was kept on foot till the reign of Edward I.; when the laws of England, under the new difcipline introduced by that fkilful commander, obtained a complete and permanent victory.

Before the reformation degrees were as frequent in the canon law as in the civil law. Many were graduates *in utroque jure* or *utriufque juris.* J. U. D. or *juris utriufque doctor*, is ftill common in foreign univerfities. But Henry VIII., in the 27th year of his reign, when he had renounced the authority of the pope, iffued a mandate to the univerfity of Cambridge, to prohibit lectures, and the granting of degrees in canon law in that univerfity. It is probable that, at the fame time, Oxford received a fimilar prohibition, and that degrees in canon law have ever fince been difcontinued in England. See DEGREE.

However, the zeal and influence of the clergy prevailed; and the civil law acquired great reputation from the reign of king Stephen to the reign of king Edward III. both inclufive. Henry II., who fucceeded Stephen, being a much greater politician, was far from difcouraging the ftudy of the civil law; which, in conjunction with that of the canon law, prevailed very much in the univerfities, but ftill more in the cathedral fchools and monafteries.

Many tranfcripts of Juftinian's Inftitutes are to be found in the writings of our ancient authors, particularly of Bracton and Fleta; and judge Blackftone obferves, that the common law would have been loft and over-run by the civil, had it not been for the incident of fixing the court of common pleas in one certain fpot, and the forming the profeffion of the municipal law into an aggregate body.

It is allowed, that the civil law contains all the principles of natural equity; and that nothing can be better calculated to form good fenfe, and found judgment. Hence, though in feveral countries it has no other authority but that of reafon, and juftice, it is every-where referred to for authority.

It is not received at this day in any nation without fome alterations: and fometimes the feudal law is mixed with it, or general and particular cuftoms; and often, ordinances and ftatutes cut off a great part of it.

In Turkey the "Bafilics" are only ufed. In Italy the canon law and cuftoms have excluded a good part of it. In Venice cuftom hath almoft an abfolute government. In the Milanefe, the feudal law and particular cuftoms bear fway. In Naples and Sicily, the conftitutions and laws of the Lombards are faid to prevail. In Germany and Holland, the civil law is efteemed to be the municipal law: but yet many parts of it are there grown obfolete; and others are altered, either by the canon law, or a different ufage.

In Friezeland, it is obferved with more ftrictnefs: but in the northern parts of Germany, the jus Saxonicum, Lubecenfe, or Culmenfe, is preferred before it. In Denmark and Sweden it hath fcarce any authority at all. In France only a part of it is received; and that part is in fome places as a cuftomary law: and in thofe provinces neareft to Italy, it is received as a municipal written law. In criminal caufes, the civil law is more regarded in France; but the manner of trial is regulated by ordinances and edicts.

The civil law, in Spain and Portugal, is connected with the jus regium and cuftom. In Scotland, the ftatutes of the federunt, part of the regiæ majeftatis, and their cuftoms, controul the civil law.

In England, it is ufed in the ecclefiaftical courts; in the high court of admiralty; in the court of chivalry; and in the courts of the two univerfities: yet in all thefe it is reftrained and directed by the common law. See CANON *Law*.

CIVIL *Liberty*. See LIBERTY.

CIVIL *Lift*, the money allotted for the fupport of the king's houfehold, and for defraying certain neceffary charges of government. See KING and REVENUE.

CIVIL *Month*. See MONTH.

CIVIL *Obligation*. See OBLIGATION.

CIVIL *State*, confifts of the nobility and commonalty, exclufive of the clergy, and of the military and maritime orders.

CIVIL *Subjection*, in *Law*, is a fpecies of compulfive obligation, whereby an inferior is conftrained by a fuperior to an action contrary to what his own reafon and inclination would fuggeft; as when a legiflator eftablifhes iniquity by a law, and commands a fubject to do what is inconfiftent with religion or found morality. This excufe cannot be admitted in *foro confcientiæ*, but obedience to the laws in being is a fufficient sufficient extenuation of civil guilt before the municipal tribunal. Blackst. Com. vol. iv. p. 28.

Civil *War.* See War.

Civil *Year*, is the legal year, or civil account of time, which every government appoints to be used within its own dominions. It is thus called in contradistinction to the natural year; which is measured exactly by the revolution of the heavenly bodies. See Year.

CIVILIANS' *College.* See College.

CIVILISATION, a law or judgment, which renders a criminal process civil. Civilisation is performed by turning the information into an inquest, or *vice versa.*

Civilisation, in *Political Economy*, denotes the conversion or transformation of a country or people from a savage or barbarous state into a state formed by a due regard to the principles and obligations, the habits and manners of social life, by the means of mental and moral instruction, salutary laws, and regular government.

CIVITA, or Civeda, in *Geography*, a town of Italy, in the Bressan, seated on the Oglio, 25 miles W. of Brescia.

Civita *Aquana*, a town of Naples, in the province of Abruzzo Ultra; 15 miles E. of Aquila.

Civita *d'Antina*, a town of Naples, in the province of Abruzzo Ultra; 12 miles S. of Celano.

Civita *Borello*, a town of Naples, in the province of Abruzzo Citra; 19 miles N.N.E. of Molese.

Civita *di Cascia*, a town of Italy, in the state of the Church, and province of Umbria; 5 miles S.W. from Norcia.

Civita *Castellana.* See Castellana.

Civita *di Chieti.* See Chieti.

Civita *Lavinia*, a town of Italy in the Campagna di Roma; 4 miles from Veletri.

Civita *Luparella*, a town of Naples, in the province of Abruzzo Citra; 2 miles N. of Civita Borello.

Civita *Mandonia*, a town of Naples, in the province of Calabria Citra; 15 miles N.N.E. of Bisignano.

Civita *à Mare*, a town of Naples, in the province of Capitanata; 13 miles E.S.E. of Termola.

Civita *Nuova*, a town of Italy, in the marquisate of Ancona, on the road from Loretto to Fermo; 7 miles from the former and 9 from the latter. It is seated near the coast of the Adriatic or gulf of Venice, on a small river or creek. N. lat. 43° 16″, E. long. 13° 46′.—Also a town of Istria, seated on the Adriatic sea, N.W. from Ancona, and 20 leagues E. of Venice, within a small creek or bay, on a prominent part of the coast, E. from Savori. N. lat. 45° 36′. E. long. 14° 2′.

Civita *di Penna*, a town of Naples, in the province of Abruzzo Ultra, the see of a bishop, suffragan of Chieti; 10 miles S.E. of Teramo.

Civita *Real*, a town of Naples, in the province of Abruzzo Ultra, 13 miles N.W. of Aquila.

Civita *di St. Angelo*, a town of Naples, in the province of Abruzzo Ultra, seated on a mountain; 3 miles from Poto di Salino.

Civita *Tomassa*, a town of Naples, in the province of Abruzzo Ultra; 6 miles S.W. of Aquila.

Civita *Vecchia*, or Malta, a town seated on a hill in the centre of the island of Malta, strongly fortified. It is the see of a bishop, and contains, besides a large and handsome cathedral, several other churches and convents. From the town may be seen the whole island, and sometimes the coasts of Africa and Sicily.

Civita *Vecchia*, a fortified sea-port town of Italy, in the state of the church and patrimony of St. Peter, situated in a bay of the Tuscan sea. The port was enlarged and rendered commodious by Trajan; it is the best in Italy, and was declared free by Benedict XIV. It is the usual station for the pope's galleys. The air is unhealthy and the water not good; 27 miles N.W. from Rome. N. lat. 42° 5′ 24″. E. long. 11° 46′ 15″. The alum-work, which is situated about an Italian mile N.W. from Tolfa, and six from Civita Vecchia, is reckoned by some Italian historians to have been the first; however it is certainly the oldest of any that is carried on at present. The founder of it was John di Castro, a son of the celebrated lawyer, Paul di Castro, (See Castro), who had an opportunity at Constantinople, where he traded in Italian cloths, and sold dye-stuffs, of making himself acquainted with the method of boiling alum. Returning to his country upon the capture of the city, he found at Tolfa a plant (the *ilex aquifolium* or holly), which indicated alum in the soil, and which he had observed in the aluminous districts of Asia; and upon examining the soil discovered alum. Pope Pius II. availed himself of the discovery, which was made, according to his account, about the year 1460 or 1465, and this salt was afterwards manufactured in great quantities, and sold to the Venetians, the Florentines, and the Genoese. See Alum.

CIVITALI, Matteo, in *Biography*, a sculptor and architect of some eminence, who was born at Lucca, where, amongst many other works, he constructed in 1444 the little temple, which contains the miraculous crucifix, in the church of St. Martino, a statue of St. Sebastian, and another of the Madonna, which was placed at an angle of the church, on the outside; which works Vasari considers as no wise inferior to those of his master, Giacomo della Quercia. But the greatest work of Civitali in sculpture, is in the chapel of St. John the Baptist at Geneva, where he left six admirable and highly finished statues of white marble, representing Adam, Eve, Abraham, Abias, Zacharias, and Elizabeth. Soprani.

CIVITARA, in *Geography*, a town of Naples, in the province of Capitanata; 2 miles N.E. of Dragonera.

CIVITAS Equestrium, Novodunus, in *Ancient Geography*, a place of Gallian Lyonnensis, which had been an episcopal see till the year 412; now Nions.

Civitas *Nova*, a town of Scythia.

CIVITATES Fœderatæ, were cities, which in consequence of the alliance they had contracted with the Roman people, were obliged when required, although they were governed by their own proper magistrates, to furnish a contingent of auxiliary troops.

CIVITELLA, in *Geography*, a town of Naples, in the province of Otranto; 5 miles N.E. of Tarento.—Also, a fortress of Naples, in the province of Abruzzo Ultra; 7 miles N. of Teramo.

CIVRAC, a town of France, in the department of the Gironde; 7 miles E. of Libourne.

CIVRAY, or Sivray, a town of France, and principal place of a district, in the department of the Vienne, seated on the Charente; $8\frac{1}{2}$ leagues S.W. of Poitiers. The place contains 1484, and the canton 9728 inhabitants; the territory includes $207\frac{1}{2}$ kiliometres, and 14 communes.

CIVRY, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the district of Chateaudun; 7 miles E.N.E. of Chateaudun.

CIUS, in *Ancient Geography*, a river of Lower Mœsia, which had its source in the mountains of Thrace, and discharged itself into the Danube. Eustathius says, that a town of the same name was situated near this river.

Cius, a town of Asia Minor in Bithynia, situated on the sea-coast, at a small distance from Nicæa. It had been episcopal.

CIZARA,

CIZARA, a town of Asia, in the Lesser Armenia, placed by Ptolemy near the Euphrates.

CIZE', in *Geography*, a valley of France, of which St. Jean-Pié-de-port is the capital.

CIZYA, in *Ancient Geography*, a town of Thrace, into which Eustathius was sent as an exile.

CKEBOE, in *Geography*, a town of Norway; 6 miles S.S.E. of Drontheim.

CLACKLAND, a small island of Scotland, near the east coast of the island of Arran.

CLACK *wool, to,* is to cut off the sheep's mark, which makes it weigh lighter; as to force wool, signifies to clip off the upper and hairy part thereof; and to bard it, is to cut the head and neck from the rest of the fleece. Stat. 8 H. VI. cap. 22.

CLACKMANNAN, in *Geography*, the principal town of the county of Clackmannanshire, stands on an eminence 190 feet above the level of the Forth, which descends gradually on each side of the town, but on the western, where the ancient tower of Clackmannan is situated, the ground is broken, and discovers vast rocks of the most romantic forms, which give great interest to the admirable view from the venerable structure just mentioned, originally built by king Robert Bruce, and for a long time the residence of the Bruces. The town possesses few attractions; and though the principal street is broad and convenient, yet the mean appearance of many of the houses gives an air of wretchedness to the place, which seems confirmed by the ruinous state of the tolbooth and court-house, where the election for a member of parliament is held, and at intervals the sheriff's court. The inhabitants are indebted to the river Devon for their harbour, which enters the Forth at Clackmannan, and to sir Lawrence Dundas for its improvement in 1772: the mean depth of water is at present 20 feet at the mouth of the harbour, and 10 at the shipping-place. The town pays feu duty to the proprietor of the estate of the same name, on which it stands. The population amounts to 640.

Clackmannan parish is about six miles in length, and nearly five in breadth. Eight hundred acres of this parish are covered with natural woods, which are highly useful and ornamental; the remainder of the land is arable, and very productive, with the exception of a small proportion that is clay, and consequently wet. The gentlemen farmers of the county formed a club, twenty years ago, for the express purpose of introducing agricultural improvements, from which great advantages have been derived; nor are the natives less indebted to the Devon Iron Company, who have furnished employment to numbers at their extensive works, erected on the estate of lord Cathcart, near which is the new and flourishing village of Newtonshaw. There are, besides, two large distilleries at Kilbagie and Kennet-Pans: at the latter place is a commodious harbour. Coal, limestone, and freestone, are very plentiful throughout the parish, which is intersected by the rivers Ford and Devon. Population 2528, in 1791.

CLACKMANNANSHIRE, a county of Scotland. This district, which is about nine miles in length, and not exceeding eight in its greatest breadth, is bounded on the south and south-west by Stirlingshire and the frith of Forth, and on the west, north, and east, by Perthshire. The coast is highly favourable to the fisherman and mariner, as it furnishes many excellent harbours for shipping, and creeks for the reception of boats. The surface rises from the shore, and forms the Ochil mountains, of which Bencleugh, in the parish of Tilly-coultry, is the highest; the plain near the Forth is extremely fertile, producing great crops of corn, and abounding with rich pastures. Although the farmers of this county have made considerable improvements in agriculture, and are enabled to export a great deal of grain, they turn their attention rather to raising flocks and herds than wheat, for which they have strong inducements in the plentiful feed for sheep, furnished by nature on the sides of the Ochil mountains. These eminences contain valuable ores of silver, lead, copper, cobalt, and antimony, besides beautiful specimens of iron ore, agates, pebbles, and a few topazes. In addition to these advantages, the district abounds with coal throughout, freestone, and granite, the conveyance of which has lately been greatly facilitated by the introduction of turnpike roads. There are four parishes, the county town, and a large village named Alloa in Clackmannanshire, which, in conjunction with the county of Kinross, sends one member to parliament. "The valued rent is 26,482*l.* Scots, and the real land rent is about 14,200*l.* sterling." The population, according to the enumeration returned to sir John Sinclair, was 8749. The principal mansions situated within the county are Tullibody, the residence of the family of Abercromby; Clackmannan, that of Mr. Bruce of Kennet; Shawpark and Alloa, the former the seat of lord Cathcart, and the latter of the Erskines of Alloa.

CLACKNACARRY, a village in Invernessshire, in Scotland, about $1\frac{1}{2}$ mile N. of the town of Inverness; it is situate on the S.W. side of loch Beauly, and at the east end of the intended *Inverness and Fort-William*, or Caledonian Canal, the works of which are rapidly proceeding. The spring-tides here rise about 11 to 15 feet, neap tides 7 feet. In 1804, the excavation of the bason and sea-lock at this place were begun; an immense embankment was begun, which, in May 1806, had extended 240 yards into the lock, or two-thirds of its intended length, for inclosing the site of the sea-lock, which is therein to be built for the admission of ships and vessels as large as 32-gun frigates. A rail-way has been formed for bringing earth from the hill on the west side of the road from Inverness to Beauly, and under which it passes, for completing the embankment in the sea above mentioned: another rail-way has been laid, from the Rubble-Stone Quarry in Clacknacarry to this embankment, and also to the second lock on the canal, the masonry of which is now (1807) in a great measure completed. Clacknacarry may be expected hereafter to become a considerable place of trade, when this stupendous and important canal of communication between the east and west seas is completed.

CLADAUS, or CLADEUS, in *Ancient Geography*, a river of Peloponnesus, in that part of the Elide called Triphylia. It discharges itself into the Alpheus; and Pausanias says, that the inhabitants of the Elide paid religious worship to this river.

CLADEUTERIA, in *Antiquity*, a festival celebrated at the time of pruning the vines. It was likewise called *lisbœa*.

CLADIUS, *in Natural History*, a name given by the ancients to the stag or deer, when four years old; in this year, or at the end of it, it was called *cerastes*. The Greeks had names for all the years' growth of this animal up to its perfection: in the first year they called it *nebrus;* in the second *pattalea;* in the third *dicrotus;* and in the fourth *cladius*, or *cerastes* towards the end of that year. This name the creature retained all its life afterwards, it being supposed at its full maturity at that time.

CLADODES, in *Botany*, Bosc. Nouv. Dict. Lour. Flor. Cochin. Class and order, *monœcia polyandria*.

Gen. Ch. *Cal.* four-leaved; leaves oval, concave. *Cor.* none. *Stam.* in the *male*, filaments eight, membranous. *Pist.*

in the *female*, germ superior, trigonous; stigmas three, sessile, oblong. *Peric.* capsule nearly round, three-lobed, three-celled, three-valved. *Seeds* one in each cell.

Sp. C.—A shrub. *Leaves* alternate, lanceolate, smooth, wrinkled. *Flowers* small, in terminal racemes. A native of Cochinchina.

CLADONIA, a genus formed, by Hoffman, out of the lichens of Linnæus. It is figured by him in Pl. 25. of his Plantæ lichenosæ, and belongs to the Scyphiphora of Ventenat. See LICHEN and SCYPHIPHORA.

CLAESSEN, AERT, or ALAERT, in *Biography*, a painter of some eminence, born at Leyden in the year 1498. At a very early period he evinced a strong inclination for painting. In 1516, he became the scholar of Cornelius Engelbrechtsen, and by his continued application shortly acquired proficency in his art. He chiefly employed his talents in painting subjects from the Old and New Testament, or other well known histories; and rejected the allurements of poetical fictions, or fabulous images. Though his compositions were good, his manner of painting was by no means pleasing. At first, his style resembled that of his master, Engelbrechtsen; but this he changed upon seeing the works of John Schoorel: he imitated M. Hemskerck in the richness of architectural decoration.

Claessen was as remarkable for his modesty as for his professional merit; and he could never be persuaded to quit the tranquil obscurity of his situation for the honours which his talents as an artist would have intitled him to. His facility in composing was astonishing; and he made a vast number of drawings for the painters on glass, for which he never received a greater price than seven-pence each. The family Buytenwegh, at Leyden, possessed three pictures of this artist, which were full of expression. The first was Christ on the Cross, between the Two Thieves, with the Maries, and other figures below. The second represents our Saviour bearing the Cross, followed by his disciples and a multitude of people; and the third, Abraham conducting his son Isaac, loaded with wood, to the place of sacrifice. H. Galtzius at Haerlem, had another picture of this artist, which he highly esteemed. The subject was the passage of the Red Sea: the variety of the figures, and the singularity of the dresses and turbans were surprising.

The death of Aert Claessen was occasioned by his falling into a canal, where he was unfortunately drowned, in the year 1564. Descamps.

CLAGENFURT, in *Geography*, a town of Germany, and capital of the duchy of Carinthia, seated on the Glan, built in a square form, and surrounded with a good wall. It has six churches and three convents; a manufacture of cloth, and a society for the promotion of agriculture and useful arts; 50 miles N. of Trieste. N. lat. 46° 45′, E. long. 14° 11′.

CLAGGAN BAY, a bay in the county of Galway, Ireland, south of Claggan point. It is of easy access, has clean, good holding ground, and pretty well sheltered, with depth of water sufficient for the largest ships. M'Kenzie.

CLAGGAN *Point*, a cape of Ireland on the west coast of the county of Galway, long. 10° 4′ west from Greenwich, lat. 53° 34′ N.

CLAIC, Fr. a hurdle, or sort of rectangular wicker-work. Hurdles serve at sieges in lieu of blinds or mantelets, when there is a want of them, to cover a lodgment, a sap, or a passage of the ditch. They cover them with earth in order to guard them against fire-works. They make use of *pitched claics*, or hurdles, with good effect for making causeways in boggy or marshy places, when the water is carried off from them by drains.

CLAIM, in *Law*, a challenge of interest in any thing that is in possession of another; at least out of a man's own. See NON-CLAIM.

There are divers sorts of claims; as claim by charter, by descent, by acquisition, &c.

Claim is otherwise defined to be a challenge of the ownership or property which one hath not in possession, but which is detained from him by wrong. It is either verbal, when a person by words claims or challenges the thing that is not in his possession, or it is by an action brought, &c.; and it relates sometimes to lands, and sometimes to goods and chattels. Where any thing is wrongfully detained, this claim should be made; and the person who makes it may thus avoid descents of lands, disseisins, &c. and preserve his title, which would otherwise be in danger of being lost. Co. Litt. 250. A man who hath present right or title to enter, must make a claim; and in case of reversions, &c. a person may make a claim, when he hath right, but cannot enter on the lands; and when he dares not make an entry on the land, for fear of personal injury, he may approach as near as he can to the land, and claim the same; and this shall be sufficient to vest in him the seisin. 1 Inst. 250. If nothing hinders a man, having right to land, from entering or making his claim; he must do it before he shall be sued to be in possession of it, or can grant it over to another; but where the party who hath right is already in possession, and where an entry or claim cannot be made, it is otherwise. 1 Rep. 157. A claim may be made by the party himself, and sometimes by his servants or deputy; and a guardian in socage, &c. may make a claim, or enter in the name of the infant that hath right, without any commandment. Co. Litt. 245. Claim or entry should be made as soon as may be; and by the common law it is to be within a year and a day after the disseisin, &c.; and if the party who hath unjustly gained the estate, do afterwards occupy the land, in some cases an assise, trespass, or forcible entry may be had against him. Litt. Sect. 426, 430. If a fine is levied of lands, strangers to it are to enter and make a claim within five years, or be barred; infants after their age, feme-coverts after the death of their husbands, &c. have the like claim, by stat. 1. R. III. c. 7.

CLAIM, *Continual*, a claim made from time to time, within every year and day, to land, or other thing, which, on some accounts, cannot be attained without danger.

Thus, if I am disseised of land, into which, though I have a right, I do not enter for fear of being beaten; I am to hold on my right of entry at my best opportunity, by approaching as near as I can, once every year, as long as I live: and thus I leave the right of entry to my heir. This claim, if it be repeated once in the space of every year and day (whence it derives the name of continual claim), has the same effect with, and in all respects amounts to, a legal entry. Litt. §. 419. 423. By stat. 32 Hen. VIII. c. 43. five years must elapse without entry or continual claim, in order that a descent on the disseisor's death should take away the entry of the disseisee, or his heir; but after the five years, the disseisee must make continual claim as before the statute. And by stat. 4 Ann. c. 16. §. 14. no claim (or entry) shall be of effect to avoid a fine, unless an action shall be commenced thereon within a year, and prosecuted with effect.

CLAIM *of liberty*, a suit or petition to the king in the court of Exchequer, to have liberties and franchises confirmed there by the king's attorney-general.

CLAIM, *False*. See FALSE.

CLAIM, *Quit*. See QUIT.

CLAIN,

CLAIN, or CLANE, in *Geography*, a ſmall fair town on the river Liffey, in the county of Kildare, Ireland, which gives name to the barony. At an abbey here, the ruins of which are ſtill ſeen, a ſynod was held in 1162. It is 16 miles W. from Dublin.

CLAIN, a river of France, which paſſes by Poictiers, and runs into the Vienne; 3 miles S. of Chatellerault.

CLAIR, JEAN MARIE LE, in *Biography*, a French violiniſt of great merit and celebrity for compoſition, as well as performance. Though contemporary with Rameau, his melody and ſtyle were ſuperior to thoſe of that eminent theoriſt and opera compoſer. The productions of Le Clair manifeſt original genius, as well as knowledge of harmony, and the finger-board of his inſtrument. His ſolos were printed in England by Walch, and uſed to be frequently and admirably played by Pinto.

Le Clair was born at Lyons, 1697, and died at Paris in 1764. His early inclinations led him to the art of dancing, and he firſt appeared on the ſtage at Rouen as a dancer. By a ſingular chance, the famous Dupré was at that time the leader of the orcheſtra at the Rouen theatre, as firſt violin; but both, diſcontented with their talents, did juſtice to each other, and changed places: Dupré became the firſt dancer that ever exiſted, and Le Clair ſoon opened a new path to harmony.

Batiſte and Guignon at that time enjoyed great reputation; but Le Clair eſtabliſhed his fame upon a more ſolid foundation, by the manner in which he performed double ſtops: a new ſtyle, at firſt introduced by Batiſte, but which Le Clair brought to the higheſt degree of perfection.

Le Clair, ſtill aſpiring at greater perfection in his art, went to Holland, and placed himſelf under the celebrated Locatelli, the greateſt performer on the violin of his time; and returning to Paris, excited admiration in all who heard him.

His ſolos, duets, trios, and concertos, were long in univerſal favour, and ſtill form the beſt ſchool for the violin in France, as the works of Corelli do in Italy. His opera of *Sylla* and *Glaucus* had no extraordinary ſucceſs; there are in it, however, many excellent parts, which have been inſerted in other operas, and are always heard with pleaſure.

The ſimplicity of Le Clair's character inclined him to diſlike the great world, and its turbulence, and determined him to retire to a ſmall houſe of his own in the ſuburbs of Paris: but in going home, after ſupping in town, October 22d, 1764, he was aſſaſſinated, without its ever being diſcovered by whom, or for what.

CLAIR, in *Geography*, a country of America, in the territory N.W. of the Ohio; laid out in April, 1790.

CLAIR, ST. a fort of America in the ſtate of Ohio, ſituated 25 miles N. of fort Hamilton, on a ſmall creek which falls into the Great Miami, and 21 miles S. of fort Jefferſon.

CLAIR, ST. the name of a *lake* lying about midway between lake Huron and lake Erie, about 90 miles in circumference, and comprehending, according to the meaſurement of Mr. Hutchins, 89,500 acres. It receives the waters of the three great lakes, Superior, Michigan, and Huron, and diſcharges them through the river or ſtrait, called Detroit, into lake Erie. This lake is of a circular form, and navigable for large veſſels, except a bar of ſand towards the middle, which prevents loaded veſſels from paſſing. The cargoes of ſuch as are freighted muſt be taken out, carried acroſs the bar in boats, and then re-ſhipped. The fort of Detroit is ſeated on the weſtern bank of the river of the ſame name, about 9 miles below lake St. Clair.

CLAIR, ST. a town of France in the department of the Channel, and chief place of a canton, in the diſtrict of St. Lô; the place contains 644, and the canton 9647 inhabitants; the territory includes $127\frac{1}{2}$ kiliometres and 16 communes.

CLAIRA, a town of France, in the department of the Eaſtern Pyrenees; 5 miles N.E. of Perpignan.

CLAIRAC, a town of France, in the department of the Lot and Garonne, advantageouſly ſituated in a valley on the Drot, and containing about 3000 inhabitants; who cultivate tobacco and corn, and make a great quantity of wine and brandy; one league S.E. of Tonneins, and $4\frac{1}{2}$ N.W. of Agen.

CLAIRAUT, ALEXIS-CLAUDE, in *Biography*, a celebrated mathematician, was born at Paris in 1713, and, under the inſtruction of his father, who was a teacher of mathematics in that city, he made a ſurpriſing proficiency at a very early age in this department of ſcience. When he was 4 years old, he had learned to read and write; at the age of 9 and 10 years he appears to have been well acquainted with algebra, geometry, and conic ſections; and between 12 and 13 he read a memoir to the Academy of Sciences, concerning four geometrical curves of his own invention. At this early period he ſeems to have laid the foundation of his work on curves, having a double curvature, which he finiſhed in 1729, before he had completed his 16th year. At the age of 18, or in 1731, he was nominated adjunct mechanician to the Academy; in 1733 aſſociate, and in 1738 penſioner. Few, if any, of the members of this learned ſociety contributed a greater number and variety of ingenious papers on the ſubjects of aſtronomy, mathematics, optics, &c. to its memoirs, from the year 1727 to 1762, than M. Clairaut. His memoir "De l'Orbite de la Lune dans le Syſteme de Newton," was communicated to the Academy in 1743; and he proſecuted the ſubject in ſeveral ſubſequent memoirs and ſeparate publications. In 1750 the Academy of Peterſburgh propoſed a prize for the year 1752, on the ſubject of the lunar motions, with a view of aſcertaining "whether all the inequalities that had been obſerved in the motion of the moon are conformable to the theory of Newton, and what is the true theory of theſe inequalities, by means of which the place of the moon might be exactly determined at any given moment?" Clairaut obtained this prize, and his paper on the ſubject was printed at Peterſburgh in that year in 4to. He alſo gained another prize for his new lunar tables, publiſhed in 1754, under the title of "Tables de la Lune, calculées ſuivant la Théorie de la Gravitation univerſelle," Paris, 8vo. In 1765 he publiſhed a new edition of the piece which had gained the prize at Peterſburgh in 1752, and alſo new "Tables of the Moon," ſomewhat different in form from thoſe which he had preſented to the public in 1754. In the year 1756 M. D'Alembert publiſhed a new edition of his "Tables," which had appeared in 1754, in his "Recherches ſur differens points importans du Syſtéme du Monde," and which Le Monnier had publiſhed in his "Inſtitutions Aſtronomiques." About this period commenced the diſpute between Clairaut and D'Alembert, concerning their reſpective theories, which engaged the public attention for ſome years; the papers of Clairaut, relating to this controverſy, were communicated to the public in the "Journal des Savans" for 1758, 1759, 1761 and 1762. Beſides the various communications abovementioned, and others inſerted in the Memoirs of the Academy, M. Clairaut publiſhed the following works ſeparately, *viz.* "On Curves of a double Curvature," in 1730, 4to.; "Elements of Geometry," 1741, 8vo.; "Theory of the Figure of the Earth," 1743, 8vo.; "Elements of Algebra," 1746, 8vo.; and "Tables of the Moon," 1754, 8vo. Clairaut died, at the age of 52 years, on the 17th of May 1765.

1765. Montucla, Hist. des Mathem. by De la Lande, vol. iv.

CLAIRE, in *Geography*, a town of France, in the department of the Lower Seine, 10 miles N. of Rouen.

CLAIR-OBSCURE, or CHIARO-SCURO, one of the great component parts of painting or drawing, is the art of distributing the lights and darks in a picture, in such a manner as to give at once proper relief to the figures, the best effect to the whole composition, and the greatest delight to the eye.

Chiaro-scuro, the original word is Italian, and compounded of *chiaro, light*, and *oscuro, dark*.

Although the word chiaro-scuro is generally considered as synonymous with light and shade, yet it is proper to observe, that it is of a more extended sense; as it denotes not only the lights and shades of a picture, but also its lights and darks, of what kind soever. In this latter sense chiaro-scuro is so nearly allied to colouring, that, for some centuries, it was not thought possible to disunite them.

The engravers, from the earliest period of their art till the time of Rubens, never attempted more than to give to each object in their engravings its proper lights and shades, leaving to painting alone the privilege of producing effect of chiaro scuro, by the opposition of objects of dark local colour to light ones. Thus, the effect of chiaro-scuro, so forcible in the picture, was weak and incomplete in the print; the lights upon a piece of black drapery, or any other dark-coloured object, being left the same as those upon a white, or light-coloured object. But engravers at present, by adopting a different principle, are enabled to make the effect of their prints, so far as relates to chiaro-scuro, as rich and powerful as it is in the pictures they copy: this is done by giving, besides the lights and shades, the relative lightness or darkness of the local or proper colour of each object in the picture, thereby producing what is called by artists the tone of the picture.

A thorough conception and knowledge of the chiaro-scuro is of the greatest importance to the painter. It is chiefly by the proper application of that branch of the art that he is enabled to make the various objects in his picture appear to project or recede, according to their relative situations or distances; and thus far the principles of it are necessary to the artist, ere he can hope to render his imitation just or intelligible. But, it being required in the works of fine art, not only that truth should be told, or that beauty should be represented, but likewise that the one and the other should be made appear to every possible advantage; it has, therefore, ever been the study of great painters, not only to give the due appearance of roundness, or projection to the objects in their pictures, by proper lights and shadows; but likewise to unite or contrast the masses of light and dark, in such a manner as to give at once the most forcible impression to the imagination, and the most pleasing effect to the eye.

Chiaro-scuro may, therefore, be said to be of two kinds; that which is necessary, and that which is expedient or ornamental.

The first kind has been, in a greater or less degree, understood and practised from the revival of painting in the thirteenth century; and, in short, it was utterly impossible that any artist should have attempted to imitate on a plain surface the appearances of round bodies, without discovering the necessity of lights and shades. However, even this, which may be called natural chiaro-scuro, was but very imperfectly understood till the time of Masaccio, near the middle of the 15th century; the painters, prior to this period, having had very little idea of what are called projecting shadows; such as are thrown upon one object, by another intervening between it and the rays of light. Indeed, in the pictures of most of the old painters who preceded Lionardo da Vinci, the ground on which the figures stand, is made so light on that side where this projecting shadow should be thrown, that they frequently seem to have only air to support them.

Lionardo da Vinci, towards the end of the 15th, and the beginning of the 16th century, was the first who, in his admirable writings, as well as in his pictures, treated the subject of chiaro-scuro scientifically; but although the few remaining works of his pencil have prodigious force, rotundity, and softness; yet the system which he recommends and generally adopted, of relieving the dark side of his figures by a light back-ground, and the light parts by a dark one, prevented that expansion and breadth of effect which the great Coreggio soon after discovered could only be attained by a contrary mode of conduct, that of relieving one shadow by another still darker, and of uniting several light objects into one great mass.

The conduct of Coreggio, with respect to his lights and shadows, is worthy the most attentive consideration; and there never, perhaps, was a painter who, independent of the advantage, which he well knew how to take, of the occasional opposition of dark to light-coloured objects, produced so simple, so grand an effect of chiaro-scuro. His figures, as well as the other objects in his pictures, are at all times so disposed, as naturally to receive the light exactly in those parts where it is most wanted, and best suits the effect of the whole; and yet this is done so skilfully, and at the same time with such an appearance of ease, that neither propriety nor grace of action seems in anywise to be sacrificed in the astonishing combination.

The principal painters of the Venetian school, Giorgionè, Titian, Bassan, Tintoret, and Paul Veronese, were great masters of effect; but with them this effect is more frequently the result of accordance or opposition of the local colours of the different objects composing their pictures, than of any very studied or remarkably skilful disposition of the masses of lights and shadows.

Michelangiolo da Caravaggio, who flourished at the end of the sixteenth century, and Guercino, who came soon after, produced the most powerful effects of chiaro-scuro, by means widely different from those adopted by any of their predecessors: but though they rendered their pictures most striking, by reason of the very strong oppositions of light and shadow, which they made almost constantly to pervade them, beauty of form and expression was too frequently sacrificed to force; and we are taught this truth, that chiaro-scuro, like many other parts of painting, cannot be carried beyond certain limits, but at the expence, more or less, of the other essentials of the art.

Gerard Hunthorst, called by the Italians Gherardo della Notté, and Adam Elshemer, produced astonishing effects of chiaro-scuro in their candle and moon-light pieces, which are deservedly in the highest estimation with the lovers of painting; whilst Rubens, with his all-commanding genius, grasped the various magic treasures of the pencil, and by uniting the wide expansive effect of Coreggio, the richly contrasted tints of the Venetians and the force of Caravaggio, has only left us to regret, that his magnificent inventions were not drawn with the purity of Raffaele, or the correctness and grandeur of Buonaroti.

If Rubens astonishes by his unbounded display of light, the parsimonious use made of it by Rembrant, is not less captivating or surprising. Rembrant considered the lights in his pictures as so many gems, acquiring increased lustre from

from their rarity; and indeed the ſtriking effect he has produced by the extraordinary means he adopted, happily ſhews, how vain the attempt to limit or reſtrain by rules the workings of genius in the human mind.

An attentive ſtudy of the works of theſe great maſters, either in their pictures or prints, together with a conſtant reference to nature, is the ſureſt method of attaining a knowledge of the chiaro-ſcuro; but although, in this caſe, precept can in no wiſe ſuperſede example, a few remarks may be of uſe in directing the ſtudent.

Effects of chiaro-ſcuro are produced by combinations of lights, middle tints, and ſhadows; to which may be added, as was before obſerved, the oppoſitions of dark coloured objects to light ones.

Light, as applicable to painting, may be conſidered of four kinds: firſt, that proceeding without interruption, immediately from the ſun to the object; this cauſes very forcible and cutting ſhadows, and ſtrong reflected lights, from one object to another; but though the chiaro-ſcuro thus produced is moſt brilliant and powerful, the means will ſeldom be reſorted to by thoſe artiſts who are unwilling to ſacrifice beauty of form, or delicacy and truth of expreſſion, to glitter and ſplendour of effect, unleſs indeed in landſcape, to which the glow of ſun-ſhine alone gives life and animation.

The ſecond kind of light is that produced when the rays of the ſun are interrupted by clouds or miſts: this is what Lionardo da Vinci calls the univerſal light, and which he particularly recommends, as it gives an effect at once broad, rich, ſimple, and tranquil, and in no degree deſtroying the beauty either of forms or expreſſion. In this caſe, the lights and ſhades are ſoftly and imperceptibly blended into each other, and the reflected lights are proportionally leſs diſcernible.

The third kind of light is that of the moon, of a cold hue, and infinitely leſs powerful than that of the ſun. The ſtill effects of moon-light have never been more truly deſcribed, than by the exquiſite and feeling pencil of Vanderneer, many of whoſe works in this way are beyond all price.

The fourth kind of light is ſuch as proceeds from torches, candles, or any other artificial flame. This kind of light tinges the object it illumines with its own yellow hue; its influence is but ſmall, except upon objects near it, and the ſhadows are proportionally dark and extended.

Painters have, by combining the various properties of theſe different ſorts of light, produced a fifth kind, which may be termed ideal, or pictureſque light; thus Rubens, amongſt others, has not unfrequently united in one picture the brilliant illumination cauſed by the direct rays of the ſun, and thoſe forcible reflections which in nature are only the conſequence of ſuch powerful light, with that ſoftneſs and repoſe which the more quiet, or what Da Vinci terms univerſal light, is alone calculated to occaſion. Caravaggio and Spagnoletto joined the deep ſhadows of night to meridian brightneſs; and many of their extravagant followers who painted at Venice about 1640, acquired by their diſmal and almoſt midnight effects, the appellation of the "*Setta de tenebroſi*," the gloomy ſect of painters.

However, when this ideal chiaro-ſcuro is uſed with diſcretion, and employed in ſuch a manner as to co-operate with, or increaſe the expreſſion of the picture, by its conformity to the character of the ſubject repreſented; more beautiful and ſtriking effects are the reſult, than could have been occaſioned by the moſt exact imitation of any real appearance in nature. For it is ever to be remembered, that not the mere imitation, but, as it were, the rivalſhip of nature, ſhould be the exalted aim of the artiſt who is ambitious of ſhining in the higher departments of painting, ſculpture, or indeed any of the fine arts.

The middle tint is occaſioned by the rays of light ſtriking in a ſide direction, or obliquely on the object; it is neither light nor dark, but that beautiful medium by which the ſkilful artiſt is enabled to blend, by imperceptible gradations, the extremes of both. The management of the middle tints is of the greateſt importance, but can only be learned by frequent examinations of the works of the greateſt painters, and an aſſiduous ſtudy of nature.

With reſpect to ſhadows, it has been before obſerved, that in nature they ever appear powerful and abrupt, in proportion as the light is forcible; and that in theſe caſes the reflected lights, caſt by reverberation, from the enlightened part of one object upon the ſhaded ſide of another object oppoſite to it, are ſtrong. Theſe reflected lights, when well managed, produce moſt beautiful effects upon fleſh and other ſemi-tranſparent bodies, and are frequently of great uſe in harmonizing and uniting thoſe maſſes of light which would otherwiſe have been broken into ſmall parts, or diſagreeable forms; beſides which, a greater appearance of projection can ſometimes be given by a reflected light, than could have been accompliſhed by the introduction of the ſtrongeſt ſhadow.

The doctrine of reflections, and indeed every thing that relates to chiaro-ſcuro, is clearly exemplified in the works of Rubens, Jordaens, and Rembrant; but it is proper to obſerve, that the former, both with reſpect to his effects of chiaro-ſcuro and colouring, ſometimes "o'erſteps the modeſty of nature."

The great merit of Rubens is moſt conſpicuous in his large works, where the diſtance intervening between the eye of the ſpectator and the picture effectually blends and harmonizes all the tints; in his eaſel pictures, the artifice by which his effect is produced is generally too apparent, his tranſitions are too abrupt, and his reflections more powerful than nature can juſtify.

Shadows may perhaps be properly divided into two kinds: firſt, the ſimple ſhadow; ſuch as is naturally occaſioned upon that ſide of an object which is not turned towards the luminary; and, ſecondly, the projecting ſhadow, which takes place upon that ſide of an object which is turned towards the luminary, in conſequence of the intervention of ſome other object between it and the luminary. The projecting ſhadow is always darker in its origin, than the ſhaded ſide of the intervening body which occaſioned it, and for this reaſon: that ſide of an object upon which the projecting ſhadow is thrown, being turned towards the dark ſide of the object which occaſioned it, can receive no reflected light; whereas the ſhaded ſide of the intervening body which occaſioned the projecting ſhadow can receive reflected light, being turned towards the illuminated parts of other objects in the picture.

The knowledge of lights and ſhades is nearly connected with the ſcience of perſpective, and, in particular, when buildings or other regularly formed objects are to be repreſented; great benefit may be derived from the rules of Dr. Brooke Taylor. See Perspective.

It may here be neceſſary to ſay a few words reſpecting what are called by painters accidental or catching lights, and accidental ſhadows. The accidental light is in fact generally no other than a ſmall portion of the common light, ſtriking as it were partially upon ſome ſmall object, or part of a large object, ſurrounded by large maſſes of ſhadow. Fine effects of this kind are to be obſerved in the landſcapes of Rembrant, where the ſcene, generally in ſhadow, or middle tint, is partially illumined by the rays of the ſun, ſtriking through the apertures of a cloud. Parmagiano, in a picture of the marriage of St. Catharine, has produced a very beautiful and striking effect, by the introduction of a light which may be justly styled accidental. The principal group, which is in a room, is illumined from the left; behind the Madonna is a door opening into another room, where Old Joseph receives the light by means of a window opening to the right; thus two contrary lights are introduced in the same picture, and yet without departing from the laws of nature. This elegant work of genius was commented on by Lomazzo, in his "Treatise on Painting," and is now in the possession of William Morland, esq.

Another species of accidental light, is occasioned by the introduction of a second light in a picture, different in kind from the principal light. Thus, in the kitchen scenes of Bassan, Teniers, or Ostade, when a fire is introduced, in some part of the picture, the composition being otherwise illumined by the light of day; this fire becomes an accidental light; and the case is similar, when, in one corner of a moonlight, the fishermen are represented, by their warm fire, mending their nets against the morning's dawn.

In the Fresco of Raffaele, in the Vatican, of St. Peter delivered out of prison, there are three distinct kinds of light; the first and principal light is occasioned by irradiation from the angel, the second proceeds from a torch, and the third from the moon. Such accidental lights, when skilfully and judiciously introduced, never fail to produce a beautiful and striking effect; but they should never be admitted, except in those subjects which seem naturally to require, or to allow of them.

With regard to what are called accidental shadows, it may be sufficient to observe, that if any difference exists between them, and projecting shadows, it is this only; the accidental shadow is generally caused by the intervention of a body, at some distance from the object overshadowed, and consequently, the accidental shadow is less powerful, and less edgy, than the projecting shadow. In landscape, great scope is allowed in the introduction of accidental shadow, it being easily accounted for, by the supposition of clouds, mountains, or other objects; but, in historical painting, an accidental shadow should never be resorted to, unless the cause of that shadow can be made apparent in the picture; it is true that Sir Joshua Reynolds, in one of his lectures, seems inclined to justify the conduct of Paul Veronese, when in one instance he departed from this rule; but, perhaps, a notion inadvertently stated, even by so great an artist, should carry with it little weight, when opposed to the opinions and authorities of the most celebrated painters of every age; the circumstance is here mentioned, because this supposed licence has been so eagerly caught at, and so frequently, we might say unnecessarily, resorted to, by painters of the present day.

With respect to the knowledge of chiaro-scuro, possessed by the ancients, we are but imperfectly informed; however, if we can form any judgment from the paintings discovered at Herculaneum, and in the baths of Titus at Rome (which, although, perhaps, not executed by the most eminent artists, may nevertheless be reasonably supposed to approach them in point of merit, as much with respect to chiaro-scuro, as to the other parts of the art), this part of painting, as well as perspective, was but little understood by them. Mr. Webbe, however, in his Treatise on Painting, strenuously supports the antients on this question, but perhaps not upon sufficient grounds; to him the reader is referred. See PAINTING *amongst the Ancients*.

Amongst the best established maxims, relating to chiaro-scuro, are the following:

That there should be one principal light in every picture; that other lights may, and ought to be admitted, but that they should at all times, be either less in quantity or lower in tone, than the great principal light; that this principal light should either be placed on the most important object in the picture, or be so managed, as to conduct the eye of the spectator to that object; that, independent of the forms of the objects and groups themselves, each mass of light, and dark, should in itself be of an agreeable shape; and that these masses should be so linked, as it were together, that no body, either of light or dark, may appear like a spot unconnected with the rest.

One thing more should be observed. Although, as has been before said, the system of Lionardo da Vinci, of constantly opposing a shade to a light, produces a poverty of effect; yet it gives a zest and appearance of truth to a picture, to introduce, in some small part of it, a figure, or other object, relieved at once, by dark on a light ground.

For further information, respecting clair-obscure, the reader is referred to Sir Joshua Reynolds's Lectures, and to his Notes on Mr. Mason's Translation of Du Fresnoy's elegant poem on painting; where the subject, with the one exception we have taken the liberty to make, is treated with a perspicuity, the result of deep investigation and long professional experience.

Although a knowledge of the chiaro-scuro is generally considered as necessary to the painter alone, yet the fine effects produced by it are well worthy the consideration of the sculptor and the architect. The sculptor who, when modelling his design, avails himself not of the direction or peculiarities of the light afforded by the situation where his group, his statue, or basso-relievo is to be placed, loses one of the greatest advantages afforded by his art. Michael Angelo's fine figure of Lorenzo da Medici in the sagresty of St. Lorenzo at Florence, and some of Bernini's monuments in St. Peter's at Rome, would forfeit half their claim to our admiration if removed to a light different from that for which they were composed.

Observations of the same tendency might be made respecting architecture; the fine chiaro-scuro occasioned by the intercolumniation, and the broad projecting pediments of the temples of Pestum, and the church of Covent Garden, leave the grandest impressions on the mind of every beholder. See SCULPTURE and ARCHITECTURE.

CHIARO-SCURO, is also used to denote a species of engraving, said to have been discovered by Ugo di Carpi, an Italian painter at the commencement of the 16th century; in which he was followed by Andrea Andriani of Mantua, and others; but the Germans, and apparently with some reason, dispute with the Italians the honor of the invention. These prints are produced by three distinct impressions from the same number of blocks of wood; the first gives the outline, the second, the middle tints, and the third, the shadows; so that the print, when complete, resembles a drawing in bistre upon a tinted paper, and touched with white.

CHIARO-SCURO is likewise used to signify those pictures which are painted with different shades of the same colour only. Of this class are the fine friezes, by Polidor, and others, on the façades of the palaces at Rome, and other cities of Italy; and the ingenious imitations of cameos and basso-relievos, with which so many painters in distemper have ornamented the interior of magnificent dwellings.

For the illustration of this article see the following plates, *viz.*

1. The simple principles of Chiaro-Scuro illustrated.
2. The conduct of Correggio in the distribution of his masses

maſſes of light and ſhade, exemplified in one of his compoſitions in the Duomo at Parma.

3. An example of Rubens.

4. A ditto of Rembrandt.

CLAIRVAUX, in *Geography*, a town of France, in the department of Jura, and chief place of a canton in the diſtrict of Lons-le-Saulnier, 3 leagues S.E. of it. The place contains 1210, and the canton 7226 inhabitants; the territory includes 160 kiliometres and 33 communes.—Alſo, a town of France, in the department of the Aube, and diſtrict of Bar-ſur-Aube, which took its name from an abbey built there in the year 1115; 2 leagues S. of Bar-ſur-Aube.

CLAIRVILLE, St. a ſmall ſettlement of America, in the ſtate of Ohio, and county of Belmont, 12 miles from the river Ohio, on the poſt road from Wheeling to Kentucky.

CLAISE, a river of France, which runs into the Creuſe near La Haye.

CLAIX, a town of France, in the department of the Iſere, and diſtrict of Grenoble; 4 miles ſouth of Grenoble.

CLAKIS, in *Ornithology*, a name given by the people of Lancaſhire, and ſome other places, to the BARNACLE, a ſmall ſpecies of wild gooſe; the *Anas erythropa*, or *Anas cinerea, fronte alba*, of Gmelin. It is found in Hudſon's Bay, and the N. part of Europe, and in winter in England.

CLAM, in *Geography*, a town of Germany in the archduchy of Auſtria, 1 mile W. of Gran.

CLAM *town*. See EGG *harbour*.

CLAMATOR, in *Antiquity*, was uſed to ſignify a domeſtic officer, whoſe buſineſs was to call the gueſts to dinner.

CLAMEA *admittenda in itinere per attornatum*, in *Law*, is a writ whereby the king commands the juſtice in eyre to admit a perſon's claim by an attorney, who, being employed in the king's ſervice, cannot come in perſon. Reg. Orig. 19.

CLAMECY, in *Geography*, a town of France, in the department of the Niévre, and principal place of a diſtrict, at the conflux of the Beuvron and the Yonne. The nominal biſhop of Bethlehem reſided in the fauxbourgs of this town; the ſee having been fixed here from the time when the Chriſtians were expelled the Holy Land; his revenue was ſmall, and his dioceſe limited to the place of his reſidence; 11 leagues N.N.E. of Nevers, and 7 ſouth of Auxerre.

CLAMOR, or CLAMEUR *de Haro*, a popular term in the French laws, importing a complaint, or cry, whereby any one implores the aſſiſtance of juſtice againſt the oppreſſion of another.

CLAMOR, *βοη*, in *Medicine*, an intenſeneſs of the voice, or a loud outcry. This is ſometimes the cauſe of a rupture of the veſſels, and ſometimes of a diſorder, like an inflammation about the membranes of the fauces and muſcles; which may be compared to that ulcerous and inflammatory laſſitude, which affects the hands, legs, and loins, after exceſſive hard labour; the ſpirituous and humid particles being exhauſted, and the fibres and membranes dried and contracted. A clamor is ſometimes alſo a ſort of remedy, and preſcribed as ſuch in order to rouſe perſons out of a lipothymy, or ſyncope.

CLAMOR *bellicus*. See CHARGE and SHOUT.

CLAMPS, in *Gunnery*. See CAP-*ſquares* and CANNON.

CLAMPS, in *Ship Building*, are ſtrakes of plank, in large ſhips, on the gun-deck, eight or nine inches thick, fayed to the ſides, to ſupport the ends of the beams.

CLAMP-*hanging*, may be fixed to any place in the ſide of a ſhip for faſtening ropes to, in order to ſuſpend the ſtages for the workmen, &c.

CLAMPS, in a *Ship*, are alſo pieces of timber applied to a maſt, or yard, to ſtrengthen it, and prevent the wood from burſting.

CLAMP is alſo a crooked iron plate, faſtened to the after end of the main cap of ſnows, to ſecure the try-ſail maſt.

CLAMP, alſo denotes a little piece of wood, in form of a wheel; uſed inſtead of a pully in a mortice.

CLAMP, is likewiſe the term for a pile of bricks built up for burning.

CLAMP-*nails*, are ſuch nails as are uſed to faſten on clamps in building and repairing of ſhips.

CLAMPETIA, in *Ancient Geography*, a town of Italy, in Magna Græcia, in the country of the Brutians. It is placed by M. D'Anville S.W. of Conſentia, and is the modern Amamea.

CLAMPING, in *Joinery*, &c. When a piece of board is fitted with the grain, to the end of another piece of board croſs the grain; the firſt board is ſaid to be clamped. Thus the ends of large old tables were commonly clamped, to preſerve them from warping.

CLAMPONNIER, or CLAPONNIER, in the *Manege*, a long-jointed horſe; that is, one whoſe paſterns are long, ſlender, and over-pliant. The word is obſolete, and is properly applicable only to the ox kind; for *la claponniere* in French, is in them what the paſtern is in a horſe.

CLAN, a term uſed in Scotland to denote a number of families of the ſame name, under a feudal head or chief, who protected them, and, in return for that protection, commanded their ſervices as his followers, and led them to war, and on military excurſions.

The diviſion of the country into clans, had no ſmall effect in rendering the nobles conſiderable. The nations which overrun Europe, were originally divided into many ſmall tribes; and when they came to parcel out the lands which they had conquered, it was natural for every chieftain to beſtow a portion, in the firſt place, upon thoſe of his own tribe or family. Theſe all held their lands of him; and as the ſafety of each individual depended on the general union, theſe ſmall ſocieties clung together, and were diſtinguiſhed by ſome common appellation, either patronymical or local, long before the introduction of ſurnames, or armorial enſigns. But when theſe became common, the deſcendants and relations of every chieftain aſſumed the ſame name and arms with him; other vaſſals were proud to imitate their example, and by degrees they were communicated to all thoſe who held of the ſame ſuperior. Thus clanſhips were formed; and in a generation or two, that conſanguinity, which was at firſt in a great meaſure imaginary, was believed to be real. An artificial union was converted into a natural one; men willingly followed a leader, whom they regarded both as the ſuperior of their lands, and the chief of their blood, and ſerved him not only with the fidelity of vaſſals, but with the affection of friends. In the other feudal kingdoms, we may obſerve ſuch unions as we have deſcribed, imperfectly formed; but in Scotland, whether they were the productions of chance, or the effect of policy, or introduced by an Iriſh colony, and ſtrengthened by carefully preſerving their genealogies, both genuine and fabulous, clanſhips were univerſal. Such a confederacy might be overcome, it could not be broken; and no change of manners or of government has been able, in ſome parts of the kingdom, to diſſolve aſſociations which are founded upon prejudices ſo natural to the human mind. How formidable were nobles at the head of followers, who, counting that cauſe juſt and honourable which their chief approved, were ever ready to take the field at his command, and to facrifice their lives in defence of his perfon, or of his fame? Againft fuch men a king contended with great difadvantage; and that cold fervice, which money purchafes, or authority extorts, was not an equal match for their ardour and zeal. Robertfon's Hift. Scotland, vol. i. p. 27, 28.

CLANBRASSIL, in *Geography*, the name of an old territory in Ireland, part of the prefent county of Armagh, which has been retained in the Irifh peerage. It is formed of the Irifh word *clann*, (often called *glen* or *glan*), and the family name of the tribe that inhabited it.

CLANCARTHY, (fometimes called *Clancare* and *Glencare*,) is a name formed like the preceding, from M'Carthy more ni Carra, a very powerful nobleman in the counties of Cork and Kerry, Ireland, whofe defcendant was made an earl with this title by queen Elizabeth. It is at prefent the title of the family of Trench.

CLANCULARII, in *Ecclefiaftical Hiftory*, a fect of Anabaptifts who denied the neceffity of making an open profeffion of the faith; and taught that a private one would be fufficient. Thefe were called alfo Hortulani and Gardeners, from the places they chofe to affemble in, inftead of churches.

CLANDESTINA, in *Botany*, Tourn. See LATHRÆA *Clandeftina*.

CLANDESTINE, any thing done fecretly, and without the knowledge of fome of the parties interefted in it; or without the proper folemnities.

The word comes from the prepofition *clam*, of κλειω, *claudo*, *I fhut*; or κλεμμα, *furtum*, *theft*.

Thus a marriage is faid to be clandeftine, when performed without the publication of banns, the confent of parents, or the knowledge of the ordinary. The council of Trent, and the French ordonnances, annul all clandeftine marriages. See MARRIAGE.

CLANDON COLLIERIES, in *Geography*, are coal-pits in Somerfetfhire, to which a rail-way is conducted from the Radftock line of the Somerfetfhire coal canal. See CANAL.

CLANEBOYS, the name of two diftricts in Ireland, one in the county of Antrim, and the other in that of Down, which belonged to the O'Neils, and are often mentioned in Irifh hiftory. They are alfo called Clan-Hugh-boy, from Hugh boy O'Neil, the leader of the Sept when they conquered thefe territories on the death of William de Burgho, earl of Ulfter, in 1333. Leland—O'Brien.

CLANEUS, in *Ancient Geography*, an epifcopal town of Afia, in Galatia Salutaris; called alfo Clangis.

CLANGULA, in *Ornithology*, the *Anas* of Gmelin's Linnæus: varied with black and white, with a tumid violaceous head, and a white fpot at the opening of the mouth; the fmall reddifh-headed duck of Willughby and Ray; the golden eye of Pennant and Latham; and the garrot of Buffon. See ANAS.

CLANIS, in *Ancient Geography*, *La Chiana*, a river of Italy, in Etruria. This river, called by the Greeks Glanis, was formed by the union of a great number of ftreams and torrents which defcended from the mountains; and when they became ftagnant in their courfe, they produced fmall lakes near Clufium. The river ran towards the Tiber.

CLANIS, or CLANIUS, a river of Italy in Campania. It rofe in the mountain of Abella, and difcharged itfelf into the fea near Patria.—Alfo, a river of Spain.

CLANMAURICE, in *Geography*, a name given to one of the baronies in Kerry, that originally belonged to Maurice fon of Raymond le gros, a companion of Strongbow's, from whom are defcended the Fitzmaurices, earls of Kerry, and the prefent marquis of Lanfdown.

CLANRICKARD, (originally Clanrichard) a territory in Connaught, belonging to one branch of the family of Bourke, or Bourgho, the defcendant of which is at prefent earl of Clanrickard.

CLANRICKARD, ULIAC, earl, and afterwards marquis of, in *Biography*, was the moft refpected, moft powerful, and moft effectual friend of Charles I. and the government in the weft at the beginning of the rebellion of 1641. He was deputy to the marquis of Ormond, whom the king had appointed lord lieutenant, and after uncommon exertions in the royal caufe, he was at laft obliged to leave Ireland. Lord Clanrickard wrote memoirs of the tranfactions in which he bore fo confpicuous a part. Lord Clarendon refers to thefe as giving fuch a full relation of all material circumftances as to render it unneceffary for himfelf to enter into detail. Bifhop Nicholfon, however, in his hiftorical library, confiders the publication under the name of the memoirs, &c. of the marquis of Clanrickard as "a lean collection of letters, warrants, orders, and other loofe and incoherent ftate papers;" and blames the anonymous editor as wifhing "to lay moft of the bloodfhed of thefe difmal times at the door of the Englifh proteftants." As the authenticity of the papers is not difputed, they will of courfe be examined by thofe who wifh to know the melancholy events of that time. The marquis died in 1659 before the king's reftoration. Leland. Nicholfon.

CLANUM, in *Ancient Geography*, a town of Gaul, in the environs of Arelate, between Cabellio and Ernuginum. Anton. Itin.—Alfo, a town of Gallia Lyonnenfis, on the road from Caracotinum to Auguftobona, between Agredinum and Auguftobona.

CLANWILLIAM, in *Geography*, the name of two baronies in Ireland; one in the county of Limerick, and the other in the county of Tipperary. The laft gives the title of earl to the noble family of Meade.

CLAP, in *Surgery*, a vulgar name for Gonorrhœa, a puriform difcharge from the urethra in men, and from the vagina in females. See BLENNORRHAGIA and GONORRHŒA. Dr. Samuel Johnfon derives the word *clap*, from the old French term *clapoir*; but we rather incline to believe it is of Saxon or German origin; *die klepperinn*, in German, fignifies a lewd woman or proftitute.

CLAP-*board*, a board cut, in order to make cafks or veffels.

CLAP-*net*, in *Birding*, a fort of net contrived for the taking of larks with the looking-glafs, by the method called daring, or doring. The nets are fpread over an even piece of ground, and the larks are invited into the place by other larks faftened down, and by a looking-glafs compofed of five pieces, and fixed in a frame, fo that it is turned round very fwiftly, backwards and forwards, by a cord pulled by a perfon at a confiderable diftance behind a hedge. See DORING.

CLAPHAM, in *Geography*, a village in Suffex, a rectory in the rape of Arundel, fituate near the edge of the clay and fand covering the chalk of the South-Downs. The fituation of the fteeple of its church was determined in the government trigonometrical furvey in 1792, by an obfervation from Chanctonbury Ring ftation diftant 27,201 feet; and another from Rook's Hill ftation diftant 68,929 feet, and bearing 75° 30′ 37″ N.W. from the parallel to the meridian of Dunnon; whence are deduced, its latitude 50° 50′ 38″ N. and longitude from Greenwich 27′ 45″ W. or 1^m 50^s.9 in time.

CLAPHAM-*Common obfervatory*, belonging to Mr. Cavendifh; the exact fituation of the tall pole or objects affixed over this gentleman's tranfit-room, was determined in the government trigonometrical furvey in 1787, by an obfervation from

from Hundred-Acres ftation diftant 43,351 feet, and bearing 13° 45′ 28″ S.W. from the parallel to the meridian of Greenwich; and another from Severndroog Tower diftant 47, 295 feet; whence are deduced its latitude 51° 27′ 13″ N. and longitude from Greenwich 8′ 40″ W. or 34ˢ.7 in time; alfo, that this obfervatory bears 26° 29′ 52″ W. from the S. meridian of the crofs on St. Paul's cathedral, diftant 24,563 feet.

CLAR, or CLAER, in *Metallurgy*, bone afhes perfectly calcined, and finely powdered, kept purpofely for the covering of the infides of COPPELS.

CLAR, ST. in *Geography*, a town of France, in the department of the Gers, and chief place of a canton in the diftrict of Lectoure; the place contains 1290 and the canton 8509 inhabitants; the territory includes 160 kiliometres and 16 communes.

CLARA, a fmall poft town on the river Brofna, in the King's County, Ireland; 53 miles weft from Dublin.

CLARA, LA, a town of the ifland of Cuba; 18 miles N.W. from Spirito Santo.

CLARA, or MEL, an ifland in the Indian Sea, near the coaft of Siam; 25 miles long and 4 wide. N. lat. 11° 4′. E. long. 97° 50′.

CLARAC, a town of France, in the department of the Lower Pyrennées, and chief place of a canton in the diftrict of Pau; the place contains 233 and the canton 9194 inhabitants: the territory comprehends 125 kiliometres and 15 communes.

CLARAMONT *powder*, the name of a medicinal powder, very famous in Venice, and fome other places, for its virtues in ftopping hæmorrhages of all kinds, and in the cure of malignant fevers. It has its name from the perfon who firft found out its virtues, and who has written a book exprefsly about it. It is a white earth found near Baira, not far from Palermo, and is thence called alfo by fome writers, *terra de Baira*.

CLARATUMBA, in *Geography*, a town of Poland, with a celebrated abbey, in the palatinate of Cracovia; 4 miles E. of Cracow.

CLARE, a county of Ireland in the province of Munfter, fituated on the weftern coaft. It was anciently called Thomond, which implies *North Munfter*, and was a kingdom or principality under the O'Briens, defcendants of Brien Boromhe, the king of Ireland, who was flain, fighting againft the Danes, in the battle of Clontarf, A.D. 1014. One of the family was acknowledged as king of Thomond by Henry III.; and Murrough O'Brien was made earl of Thomond by Henry VIII. on refigning his old title of prince, and receiving a new grant of his lands from that monarch. Such agreements were then common, the petty Irifh princes hoping thus to preferve their poffeffions, and the Englifh fovereigns wifhing to conciliate them; but the plan did not anfwer. The title of Thomond has continued, with fome fhort intervals, in the O'Brien family. Thomas de Clare, fon of the earl of Gloucefter, having come to Ireland in 1276, and married a daughter of the earl of Defmond, fettled in this county. Some accounts ftate, that a large portion of it was beftowed on him by Brien Inath, king of Thomond, on condition of receiving affiftance to regain his authority, which had been ufurped by another branch of the family. Other accounts fay, that this diftrict was given to De Clare by Edward I.; and it is not unlikely that he procured from the latter a confirmation of the grant of the Irifh prince. This Thomas de Clare, and his fon or brother Richard, built fome caftles and an abbey, and from them the county received its prefent name. Thomond, as its name implies, had always been confidered as a part of Munfter; but when Connaught was divided into counties in 1562, Clare was added to it. At that time each province had a peculiar governor, called lord-prefident, and as the earls of Thomond had poffeffions in other parts of Munfter, and were moftly connected with it, they naturally wifhed Clare to be part of that province, which, on petition, was effected in 1602. Some have fuppofed that it ought to be reckoned in Connaught, becaufe it is on the fame fide of the Shannon; but the eafieft accefs to it was through Limerick, the environs of which city extend into it, and its bifhopric is under the primate of Munfter.

Clare is bounded on the north by the county of Galway, on the eaft and fouth by the Shannon, which divides it from the counties of Tipperary, Limerick, and Kerry, and on the weft and north-weft by the Atlantic Ocean and the bay of Galway. It extends from north to fouth 33 miles (42 Englifh), and from eaft to weft 52 (66 Englifh), containing 476,200 acres (765,042 Englifh), or about 744 fquare miles (1195 Englifh). It is divided into nine baronies, and 79 parifhes, moft of which are in the united fees of Killaloe and Kilfenora. Thefe 79 by unions, form only 30 benefices, and only 19 of them had churches, when Dr. Beaufort publifhed his memoir. The number of houfes in the official return of 1791 was 17,396, according to which the population may be eftimated at 104,000. Three members reprefent it in the Houfe of Commons, two of whom fit for the county, and one for the borough of Ennis.

The county of Clare confifts of extenfive tracts of ground of various quality; much of fattening and meadow ground; much of light limeftone pafture, fit for rearing fheep and young cattle; much arable land; extenfive bogs, and fome mountain. The lands called *Corcaffes*, confifting of about 20,000 acres, along the Fergus and Shannon, are faid by Mr. Young to be peculiarly fit for fattening bullocks, 4000 of which were then annually fattened on them; and the ftore cattle of Clare are at prefent more numerous than in the adjoining counties. The foil of the Corcaffes is defcribed by that intelligent traveller as either a rich black loam, or a deep rich blue clay; whilft the higher lands are limeftone or limeftone-gravel. The bogs near the Shannon are valuable on account of the fupply of turf they furnifh for the Limerick market; and thofe in the interior, though they do not fet fo high, fupply fuel to the neighbouring inhabitants. The worft grounds are the eaftern mountains, the peninfula north of the Shannon, and the barony of Burren. This laft is exceedingly rocky, but its rocks are limeftone, and fuch is the luxuriance of the pafturage interfperfed among them, that thefe feemingly barren hills fupport a great number of cattle and very large flocks of fheep. The other tracts of mountain are generally gritftone. Mr. Young ftates the average rent of the Corcafs lands at 20*s*., and the average rent of the whole county at 5*s*. per acre, in 1776. An intelligent proprietor of part of the Corcafs lands has informed the writer, that they now fet at from 3 guineas to 5 guineas per acre; and he fuppofes the average rent of the whole county not lefs than 30*s*. Rape is fown in confiderable quantities in mountain or boggy grounds, both of which are burned for it. Some of the rape feed is preffed into oil at mills near Killaloe, and the rape cakes fent to England for manure; but the greater part is exported to England, where it is preffed for the ufe of the woollen manufacturers in Yorkfhire. One houfe in Limerick fhipped the laft feafon (1805), near 5000 barrels of rape-feed, value above 10,000 pounds; but it is cultivated in the counties of Limerick and Tipperary as well as in Clare. Beans were grown in large quantities, when Mr. Young was in Clare, but the cultivation has been laid afide, as they are no longer ufed

ufed for bread by the peafantry. Flax is fown in fmall quantities for home confumption, but fpinning is not general, and fcarcely a remnant of the manufacture of the excellent Clare dowlafs now exifts. The only manufactures, indeed, for which there is a market, are coarfe flannels and worfted ftockings, which are chiefly fold at Ennistymon, on the weftern coaft.

Mr. Young has fpoken in high terms of the cider orchards of this county. Since he wrote, in a time of fcarcity they were very generally deftroyed; but the price of cider being much increafed, and the mode of making it much improved, they are now attended to, and in good keeping. The cacagee apple is peculiarly efteemed, but the trees being bad bearers, it is fcarce.

The whole weftern coaft of Clare does not afford one harbour in which fhips may lie in fafety, and its little ports on the Shannon can never rival Limerick. The only rivers that deferve notice are the Shannon and Fergus. The former of thefe, when it firft reaches the fhores of Clare, is expanded into Lough Deirgheart; but its breadth is contracted as it approaches Killaloe. Between Clare and Kerry the breadth of this noble river varies from one mile to five. The Fergus, the principal river rifing in Clare, is of no importtance, floops only being capable of navigating it. Its eftuary, however, at its junction with the Shannon, is very wide and full of iflands. This river and feveral others in Clare, dip under ground in fome part of their courfe.

There are in this county many *turlachs*, *i. e.* fpots which at one time are lakes, and at another found fheep-walks. Of thefe, that at Kilcorney, in Burren, is moft remarkable, the waters iffuing, frequently more than once a year, from a fpacious cave, and deluging the adjacent flats. There are fome lakes, but none very confiderable.

The county town is Ennis on the Fergus, and it is the only town of note in the county. The Ogham infcription on Callan Mount, (fee CALLAN), and feveral ruins, particularly thofe of Quin Abbey, (fee ARDSALLIS), and the ifland of Inis Scattery, render this county interefting to the antiquarian, whilft the plants and minerals with which its mountains and ftony parts abound, make it equally deferving the attention of the botanift and mineralogift.

The following plants found in Clare, are reckoned, by profeffor Wade, amongft the *plantæ rariores* of Ireland; *viz.* Iris fœtidiffima, Afperula cynanchiea, Lyfimachia vulgaris, Arbutus uva urfi, Butomus umbellatus, Sedum telephium, Potentilla fruticofa, Rubus faxatilis, Dryas octopetala, Mentha pulegium, Turrites hirfuta, Cardamine bellidifolia, Cheiranthus finuatus, Gnaphalium dioicum, and Satyrium hircinum. An intelligent botanift, who is employed by the provoft and fellows of Trinity College, Dublin, vifited Clare in the autumn of 1805; but the refult of his refearches has not yet been made public.

The mineralogy of Clare is very little known. Mr. Donald Stewart, the itinerant mineralogift of the Dublin Society, has, however, mentioned fome particulars. Lead ore is faid to occur in various places; in fome of which it was formerly raifed and fmelted. Manganefe is abundant; and there are different ores of iron, particularly micacious iron ore, or *eafingman*, and red iron-ftone. Boate mentions iron-works, belonging to Englifh merchants, in Clare, previous to the rebellion of 1641. Thefe probably contributed to its being fo bare of timber. At Doolin in Burren there has been found a vein of purple fluor fpar, fimilar to that brought in ornaments from Derbyfhire. Some of the fpecimens have cubic cryftals; but the extent of the vein is not known, and no attempt has been made to apply it to any ufeful purpofe. Beaufort, Young, &c. &c.

CLARE, a poft-town of the county of Clare, Ireland, on the river Fergus, which is navigable to it for fmall veffels, and about two miles S. from Ennis, which was alfo formerly called Clare. Between the two towns are the ruins of Clare abbey. It is 114 miles S.W. from Dublin.

CLARE, a river of the county of Galway, Ireland, flowing into Lough Corrib. On this river is a fmall fair-town of the fame name, from which the barony of Clare is called.

CLARE, the name of a high rocky ifland belonging to the county of Mayo, Ireland; fituated at the entrance of Clew bay. It is about four miles long, but of very unequal breadth; and it affords good anchorage for fhips in moderate weather. W. long. 9° 49′ from Greenwich. N. lat. 53° 49′.

CLARE, an ifland lying fouth of the county of Cork, Ireland, on which is the moft fouthern point of Ireland, generally known by the name of Cape Clear. This ifland, in Smith's time, contained about 400 families, which its produce was fcarcely able to fupport. The men are all fifhermen, and they are good pilots. It is about three miles long, and nearly one wide. W. long. 9° 23′ from Greenwich. N. lat. 51° 21′. Smith.

CLARE, at prefent an unpaved and inconfiderable market town in the county of Suffolk, England, was once a place of importance, and contains the ruins of a ftrong caftle. Gilbert de Clare, founded a Benedictine monaftery here in 1090, which was removed in 1124, by his fon Richard, to Stoke, near Clare, after which, Edmund Mortimer, earl of March, converted it into a college for fecular priefts, who were governed by a dean, and fix prebendaries. Archbifhop Parker was dean of this foundation in 1545, the date of its diffolution. There was, befides, a priory of monks of the order of St. Auguftine, founded probably by Richard de Clare in 1248, who introduced that order into England: the monaftic buildings were recently inhabited by a farmer, and the chapel is now a barn. Exclufive of the founder, Joan of Acres, Lionel, duke of Clarence, with his wife, and Edward Monthermer, earl of Gloucefter and Hereford, were buried in the priory chapel. The large and handfome parifh church is fuppofed to have been built by an abbot of Bury. The civil and fpiritual courts are held at Clare, and it gave the title of marquis to the dukes of Newcaftle of the Holles family, as it afterwards did to thofe of the Pelham. Without, and eaftward of the town, is a large barrow. There are two annual fairs, the market day is Tuefday, and it is 56 miles N.E. from London.

CLARE, a townfhip on St. Mary's bay, in Annapolis county, Nova-Scotia. It has about 50 families, and confifts of woodland and falt-marfh.

CLARE. See *St.* CLAIR.

CLARE, *Nuns of St.* in *Ecclefiaftical Hiftory*, were founded at Affife in Italy, about the year 1212. Thefe nuns obferved the rule of St. Francis, and wore habits of the fame colour with thofe of the Francifcan friars; and hence were called *Minoreffes;* and their houfe, without Aldgate, the *Minories*, where they were fettled when firft brought over into England, about the year 1293. They had only three houfes befides this.

CLAREMONT, in *Geography*, a townfhip of America, in Chefhire county and ftate of New Hampfhire, on the E. fide of Connecticut river, oppofite to Afcutney mountain in Vermont, and on the N. fide of Sugar river; 24 miles S. of Dartmouth college, and 121 S.W. by W. of Portfmouth. It was incorporated in 1764, and contains 1889 inhabitants.

CLAREMONT, a county of America, in the ftate of S. Carolina and diftrict of Camden, containing 2479 white inhabitants, and 2110 flaves. The county-town is Statefburg.

CLARENCE,

CLARENCE. See CHIARENZA.

CLARENCEUX *King of Arms*, in *Heraldry*, the second officer in the college of arms. It is uncertain when this office, which is held by patent under the great seal during good behaviour, was first created. It is stated by some authors to have been instituted by Edward III., by others, by Henry V.; who, they say, preferring the herald of his brother Thomas, duke of Clarence, constable of the army, created him a king of arms by the title of Clarenceux, (in Latin Clarentius) and placed the south part of England under his province. After Henry VI. it sunk into the office of a herald, but was again restored to the rank of a king of arms by Edward IV.

The official seal of Clarenceux is argent, a cross gules, on a chief of the second a lion passant guardant, crowned with an imperial crown or, and is borne on the dexter side impaled with his paternal coat. The badge, which is worn pendant from a gold chain, is enamelled with the above arms, surmounted by the crown of a king of arms on a green ground on one side, and on the reverse, the royal arms on a white ground. He wears a collar composed of S. S. of silver gilt. See COLLAR.

The coronet of a king of arms is composed of a plain circle of gold, thereon 16 strawberry leaves, eight of which are higher than the rest, and round the rim the motto "Miserere mei Deus secundum magnam misericordiam tuam."

His tabard is of velvet, thereon embroidered the king's arms, embossed in gold and silver.

CLARENDON, in *Geography*. See *Cape* FEAR *River*.

CLARENDON, a county of America, lying in the Sumpter district, in the state of S. Carolina, about 30 miles long and 30 broad, containing 2333 inhabitants.

CLARENDON, a township of America, near the centre of Rutland county, Vermont, watered by Otter creek, and its tributary streams; 14 or 15 miles E. from Fairhaven, and 44 N.E. from Bennington. It contains 1764 inhabitants. On the S.E. side of a mountain, in the westerly part of Clarendon, is a curious cave, 2½ feet in diameter at its mouth, and nearly the same through its whole length of 31½ feet; but at this distance from the mouth it opens into a spacious room, 20 feet long, 12½ wide, and 18 or 20 feet high. The floor, sides, and roof appear to consist of a solid rock, which is rough and uneven. The water percolating through the top has formed stalactites of various forms, some conical, and others having the appearance of massive columns. This room communicates by a narrow passage with others equally curious. Morse.

CLARENDON, a parish of Jamaica, in the county of Middlesex, the low lands of which are favourable for plantation of tobacco. In 1789 the number of sugar-plantations in this parish was 56, and that of negroes 10,150.

CLARENDON *Fort*, a fort on the W. coast of the island of Barbadoes in St. James's parish; 1¾ mile S. from Speight's town.

CLARENDON, *Constitutions of*, in *Antiquity*, a charter or code of laws established by the parliament at Clarendon in Wiltshire, A. D. 1164; sixteen articles of which related particularly to ecclesiastical matters, and were designed by king Henry II. to check the power of the pope and his clergy, and to limit the total exemption which they claimed from the secular jurisdiction. The substance of them is as follows: 1. All pleas between clergymen and laymen shall be tried in the king's courts. 2. Churches in the king's gift shall not be filled without his consent. 3. All clergymen, when accused of any crime, shall be tried in the king's courts; and when convicted, shall not be protected from punishment by the church. 4. Clergymen shall not go out of the kingdom without the king's leave. 5, 6, Regulate the manner of proceedings in the ecclesiastical courts. 7. None of the king's ministers or vassals shall be excommunicated without his knowledge. 8. Appeals from the archbishop to be made to the king. 9. Pleas between a clerk and a layman, whether an estate was in free-alms or a lay-fee, to be tried in the king's court by a jury. 10. One of the king's tenants might be interdicted, but not excommunicated, without the consent of the civil judge of the place. 11. All prelates, who hold baronies of the king, shall perform the same services with other barons. 12. The revenues of vacant sees and abbeys belong to the king. The election of prelates shall be with the king's consent; and they shall swear fealty, and do homage to the king, before their consecration. 13, 14, 15, Direct the manner of proceeding, in case any of the king's barons shall disseise any of the clergy of the lay-fees which they held under them. 16. The sons of villains shall not be ordained without the leave of their masters.

These constitutions were vehemently opposed by Becket, who, in a great measure, prevented their salutary effects. The king, however, by passing so many ecclesiastical ordinances in a national and civil assembly, fully established the superiority of the legislature above all papal decrees or spiritual canons, and gained a signal victory over the ecclesiastics. Apprehending that the bishops, though overawed by the present combination of the crown and the barons, would take the first favourable opportunity of denying the authority, which had enacted these constitutions; he resolved, that they should all set their seal to them, and make a promise to observe them. None dared to oppose his will, except Becket, who obstinately withheld his assent. At length, after much persuasion, and when he found himself deserted by all the world, even by his own brethren, he was obliged to comply; and he promised "legally, with good faith, and without fraud or reserve," to observe the constitutions; and he took an oath to that purpose. The king, thinking that he had now finally prevailed in this great enterprise, sent the constitutions to pope Alexander III. who then resided in France; and he required that pontiff's ratification of them. But Alexander, who, notwithstanding the most important obligations to the king, plainly saw, that these laws were calculated to establish the independence of England on the papacy, and of the royal power on the clergy, condemned them in the strongest terms; abrogated, annulled, and rejected them. There were only six articles, of the least importance, which, for the sake of peace, he consented to ratify. Becket repented of his assent, and redoubled his austerities by way of punishment for his criminality; and he refused to exercise any part of his archiepiscopal function, till he should receive absolution from the pope which was readily granted him. See the article BECKET.

CLARET, JOAN, in *Biography*, a Flemish painter, who lived about the year 1600, at Turin, where he painted many altar-pictures in a very bold and masterly style, little inferior to those of his cotemporary and friend Gio. Antonio Mulinari. Lanzi, Storia Pittorica.

CLARET, or *Clairet*, *pale red*, a name which the French give to such of their red wines as are not of a deep or high colour. See WINE.

The word is a diminutive of *clair*, *bright*, *transparent*. There are various accounts in the Phil. Trans. of attempts to improve the operation of tapping, by injecting the abdomen after the lymph is drawn off with claret and other astringents. Ibid. vol. xlix. part ii. N° 65. an. 1756.

CLARET, *Claretum*, in the *Ancient Pharmacy*, was a kind of of wine sweetened with sugar, and impregnated with aromatics; sometimes also called *Hippocras*, or *vinum Hippocraticum*; because supposed to have been first prescribed by Hippocrates. It has its name *claret* from its being clarified by percolation through a flannel bag, called *manica Hippocratis*.

Claret, in *Geography*, a town of France, in the department of the Hérault, and chief place of a canton, in the district of Montpellier; 5 leagues N. of Montpellier. The place contains 774, and the canton 1834 inhabitants: the territory includes 172½ kiliometres, and 10 communes.—Also, a town of France, in the department of the Lower Alps, and district of Sisteron; 11 miles N. of it.

Claret, in *Music*. See Clarion.

CLARIÆ, in *Ancient Geography*, a people of Thrace, placed by Pliny near the Danube.

CLARIAS, or Clarias *Nilotica*, in *Ichthyology*, the name of a fish of the *silurus* kind, common in the Nile, and brought to market at Memphis, and in many other parts of Egypt, but of an insipid taste, and eaten only by the poorer sort of people. The tail is broad and forked, and has externally two horny appendages of a round figure, and a hand's breadth in length, in which it differs from all other fishes. It is the *silurus clarias* of Gmelin. See Silurus.

Clarias is also the name given by Gronovius to the *Silurus anguillaris* of Gmelin. See Black-*fish*.

CLARICHORD. See Clavichord.

CLARIFICATION, is the separation, by chemical means, of any liquid from substances suspended in it, and rendering it turbid. If a difference can be made between clarification and filtration, it is, that the latter is effected by mere mechanical means, but the former either by heat or by certain additions.

The liquors, subjected to clarification, are generally solutions of animal on vegetable matter, in which the particles that produce the turbidness are so nearly of the same specific gravity with the liquor itself, that mere rest will not effect a separation. In these too the liquid is generally rendered thicker than usual by holding much mucilage in solution, which further entangles the turbid matter, and prevents it from sinking. Hence it is that vinous fermentation has so powerful an effect as a clarifier (wine being much more limpid than the grape, or other saccharine juice of which it is made), since this process always destroys a portion of saccharine mucilage, and generates alcohol, which is thin and limpid.

Coagulating fluids greatly assist clarification, when mixed with any turbid liquor; the process of coagulation entangling with it every thing which is simply suspended, and carrying it either to the top, in the form of a thick scum, or to the bottom, as a tough sediment, according to circumstances. Thus, to clarify muddy cider, the liquor is beaten up with a small quantity of fresh bullock's blood, and suffered to stand at rest for some hours; after which the liquor above is as clear as water, and almost as colourless, and at the bottom of the vessel is a thick, tough cake, consisting of the coagulated blood, which has carried down with it all the matter which rendered the cider turbid. Many albuminous and gelatinous substances act in the same manner. Of these the best known is white of egg, which, when used for this purpose, should be beat up cold with the liquor to be clarified, and afterwards, on applying a heat of about of 180°, the egg coagulates, and carries up with it all the opake particles of the fluid, in the form of a thick scum.

The first process of sugar-baking is carried on in this way either by white of egg or blood. The proportions required of these are always very small, compared to the quantity of the liquor to be clarified.

Mere heat will clarify liquors, when the substance that rendered them turbid is coagulable by heat; thus the juice of cabbage, and many other green vegetables, when heated, throw up a curdy green coagulum, and the remaining liquor is limpid and colourless.

Heat also assists in another way, in diminishing the specific gravity of liquors, which allows the coagulating matters to collect in a denser form, and thus to be more easily separable.

A most remarkable and unaccountable power is possessed by newly burnt charcoal, in clarifying all mucilaginous liquids, as already mentioned under the article Carbon.

Clarification is often found detrimental when used to prepare vegetable decoctions or infusions for medicinal purposes; and hence it is a much less frequent process in the Materia Medica than formerly.

Thus, if syrup of poppies be clarified till it becomes quite limpid, it loses almost all its narcotic power, and is, as a medicine, little better than simple syrup. (See also the article Filtration.)

Sugar is clarified with the whites of eggs, and sugar beat together with lime and with ox's blood, and with other materials. See Sugar.

For malt liquors, particularly beer, there are various methods of clearing; the best is by casting into it fixed nitre: some add the quintessence of malt and wine; whites of eggs made into balls with a little flour and isinglass: oil, and quintessence of barley, have the same effect. It is exceedingly cleared and strengthened by adding to it, during the time of its fermentation, some ardent spirit. See Ale, Beer, and Malt *liquor*.

CLARIFIERS, a name given to the copper pans or cauldrons fixed in a boiling-house, and used for the purpose of clarifying sugar. See Sugar.

CLARIGATIO, in *Roman Antiquity*, a ceremony that always preceded a formal declaration of war. It was performed in this manner; first four heralds, crowned with vervain, were sent to demand satisfaction for the injuries done to the Roman state. These heralds, taking the gods to witness that their demands were just, one of them, with a clear voice, demanded restitution within a limited time, commonly 33 days; which being expired without any restitution made, then the *pater patratus*, or prince of the heralds, proceeded to the enemies' frontiers, and declared war.

Clarigatio is also used for apprehending a man, and holding him to bail. The Greeks called this action androlepsia.

CLARIGATION, in the *Law of Nations*, denotes a loud, clear call, or summons made to an enemy, to demand satisfaction for some injury received; in defect whereof, recourse will be had to reprisals.

Clarigation amounts to much the same with what the Greeks call ανδροληψια. Though Naude uses the word in a somewhat different manner. "Reprisals," says he, "signify the same as *pignorationes Budæo, aut clarigationes Hermolao*: for, as to the Greek word *androlepsia*, it is equivalent to the Latin *pignorandi potestas*."

CLARINET, the name of a musical instrument, which has not been known in this country till within about 50 years ago, and which is said to have been invented about the close of the 17th century by John Christopher Denner, a wind musical instrument maker of Leipsic. This instrument has been found liable, by long use, to get out of tune by the widening of the bore, which is a fault that cannot afterwards be remedied. Messrs. Goulding and Co. of Pall-Mall, have lately obtained a patent for an improvement in the construction of this instrument. In order to prevent the inconvenience

venience above-mentioned, the patentees have conftructed an inftrument which is lined throughout with a tinned brafs tube, intended both to prevent the wood from decaying and to improve the tone of the inftrument. Another inconvenience arifing from the leathering of the keys, which was apt to be out of order in marching regiments, is remedied by lining the holes with a foft metal pipe ground perfectly flat upon the furface, to which a ftopper is fcrewed, that renders the pipe air-tight.

CLARINO, in the *Italian Mufic*, fignifies a trumpet; thus, *a duoi clarini*, added to any compofition, denotes that it was made for two trumpets. See Cornet and Trumpet.

CLARION, probably the *claret* of Lufcinius, a kind of trumpet, whofe tube is narrower, and its tone acuter and fhriller, than the common trumpet.

Menage derives the word from the Italian *clarino*, of the Latin *clarus*, by reafon of the clearnefs of its found. Nicod fays, the clarion, as now ufed among the Moors, and the Portuguefe, who borrowed it from the Moors, ferved anciently for a treble to feveral trumpets, which founded tenor and bafs. He adds, that it was only ufed among the cavalry and the marines.

Clarion, in *Heraldry*. Guillim fays clarions are a kind of old-fafhioned trumpets, others imagine they reprefent the rudder of a fhip, and others a reft for a lance.

CRARISIA, in *Botany*, Bofc. Nouv. Dict. Flor. Peruv. Pl. 28. Clafs and order, *diœcia diandria*.

Gen. Ch. *Male*. Catkins filiform, imbricated. *Cal.* a one-flowered fcale, containing two ftamens. *Female. Cal.* a very fmall fcale. *Pift.* Germ oval; ftyles two, awl-fhaped; ftigmas two. *Peric.* Drupe oval. *Seed* one. Two fpecies, both trees, are mentioned in the Flora Peruviana.

CLARISSIMI, among the Romans, a title of honour belonging to the third rank of nobility under the emperors. See Spectabiles.

CLARITAS Julia, in *Ancient Geography*, alfo called *Attubi* according to Pliny, a town of Spain, in Boetica.

CLARIUM, a fortrefs of Greece, in the Peloponnefus, fituate, according to Polybius, in the middle of the territory of Megalopolis.

CLARK-*goofe*, in *Ornithology*, a fpecies of wild goofe found in Zetland. Phil. Tranf. N° 473. fect. 8.

CLARKE, Samuel, in *Biography*, a minifter and writer of confiderable refpectability, was born in 1599, at Woolfton in Warwickfhire. He received his grammar education at Coventry, whence he removed to Emanuel college, Cambridge. When he had taken the degree of bachelor of arts, he left the univerfity, and after having acted for a fhort period as private tutor in a gentleman's family, he removed to Chefhire, and afterwards to Warwickfhire, in which counties he long officiated as a minifter with the greateft refpect and acceptance. On the publication of the *et cætera* oath he was one of the deputies chofen by the minifters of the diocefe of Worcefter to prefent a petition on their behalf to the king, Charles I., who was then at York. He was nominated to prefent a petition on the fame fubject to the parliament; and in 1660 he prefented an addrefs of thanks from the London minifters to Charles II., on his declaration refpecting ecclefiaftical affairs. He had this year been chofen minifter of St. Bennet's Fink in London, and in 1661 we find him named among the commiffioners of the Savoy for reforming the "Book of Common Prayer." At St. Bennet's Fink he continued in the diligent exercife of his profeffion, until the publication of the fatal act of uniformity, which turned him and about two thoufand others out of their places. After this meafure had been carried into effect, he did not altogether feparate from the eftablifhed church; but frequently attended its fervices both as a hearer and a communicant. He died on the 25th December 1682. He was a man of confiderable learning and extenfive reading; of plain, fimple, and unaffected manners; of exemplary piety and moral purity of life. He was an indefatigable ftudent, and a voluminous writer, as appears by the number and the extent of his publications. We fhall content ourfelves with naming the principal of them, which were his "Martyrology," "Lives of fundry Eminent Perfons," "Marrow of Ecclefiaftical Hiftory," and "Marrow of Divinity," all printed in folio.

Mr. Clarke had a fon of his own name, who was ejected from Grendon in Buckinghamfhire; he was the author of a work intitled "Annotations on the Bible," which has been highly fpoken of by Dr. Owen and Mr. Baxter. Clark's Narrative of his own Life. Calamy. Neal.

Clarke, Samuel, an oriental fcholar of the firft eminence, was born at Brackley, in the county of Northampton; and in 1638, when he was in the fifteenth year of his age, entered as a ftudent at Merton college, Oxford. Three years afterwards the city being garrifoned for the ufe of the king, he was obliged to leave the univerfity; but in 1648, after it had furrendered to the parliament, he returned, fubmitted to the vifitors they had appointed, and took the degree of mafter of arts. The year following he was defigned firft archi-typographus of the univerfity; to which was added the grant of the fuperior beadlefhip of civil law. He kept a boarding fchool at Iflington about the year 1650, and lent his affiftance towards the publication of the "Polyglot Bible." In 1658, however, he returned to the univerfity, was elected archi-typographus, and fuperior beadle of civil law, fituations which he continued to retain to the end of his life. His works confift of "Variæ Lectiones, et Obfervationes in Chaldaicam Paraphrafin," which appeared in the fixth volume of the "Polyglot Bible." "Scientia Metrica, et Rhythmica; feu Tractatus de Profodia Arabica ex Authoribus probatiffimis eruta." "Septimum Bibliorum Polyglotorum volumen, cum Verfionibus antiquiffimis, non Chaldaica tantum, fed Syriacis, Æthiopicis, Copticis, Arabicis, Perficis contextum." He made a tranflation from the original manufcript in the Cambridge public library, of "Paraphraftes Chaldæus in Libr. Paralipomenωn," a work which the learned Caftell fays he confulted in compofing his elaborate "Lexicon Heptaglotton." He reviewed alfo, with great care, the Hebrew text, the Chaldee Paraphrafe, and the Perfian Gofpels in the Polyglot Bible, and tranflated the laft into Latin. There is, befides, afcribed to him a Latin tranflation from the Hebrew, of a work entitled "Mafſeceth Beraioth, Titulus Salmudicus, in quo agitur de Benedictionibus, Precibus, et Gratiarum Actionibus, adjectâ Verfione Latinâ. In ufum Studioforum Literarum Talmudicarum in Æde Chrifti." He died near Oxford on the 27th of December 1669. Wood's Athenæ Oxon.

Clarke, Samuel, a learned divine of the eftablifhed church, was born at Norwich, in the month of October 1675; his father, Mr. Edward Clarke, was a gentleman of high refpectability in that city, one of its aldermen, and for fome years one of its reprefentatives in parliament. He received the firft part of his education at the free fchool of his native town, where he made a rapid progrefs in the acquifition of the learned languages. In the year 1691 he entered a ftudent at Caius college, Cambridge, and foon diftinguifhed himfelf by his ardent defire of knowledge, and by his unremitting diligence and fuccefs in the profecution of his ftudies. The fyftem of Des Cartes was at this time in high esteem, and taught with much zeal and confidence at the universities; but Mr. Clarke, even at this early age, had too much acuteness and penetration to mistake its fallacious inductions for demonstration, or its hypothetical fancies for sound philosophy. He had seen and carefully perused the Principia of Newton, then just published; and to his scrutinizing mind the more rational system; the more clear, solid, and conclusive reasonings of that great philosopher carried irresistible conviction. In the first ardour of his zeal for the principles he had newly embraced, and without regarding the deference which he knew to be due to the learning and talents of his respectable tutor, Mr. John Ellis, and to the other professors of the university, he performed a public exercise, with a view to his first degree, upon a question taken from the Principia, in the discussion of which he astonished his auditory by the clearness of his perceptions, and the solidity and force of his argumentation. Having thus become, upon enlightened conviction, a convert to the Newtonian system, he directed his thoughts to the best means of ensuring for it a more general reception. The work then in common use as a text-book was Rohault's System of Philosophy, upon Cartesian principles, which was written in very corrupt and barbarous Latin. Mr. Clarke, at the age of twenty-one, undertook the arduous, but commendable, task of making a more pure and classical translation of it; and he embraced this opportunity to disseminate his own system by subjoining to the original text a variety of such judicious and excellent notes as were calculated to lead the student, insensibly, to perceive the fallacy of the author's hypothesis. This plan produced its intended effect; Clarke's edition of Rohault, which passed through four editions, continued for some years the standing text-book of the university, until it undermined its own authority, and gave way to the publications of Rutherforth and Rowning, who were both avowedly the disciples of Newton. It being Mr. Clarke's design to take orders, he now directed his attention to the subjects more immediately connected with the sacred function. He began by studying the scriptures of the Old and New Testament in their original languages, and by carefully perusing the writings of the earlier Christian fathers, which contain much valuable matter relative to the principles and the evidences of Christianity. Shortly after he had been ordained he was introduced by Whiston to Dr. Moore, the bishop of Norwich, who was a warm friend to literature, and a great patron of learned men. Bishop Moore was so much pleased with Mr. Clarke, that on the collation of Whiston to the living of Lowestoffe, in the year 1698, he appointed him to be his domestic chaplain. In this situation he remained twelve years, enjoying every mark of the esteem and friendship of his learned patron, and associating with him on all occasions, rather with the intimacy of a brother than the distant reserve of a dependant. At his death, Dr. Moore evinced the confidence he had in him by entrusting to his care the entire management of his domestic affairs; it were almost superfluous to add that Mr. Clarke acquitted himself of his trust with honour and fidelity.

In the year 1699 he may be said to have commenced his literary career, as a divine, by the publication of "Three Practical Essays on Baptism, Confirmation and Repentance;" and also "Reflections" on a work entitled "Amyntor," known to be the production of Mr. Toland, and which related to the writings of the Primitive Fathers, and the Canon of the New Testament. These works of Mr. Clarke, although not to be ranked with his subsequent publications in point of literary merit, display the author's piety to great advantage, and show him to have been deeply versed in the writings of the earlier christians. As he was at this period intensely engaged in a critical study of the scriptures, he availed himself of the advantages he enjoyed, in the uncontrouled disposal of his time, and the free access allowed him to the valuable library of his patron, to impart the benefit of his labours to the public. In pursuance of this design he published, in the year 1701, a Paraphrase on the Gospel of St. Matthew, which was soon followed by Paraphrases on the Three Gospels of Mark, Luke, and John. These are plain, judicious, and learned expositions on the original text; and, being, in a great degree, free from the verbosity and circumlocution so common in works of a similar nature, may be read with great pleasure, and with great advantage, by all who seek their real improvement in christian knowledge and practice. It was originally the intention of the author to have carried on his undertaking through the whole of the books of the New Testament, and he had made some progress in the Acts of the Apostles, when other avocations, more urgent it should seem, diverted him from his purpose. Dr. Moore's great esteem and partiality for Mr. Clarke made him solicitous to advance him in his profession, by every means within his power and influence. He presented him with the rectory of Drayton, near Norwich, and obtained for him a parish in that city, which together produced a considerable addition to his income. At this time Mr. Clarke preached without notes, a practice in which, it is said, he was peculiarly happy, and which he continued until he removed to St. James's, where his more polite auditory induced him to read his discourses, and to compose them with every possible attention to method and style.

In the year 1704 Mr. Clarke's increasing reputation procured for him the appointment to preach Mr. Boyle's Lecture, and he chose for his subject the Being and Attributes of God. The general satisfaction which he gave, on this occasion, caused him to be reappointed the year following to the same office, when he delivered a course of sermons on the Evidences of Natural and Revealed Religion. These two courses were afterwards printed together, having been previously compressed and arranged into continued discourses, and passed through several editions with successive additions and improvements. The mode of reasoning pursued by Mr. Clarke, in proving the Being and Attributes of God, from arguments *à priori*, excited considerable attention on the appearance of his work, and led to much curious and interesting discussion. It was alleged against him that such reasoning was objectionable, as being too metaphysical and subtil for the generality of mankind to comprehend, and as, in many cases, inconclusive and unsatisfactory to the most cultivated and enlightened minds. It is to be observed, however, in justification of Mr. Clarke, that he has declared he did not himself consider the arguments *à priori* to be equally forcible and demonstrative with those which might be drawn from the works of creation, on the evidence of which he considered that the belief in the existence of God must ultimately rest. Nevertheless he thought, that as unbelievers had made great use of the arguments *à priori* on the other side of the question, in support of their atheistical tenets, it were highly desirable and proper that they should be met on their own ground, that the world might see, in the most striking point of view, the fallacy of their deduction, and that the being of God was proved, almost to demonstration, by the very mode of argumentation employed by them to infer his non-existence. So far as this Mr. Clarke's explanation is satisfactory; and must be admitted

mitted to hold him very free from meriting the wafpifh and illiberal reflection caft upon his labours by Pope, in the following lines of his Dunciad:

> "Let others creep by timid fteps and flow,
> On plain experience lay foundations low;
> By common fenfe to common knowledge bred,
> And laft to nature's caufe through nature led.
> We nobly take the high *priori* road,
> And reafon downward till we doubt of God."
> B. 4. line 455, &c.

Mr. Clarke has executed his undertaking with great ability; and has deferved well of the friends of religion for having fet this particular proof of the exiftence of God in the cleareft light of which it will, perhaps, admit in the prefent limited fphere of our knowledge and capacities. He has difplayed, throughout the whole performance, a clearnefs and accuracy of apprehenfion, a depth and folidity of judgment, and a force and acutenefs of reafoning, which give him a juft title to be ranked in the firft clafs of metaphyficians. Mr. Clarke's fecond treatife, on the Evidences of Natural and Revealed Religion, was not more fortunate than the other in efcaping animadverfion and controverfy. The foundation, on which he built his fyftem, was the eternal differences, relations, and fitneffes of things; and as thofe terms frequently recur in his book, they became, in a confiderable degree, fafhionable in the ethical vocabulary of the day. Notwithftanding this, his hypothefis was rejected by many; and it loft much of the authority it had gained on the promulgation of the more fentimental notions of Lord Shaftfbury, afterwards more fyftematically treated by Profeffor Hutchefon, in his "Inquiry into the Original of our Ideas of Beauty and Virtue," in which the principle of diftinct moral inftincts is propofed and fupported. Mr. Clarke's work is, however, as a whole, ineftimably valuable, as containing the moft fatisfactory proofs of the divine origin, authority, and obligation of the chriftian religion. It has had many able defenders, and among others Dr. Price, who was himfelf a hoft.

In the year 1706 Mr. Clarke's patron fucceeded in his wifh to remove him to London, where he thought he would find a wider field of ufefulnefs for the exercife of his great talents; his intereft procured for him the rectory of St. Bennett's, Paul's Wharf, where he continued for fome time to officiate with the higheft reputation. In the courfe of this year he publifhed a letter addreffed to Mr. Dodwell; it was in anfwer to a treatife which that gentleman had recently publifhed to prove, among other things, that the foul was not naturally immortal, but became fo at baptifm. Although Dr. Hoadly, in his memoirs of Clarke, obferves that this letter gave general fatisfaction, it does not appear to have enforced univerfal conviction even at that time; for the philofophical part of the argument, on the materiality of the human foul, was taken up and ably defended by Mr. Collins, and the difpute has been fubfequently revived by feveral writers of ability and reputation. Mr. Clarke publifhed alfo this year an elegant Latin tranflation of fir Ifaac Newton's "Treatife on Optics," which he had undertaken at the folicitation of the author, and was, by this means, inftrumental in diffeminating the light which this great philofopher had thrown upon that fubject, among the learned and inquifitive in other parts of Europe. Newton complimented him for this favour with the fum of one hundred pounds for each of his five children.

The bifhop of Norwich having brought his friend to London, now introduced him at court, and procured for him from queen Anne, the appointment to be one of her majefty's chaplains in ordinary; and the rectory of St. James becoming fhortly after vacant, fhe, at the bifhop's requeft, prefented it to Mr. Clarke. On this elevation to a fituation, where he would be attended by and be obliged to affociate with the higheft characters in the ftate, it was deemed defirable that he fhould take the degree of doctor in divinity. With this view he repaired to Cambridge, where he performed a public exercife which was long remembered, and which, at the time, filled thofe who heard it with aftonifhment and delight, by the erudition it difplayed, and the eloquence and claffical purity of language with which it was compofed and delivered. Mr. Clarke's thefis was an elaborate difquifition on the following queftion; "Nullum Fidei Chriftianæ Dogma, in S. Scripturis traditum, eft rectæ rationi diffentaneum." "No Article of the Chriftian Faith, delivered in the Sacred Scriptures, is contrary to right Reafon;" which he maintained in a moft mafterly manner, againft his acute and learned opponent, Dr. James, the regius profeffor.

In the year 1712, Dr. Clarke appeared in a new character, and difplayed his tafte in philological erudition, by the publication of a moft fplendid edition of Cæfar's Commentaries in folio, enriched with many judicious notes and corrections, and embellifhed with fome beautiful engravings. Mr. Addifon fpeaks, in deferved commendation of this book in the 367th number of the Spectator, as a work that did honour to the Englifh prefs. Since that time it has continued to rife in value, and is now fold at very advanced prices. An octavo edition of it was afterwards publifhed. This year Dr. Clarke involved himfelf in a protracted, and, on many accounts, painful controverfy by the publication of his "Scripture Doctrine of the Trinity." An application was made to him previous to its appearance by fome of the minifters of queen Anne, to defire he would abandon his intentions, or at leaft delay the publication; but he, much to his honour, difregarded their requeft, and boldly fubmitted his opinions to the examination of the public. The method purfued by him in treating fo tender a fubject, was certainly the moft candid and unobjectionable that could well be devifed. The firft part contains a "Collection and Explication of all the Texts in the New Teftament relating to the Doctrine of the Trinity;" in the fecond, "The foregoing Doctrine is fet forth at large, and explained in particular and diftinct Propofitions;" and in the third part, "The principal Paffages in the Liturgy of the Church of England relating to the Doctrine of the Trinity are confidered." Nothing could be more fair than to try a doctrine afferted by its abettors to be exclufively a doctrine of revelation, by the language and expreffions in which that revelation is conveyed, and by a full and critical examination, collectively and feparately, of all the paffages wherein it is fuppofed to be taught. It is impoffible that any method can be more likely to elicit the truth, and to point out to the ferious inquirer what he ought to believe. But notwithftanding Dr. Clarke's candid manner of bringing the fubject forward into difcuffion, it occafioned a controverfy, in which paffion and bigotry had far too large a fhare of influence. Dr. Hoadly remarks, however, that the difpute lay at laft principally between the author and a writer (who was known to be Dr. Waterland), whom he ftyles very fkilful in the management of a debate, and very learned and well verfed in the writings of the ancient fathers. But Dr. Clarke was not to be let off with the fimple warfare of printed controverfy, in which, indeed, he appeared to combat his adverfaries with manifeft fuperiority in point of weapons and fkill. A complaint was formally made to the bifhops by the lower houfe of convocation, in 1714, of the heterodox opinions and dangerous

tendency

tendency of the work in queſtion; and, at the requeſt of the upper houſe, they afterwards delivered in extracts from it in proof of their charges. To theſe extracts Dr. Clarke wrote a reply; but from ſome cauſe or other, not now to be aſcertained, it was not laid before the houſe. The biſhops evinced on this occaſion a very becoming ſpirit of conciliation and peace; and endeavoured to calm the violence which was ſo conſpicuous in the proceedings of their brethren of the lower houſe. Dr. Clarke, we are told, was *prevailed upon* to lay before the upper houſe a paper, which was regarded as his ſubmiſſion, and which certainly tended to convey the impreſſion, that he believed in the doctrine of the trinity in the ſenſe wherein it is commonly underſtood. His declarations are not, indeed, explicit; nor were they admitted by the lower houſe as a ſatisfactory exculpation from their charges; but they were, nevertheleſs, ſuch as it ill became ſo great a man, ſo learned an advocate, and ſo liberal and enlightened a philoſopher, to condeſcend to make. His friend Whiſton, who had a bolder ſpirit, did not ſcruple to cenſure his conduct; and, in juſtice to Dr. Clarke, it muſt be obſerved, that he afterwards condemned it himſelf, and ſaw, but too late, the error he had committed. He drew up a paper in explanation of the former, which was given in to the upper houſe of convocation; but the ſeaſon was paſſed, and his enemies had caught the opportunity to triumph over his failing. On the conſideration of his firſt paper the biſhops, though much to the diſſatisfaction of thoſe who had preferred it, diſmiſſed the complaint. It was ſuppoſed and aſſerted by ſome, particularly by chevalier Ramſay, that Dr. Clarke after this changed his opinions reſpecting the Trinity, and relinquiſhed the ſentiments maintained by him in his "Scripture Doctrine;" but this charge has been diſproved by the ſtrongeſt evidence, and by the moſt reputable and competent authorities,—by Dr. Clarke's own writings and emendations in the liturgy made but a ſhort time previous to his death,—by the teſtimonies of his friend and biographer doctor Hoadly,—and of his own ſon Mr. Samuel Clarke.

In the years 1715, 1716, Dr. Clarke engaged in an amicable controverſy with the learned Leibnitz, on the abſtruſe, metaphyſical doctrines of philoſophical liberty and neceſſity, in which each of theſe able diſputants diſplayed all the ſkill in argumentation and debate, of which they were reſpectively maſters. The papers written on this occaſion were printed in the year 1717, and inſcribed to the princeſs of Wales, afterwards queen Caroline, through whoſe hands they had all paſſed, and whom Dr. Hoadly calls the witneſs and judge of every ſtep of the controverſy. Dr. Clarke, in the year 1718, gave riſe to a curious controverſy reſpecting apoſtolical and primitive doxologies, by introducing ſome alterations into thoſe of the ſinging pſalms which had been that year reprinted for the uſe of his church. The alteration complained of conſiſted in aſcribing glory to God *through* Chriſt, inſtead of paying *equal* honours to each of the three perſons of the Trinity. On this occaſion the biſhop of London thought the ſubject of ſufficient importance to publiſh a paſtoral letter to the clergy of his dioceſe, to warn them againſt innovations, and to forbid them to uſe the new doxologies. This letter was anſwered by Whiſton, and occaſioned the publication of ſeveral pamphlets on both ſides of the queſtion. Whiſton, however, obſerves, that the biſhop of London, in the way of *modern authority*, was quite too hard for Dr. Clarke in the way of primitive Chriſtianity. About this period Dr. Clarke was preſented to the maſterſhip of Whigſton Hoſpital, a poſt which he did not ſcruple to accept, as it did not require him to renew his ſubſcription, and which was rendered doubly agreeable to him by the handſome manner in which it was conferred by Mr. Lechmere, chancellor to the Duchy of Lancaſter. In 1724 he publiſhed ſeventeen ſermons in an octavo volume, eleven of which had never before been printed. On the death of ſir Iſaac Newton, the maſterſhip of the Mint, which by that event became vacant, was offered to him; but being a ſecular preferment, Dr. Clarke, with a very becoming reſpect to the dignity of his character, and agreeably to the opinion of his beſt friends, declined to accept it. In the year 1728, he publiſhed in the Philoſophical Tranſactions (No. 401), a letter addreſſed to Mr. Benj. Hoadly, on the velocity and force of bodies in motion; which is an able vindication of the doctrine of ſir Iſaac Newton on that ſubject.

Dr. Clarke's philological labours, as editor of Cæſar's Commentaries, have already been noticed. In the year 1729, he gave new proofs of his refined taſte and critical ſkill in the learned languages, by the publication of the 12 firſt books of Homer's Iliad, which he accompanied with an elegant Latin verſion, and illuſtrated with a number of very learned and moſt excellent notes and annotations. Homer, we are told, was his favourite author; and he has acted towards him in a manner worthy of his partiality, by ſtripping him of the ambiguities in which ignorance had involved his meaning, and preſenting him to the learned world in his native ſimplicity and beauty. The twelve laſt books were publiſhed in 1732 by Dr. Clarke's ſon; from whom we learn that Dr. Clarke had himſelf finiſhed his annotations on the three firſt of them, and part of the fourth. This work ſtill maintains its well-deſerved reputation, and continues to be received into our principal ſchools.

In the midſt of theſe various labours of public utility, Dr. Clarke was interrupted and cut off in the full maturity and ſtrength of his intellectual powers, by a pleuritic indiſpoſition, by which he was attacked on the 11th of May, 1729, after he had gone to Serjeants' Inn to preach before the judges. It baffled all medical aid, and, after ſubjecting him to very acute ſufferings, proved fatal to him on the 17th of the ſame month. Since his death his brother has publiſhed an "Expoſition of the Church Catechiſm," which compriſed the ſubſtance of a courſe of lectures which Dr. Clarke had delivered on this ſubject while miniſter of St. James's pariſh. He had carefully reviſed them before his death, and left them ready for publication. But his poſthumous publication of greateſt importance is the collection of his ſermons in ten volumes, which were given to the public by the ſame reſpectable relation. As a writer of ſermons, Dr. Clarke had many excellencies. Whatever ſubject he treats, his matter is ſolid and important, his arrangement lucid and comprehenſive, his illuſtrations apt and impreſſive, and his language plain, perſpicuous, nervous and perſuaſive. In his explications of Scripture he is peculiarly happy; for if it be objected to them in any inſtance, that they are more elaborate and circumſtantial than neceſſary, their length will be found to be amply compenſated by their intrinſic excellence and value. Dr. Clarke's character as a writer on all the ſubjects to which he directed his attention, ſtands deſervedly high. His works, although they diſplay no brilliancy of imagination or dazzling coruſcations of genius, are a ſtanding monument of a great and comprehenſive mind, which could bring within its graſp all uſeful and ornamental learning, and treat whatever ſubjects came under its obſervation with equal ability, accuracy, and preciſion. In theology, in metaphyſics, in natural philoſophy, and in claſſical erudition, he has eſtabliſhed a credit which will be as laſting as ſcience itſelf. His penetration was on all occaſions lively and ſtrong, his memory retentive and faithful, and his judgment equally perfect to direct him in the application of its vaſt ſtores.

To

To these high intellectual endowments, Dr. Clarke joined a mild, modest, and unassuming temper, the most amiable and affectionate disposition, sincere and elevated piety, and the most unimpeachable uprightness, and purity of conduct and behaviour.

Hoadly's Account of the Life, &c. of Dr. S. Clarke, prefixed to his works. Whiston's Historical Memoirs of the Life of Dr. Samuel Clarke, 8vo. Biog. Brit.

Clarke, William, an eminent antiquary, was born at Haghmon abbey, in the county of Salop, in 1696. The first part of his education he received at the grammar-school in Shrewsbury; whence he removed to Cambridge, and became a fellow of St. John's, in that university, in January 1716-17. His rising reputation soon procured for him the situation of domestic chaplain to Dr. Ottley, bishop of St. David's; and on that prelate's death, in 1723, he was appointed domestic chaplain to the duke of Newcastle. In this situation he did not continue long; for archbishop Wake, from motives of personal respect, as well as a regard to the solicitation of Dr. Wotton, whose daughter Mr. Clarke had married, presented him to the rectory of Buxted, in Sussex. It is remarkable that Mr. Clarke did not take his bachelor's degree before the year 1731, nor that of master of arts before 1735. In 1738 he was made prebendary and residentiary of the cathedral church of Chichester. Mr. Clarke's first appearance as a writer was in a preface to Dr. Wotton's "Leges Walliæ, or the Ecclesiastical and Civil Laws of Howel Dda, and other Princes of Wales." It has been supposed, that a valuable "Discourse on the Commerce of the Romans," re-printed by the learned Bowyer, with whom he was in the habit of corresponding, in his "Miscellaneous Tracts," came from his pen. But the work on which Mr. Clarke's character as an antiquary is chiefly founded, is that on "The Connection of the Roman, Saxon, and English Coins; deducing the Antiquities, Customs, and Manners of each People to modern Times; particularly the Origin of Feudal Tenures and Parliaments; illustrated throughout with critical and historical Remarks on various Authors, both sacred and profane:" it was published in 1767, in one volume in quarto, and dedicated to the duke of Newcastle. This publication was occasioned principally by the discovery which Mr. Martin Folkes had lately made of the old Saxon pound: it received some improvements from the suggestions of Arthur Onslow, esq., the speaker, and was greatly indebted to Mr. Bowyer for some notes, a dissertation on the Roman sesterce, and a valuable index. The work has been much esteemed by learned men, as elucidating many obscure, but interesting subjects, connected with the history of this country. Mr. Clarke assisted Mr. Bowyer in translating "Trapp's Lectures on Poetry;" and wrote several notes to the English version of "La Bleterie's Life of Julian." Several other writings were left by him in manuscript, particularly some sermons, and some curious papers relating to the history, &c. of the county of Sussex. Although antiquities appear to have engrossed the principal part of his attention, he is said to have possessed a taste for poetry; and some lines of his, published by his friend Mr. Hayley, prove him to have had considerable talent for epigrammatic composition. In 1768 he resigned the rectory of Buxted to his son Mr. Edward Clarke, and in 1770 he was presented to the vicarage of Amport, and appointed chancellor of the diocese of Chichester: but he did not long live to enjoy this promotion, being taken away by death in October 1771. In private life Mr. Clarke was distinguished by the mildness and amiableness of his character, and in his public conduct, by his unremitting attention to his professional duties. His son, Mr. Edward Clarke, above-mentioned, passed some time in Spain, in the capacity of chaplain to the earl of Bristol, the English ambassador; and, on his return, published some "Letters concerning the Spanish Nation," containing much useful information respecting that country. Biog. Brit.

Clarke, Jeremiah, an English organist and ecclesiastical composer, had his education in the Chapel Royal, under Dr. Blow, who seems to have had a paternal affection for him. In 1693 he resigned, in his favour, the place of master of the children and almoner of St. Paul's, of which cathedral Clarke was soon after likewise appointed organist. In 1700 Dr. Blow and his pupil were appointed gentlemen extraordinary in the King's chapel; of which, in 1704, on the death of Mr. Francis Piggot, they were jointly admitted to the place of organist.

The compositions of Clarke are not numerous, as an untimely and melancholy end was put to his existence before his genius had been allowed time to expand.

Early in life he was so unfortunate as to conceive a violent and hopeless passion for a very beautiful lady of a rank far superior to his own; and his sufferings, under these circumstances, became at length so intolerable, that he resolved to terminate them by suicide. The late Mr. Samuel Wiley, one of the lay-vicars of St. Paul's, who was very intimate with him, related the following extraordinary story. "Being at the house of a friend in the country, he found himself so miserable, that he suddenly determined to return to London; his friend observing in his behaviour great marks of dejection, furnished him with a horse, and a servant to attend him. In his way to town, a fit of melancholy and despair having seized him, he alighted, and giving his horse to the servant, went into a field, in the corner of which there was a pond surrounded with trees, which pointed out to his choice two ways of getting rid of life; but not being more inclined to the one than the other, he left it to the determination of chance; and taking a piece of money out of his pocket, and tossing it in the air, determined to abide by its decision; but the money falling on its edge in the clay, seemed to prohibit both these means of destruction. His mind was too much disordered to receive comfort, or take advantage of this delay; he therefore mounted his horse and rode to London, determined to find some other means of getting rid of life. And in July 1707, not many weeks after his return, he shot himself in his own house in St. Paul's church-yard; the late Mr. John Reading, organist of St. Dunstan's church, a scholar of Dr. Blow, and master of Mr. Stanley, intimately acquainted with Clarke, happening to go by the door at the instant the pistol went off, upon entering the house, found his friend and fellow-student in the agonies of death."

The anthems of this pathetic composer, which Dr. Boyce has printed, are not only more natural and pleasing than those of his master Dr. Blow, but wholly free from licentious harmony and breach of rule. He is mild, placid, and seemingly incapable of violence of any kind. In his first anthem (vol. ii.) which required cheerfulness and jubilation, he does not appear in his true character, which is tender and plaintive. The subject of the next is therefore better suited to the natural bias of his genius. There is indeed nothing in this anthem which indicates a master of grand and sublime conceptions; but there are a clearness and accuracy in the score, and melancholy cast of melody and harmony suitable to the words, which are likewise well accented, that cannot fail to soothe and please every appetite for music which is not depraved.

His full anthem, "Praise the Lord, O Jerusalem," is extremely natural and agreeable, and as modern and graceful as the gravity of the choral service will with propriety allow.

And

And in his verse anthem, the movements in triple time are as pathetic, and even elegant, as any music of the same period, ecclesiastical or secular, that was produced, either at home or on the continent. There is a very agreeable verse anthem of his composition in a collection published by Walsh, "The Lord is my strength and my song," with more spirit in it than we thought he could muster. But the verse, "O Lord, send us now prosperity," on a ground-base in Purcell's manner, is extremely pleasing and ingenious. Tenderness is, however, so much his characteristic, that he may well be called the musical Otway of his time.

Clarke, John, an engraver, who resided at Edinburgh, where he engraved the portraits of William Prince of Orange, and the princess Mary, in the form of a medallion; it is dated 1690. Amongst other portaits by him, are those of Sir Matthew Hale and Andrew Marvell; besides which, he engraved two sets of prints, called the Humours of Harlequin and Columbine.

Strutt and Heinecken mention another John Clarke, who lived in England at the same period; and two other engravers, called William and Thomas Clarke. The latter flourished in 1635.

Clarke, in *Geography*, a county of Kentucky, between the head-waters of Kentucky and Licking rivers. Its chief town is Winchester.

Clarke, a town of America, in the state of Virginia, 9 miles N.W. of Richmond.

CLARKSBURG, the chief town of Harrison county, in Virginia; seated on the E. side of Monongahela river, 40 miles S.W. of Morgan-town, and containing about 40 houses, a court-house, and gaol.

CLARKSTOWN, a town of America, in the state of New-York, and county of Orange, lying on the W. side of the Tappan sea, at the distance of 2 miles, and 29 miles from the city of New-York; by the state census of 1796, 224 of its inhabitants are electors.

CLARKSVILLE, the chief town of the district, which, till of late, was called Tennessee county, in the state of Tennessee, in America, pleasantly seated on the E. bank of Cumberland river, and at the mouth of Red river, opposite to that of Muddy creek; containing about 30 houses, a court-house, and a gaol, and distant 45 miles N.W. from Nashville, and 940 W. by S. from Philadelphia. N. lat. 36° 25'. W. long. 88° 57'.

Clarksville, a small settlement of America, in the N.W. territory, which contained in 1791 about 60 persons. It is situated on the northern bank of the Ohio, opposite to Louisville, a mile below the Rapids, and 100 miles S.E. of Port Vincent. It is often flooded when the river is high, and inhabited by people who cannot at present find a better situation.

CLARO-OBSCURO. See Clair-*obscure*.

CLAROS, in *Ancient Geography*, a wood and temple of Apollo in Ionia, in the country of the Colophonians, according to Strabo, who adds, that they were situated before the town of Colophon, and that they were consecrated to Apollo, who had formerly an oracle there.—Also, a town of Asia, in Ionia.—Also, a mountain of Asia Minor, in Ionia, near the town of Colophon. Apollo is supposed by some to have derived from this place his appellation of "Clarian."—Also, an island of the Ægean sea, since called "Calamo," and the "Calymna" of Pliny.

CLARTHY, in *Geography*, a river of Wales in the county of Cardigan, which joins the Clarwen at the N.W. extremity of the county of Brecknock.

CLARWEN, a river of Wales, which runs into the Wye near Rhaiadr-Gwy.

CLARY, in *Botany* and *Gardening*. See Salvia.

Clary, in *Geography*, a town of France, in the department of the north, and chief place of a canton in the district of Cambray; the place contains 1494, and the canton 17,205 inhabitants; the territory includes $132\frac{1}{2}$ kiliometres, and 17 communes.

Clary-*water*, is composed of brandy, sugar, clary-flowers, and cinnamon, with a little ambergris dissolved in it. It helps digestion, and is cardiac. This water is rendered either purgative or emetic, by adding resin of jalap and scammony, or *crocus metallorum*. Some make clary-water of brandy, juice of cherries, strawberries and gooseberries, sugar, cloves, white pepper, and coriander seeds; infused, sugared, and strained.

CLASMIUM, in *Natural History*, the name of a genus of fossils, of the class of the gypsums; the characters of which are, that they are of a soft texture, and of a dull and opake look, being composed, like all the other gypsums, of irregularly arranged flat particles.

The word is derived from κλασμος, *a fragment*, or *small particle*, from the flaky small particles of which these bodies are composed. Of this genus there is only one known species; this is of a tolerably regular and even structure, though very coarse and harsh to the touch. It is common in Italy, and is greatly esteemed there; we have of it also in some parts of Derbyshire; but with us it is not particularly regarded, but burnt among the rest. It neither gives fire with steel, nor ferments with *aqua fortis;* but calcines readily in the fire, and affords a very valuable plaster of Paris.

CLASP-*nails*. See Nails.

CLASPERS, in *Botany*. See Cirrus.

CLASS, *Classis*, a distribution of persons or things, ranged according to their merit, value, or nature. See Rank, &c.

The word comes from *classis*, derived by some from the Greek καλεω, *congrego*, *convoco;* a *class* being nothing but a multitude assembled apart.

Class is particularly used for a distinction among scholars, who are distributed into several classes or forms, according to their capacities and attainments.

Quintilian uses the word *classis* in this sense, in the first book of his "Institutiones."

Class, in *Botany*, a term first employed by Gesner, afterwards taken up by Tournefort, and finally established by Linnæus, to denote the primary division of plants into large groups, each of which is to be subdivided, by a regular downward progression, into orders, or sections, as they are called by Tournefort, genera and species, with occasional intermediate subdivisions, all subordinate to the division which stands immediately above them. So that the classes may be compared to the first layer of a truncated pyramid, which increases gradually as it receives the orders, genera, and occasional intermediate subdivisions, till at length it terminates in an immense base, consisting entirely of species. A class is thus defined by Tournefort in the Isagoge in Rem Herbariam, prefixed to his "Institutiones Rei Herbariæ," p. 51: Classis autem nomine intelligitur congeries generum, quibus nota quædam communis adeo propria est, ut ab omnibus aliis generibus plantarum prorsus differant. "A class is a collection of genera, all possessing some peculiar common character, by which they may be readily distinguished from all other genera." The definition given by Linnæus in his "Philosophia Botanica," p. 100, is more particular. Classis est generum plurium convenientia in partibus, fructificationis secundum principia naturæ et artis. "A class is founded on the agreement of several genera with each other, in the parts of fructification, according to the principles of nature

nature and art." Tournefort, following the fteps of Gefner, had before determined, though he did not include it in his definition, that the divifion into claffes ought to depend, either folely on the flower, or folely on the fruit; at the fame time affigning the reafon why, in his own practice, he gave the preference to the former. Ifag. p. 65, 66. In the formation of claffes, it is of effential importance that they fhould not be very numerous, and that their boundaries fhould be ftrongly and diftinctly marked. See CLASSIFICATION.

CLASSENDORF, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 5 miles N. of Kamnitz.

CLASSIC, CLASSICAL, a term chiefly applied to authors read in the claffes at fchools, and who are in great authority there. In this fenfe, Aquinas, and the mafter of the fentences, were claffic authors in the fchool-divinity; Ariftotle, in philofophy; Cicero and Virgil, in the humanities. Aulus Gellius ranks among claffic authors, Cicero, Cæfar, Salluft, Virgil, Horace, &c.

The term claffic feems properly applicable only to authors who lived in the time of the Roman republic, and the Auguftan age, when the Latin was in its perfection.

It appears to have taken its rife hence, that an eftimate of every perfon's eftate being appointed by Servius Tullius, he divided the Roman people into fix bands, which he called *claffes*. The eftate of thofe of the firft *claffis* was not to be under two hundred pounds: and thefe, by way of eminence, were called *claffics, claffici*.

Hence, alfo, authors of the firft rank came to be called *claffics:* all the reft were faid to be *infra claffem*.

The firft *claffis*, again, was fubdivided into centuries; making fourfcore centuries of footmen, and eighteen of horfemen. Each *claffis* confifted, one half of the younger fort, who were to make war abroad; and the other of old men, who ftaid at home for the defence of the city.

CLASSICA COLONIA, in *Ancient Geography*, one of the names of a town in Gallia Narbonnenfis, called by Cæfar *Forum Julii*.

CLASSICAL *Learning* may be underftood to fignify fuch an acquaintance with the beft Latin and Greek writers, as fhall enable the reader to perceive and admire the peculiar beauty of their compofitions, and to adopt their diction and fentiment. The principal claffic Greek authors are, Homer, Hefiod, Plato, Demofthenes, Æfchines, Xenophon, Plutarch, Ifocrates, Epictetus, Lucian, Sophocles, Euripides, Longinus, Theocritus, Anacreon, Pindar, Ariftophanes, &c. The chief Latin writers are, Cicero, Livy, Cæfar, Salluft, Virgil, Horace, Terence, Plautus, Juvenal, Ovid, Pliny, Valerius Paterculus, Tacitus, &c.

CLASSICUM, in *Ancient Military Language*, the found of a trumpet, or a trumpet itfelf. When the Romans wifhed to give the fignal for combat, one man by order, and in prefence of the general, founded with the trumpet. Several others, on an elevated fituation, if there was one near them, anfwered the fignal with the found of their trumpets; and at this fecond fignal, the trumpets of all the cohorts founded at once.

CLASSIFICATION, in a general fenfe, denotes the arrangement or affortment of various objects into thofe feveral claffes, denoted by appellatives, which, in the fchools, are called *genera* and *fpecies*. It is, fays the ingenious Dr. Smith, (Differtation on the Origin of Languages, annexed to his Theory of Moral Sentiments), an application of the name of an individual to a great number of objects, whofe refemblance naturally recals the idea of that individual, and of the name which expreffes it, that feems originally to have given occafion to the formation of thofe claffes and affortments, which, in the fchools, are called *genera* and *fpecies*; and for the origin of which Rouffeau finds himfelf fo much at a lofs to account. What conftitutes a *fpecies* is merely a number of objects, bearing a certain degree of refemblance to one another; and, on that account, denominated by a fingle appellation, which may be applied to exprefs any one of them.

This claffification of different objects, as profeffor Dugald Stewart accurately and fatisfactorily ftates it, (Elements of the Philofophy of the Human Mind, p. 155, &c.) fuppofes a power of attending to fome of their qualities or attributes without attending to the reft; for no two objects are to be found without fome fpecific difference; and no affortment or arrangement can be formed among things not perfectly alike, but by lofing fight of their diftinguifhing peculiarities, and limiting the attention to thofe attributes which belong to them in common. This power of confidering certain qualities or attributes of an object apart from the reft; or the power, as the ingenious profeffor chufes to define it, which the underftanding has of feparating the combinations which are prefented to it, is diftinguifhed by logicians by the name of "abftraction," which fee. Abftraction, which fome philofophers have fuppofed to form the characteriftical attribute of a rational nature, is the ground-work of claffification; and without this faculty of the mind we fhould have been perfectly incapable of general fpeculation, and all our knowledge muft have been limited to individuals; while fome of the moft ufeful branches of fcience, particularly the different branches of mathematics, in which the very fubjects of our reafoning are abftractions of the underftanding, could never have poffibly had an exiftence.

CLASSIFICATION *of Animals for Comparative Anatomy*. The firft fyftematic arrangements of animals were founded upon their external figure and moft obvious habits of life; confequently they were always imperfect, and often erroneous; thus, the divifion of animals into terreftrial, aërial, and aquatic, although apparently natural, included, under the fame title, individuals no way allied to each other, except in the form of their bodies, and the element they inhabited: it is in this manner that the vulgar determine the rank of animals at prefent; thus, the whale tribe, and even feals, are called fifhes, and many mollufca and other marine animals are very generally termed fifh.

In proportion to the cultivation and advancement of the ftudy of zoology, it became neceffary to inftitute claffes and orders founded upon lefs obvious characters than the general appearance or economy of the animals; for which purpofe, the number and arrangement of the toes, teeth, claws, beaks, fcales, and other obfcure or minute parts were employed; and by thefe means the primary divifions and fubdivifions of the animal kingdom were made more numerous; the tranfition from them to the genera lefs abrupt; and the difcrimination of fpecies more eafy and accurate.

It was on this plan that Linnæus proceeded in the formation of his great fyftem, which has been fo much and fo generally admired; the characters he chofe, however, were confeffedly artificial; and as his objects chiefly feemed to be the afcertainment and defcription of the fpecies, he often difregarded natural order, and frequently violated it in the moft palpable manner: his diftinctions are more efpecially at variance with the anatomical ftructure of animals; even where he propofed to form his fyftem upon this foundation, he frequently fell into error.

In order to juftify our departure from a fyftem which the naturalifts of this country have not yet rejected, it will be be necessary to point out some of its more objectionable parts. Linnæus makes two grand divisions of animals, the *red* and the *white-blooded;* and under the latter denomination, he includes many animals in whom no blood or circulating fluid exists, and some others whose blood is really red. The class of *vermes*, which most people would expect to signify worms, contains all the inferior orders of animals, except insects; thus assembling together genera having as little alliance to each other, with respect to form, habits, and organization, as there exists between a quadruped and a fish. For example, what resemblance is there between a cuttle fish, an earth-worm, and a hydatid? or how can the common attributes of worms, *viz.* an unilocular heart and cold white blood be applied to them? The cuttle-fish has three hearts, placed at some distance from each other; its blood is transparent; the male and female organs of generation exist in separate individuals; the animal is furnished with numerous external organs, and possesses the senses of vision and hearing, and resides in the sea. The earth-worm has no heart; its blood is red; has both male and female organs in the same individual; can scarcely be said to possess any projecting external parts; is destitute of the senses of sight and hearing, and is an inhabitant of the earth.

Lastly, the hydatid has neither blood nor circulating vessels; is without sex; is unprovided with any organs of sense or of motion, and lives in the interior of other animals.

The constitution of the Linnæan orders is not more natural than that of the classes. One of the most remarkable examples of artificial arrangement presents itself in the first order of mammalia; in which we find man and the bat associated together; two animals, between whom there is no circumstance of agreement, except the situation of their mammæ, which Linnæus makes an essential character of the order.

The animal, to which man bears the greatest resemblance with respect to external form, is the monkey; but from which he is so distinguished by his mode of progression, that he should be placed, even on that account, in a separate order, if not in a distinct class.

The position of the head, by which it is equipoised upon the vertebral column, the forward direction of the eyes, the want of a cervical ligament to assist the muscles of the neck in sustaining the weight of the head, the capacity of the chest, which would interfere with the employment of the superior extremities, as feet, the shape of the pelvis, and of the cavity for receiving the head of the thigh bone, the length of the inferior extremities, the strength of the posterior muscles of the leg, and the projection of the heel, which increases their power, the position of the sole of the foot, the conjunction of the great toe with the others, and the original thickness of the integuments of the bottom of the feet, are all peculiarities of the human body; and concur to prove that man was designed by nature to walk erect, whilst the structure of the most perfectly formed monkey prevents the animal's sustaining the upright position for any length of time without an effort, or without clinging to some external support.

The mental character, the instincts, and the habits of the human kind, are, however, so very peculiar, and so very important in their consequences, that in all systems of natural arrangement, man ought to constitute a class distinct from all other animals. Man alone is endowed with the faculty of reasoning and a moral sentiment; for in those instances where animals have appeared to act from judgment, it was the result of imitation, instinct, or a previous education. Human language is almost always artificial, and formed by convention, and may be used as the signs of abstract ideas; whilst that of animals consists of instinctive cries or sounds, which commonly express only immediate wants or sensations. No animal is capable of constructing tools or machinery for the purpose of diminishing labour; whilst mankind perform almost all their actions with the aid of instruments or machines. The mechanical powers of the human race have a most extensive influence upon its natural history: it is by these that man is able to maintain his dominion over the rest of the creation, for no animal is naturally so defenceless. Born without weapons, and even any covering, he would be incapable of resisting the attacks of rapacious animals, or of sustaining the extreme effects of climate; it is also by mechanical means that we are enabled to profit by our own or others' experience, and to transmit the inventions and discoveries of one generation to another, which forms one of the most distinguishing characteristics of mankind, and to which they chiefly owe their superiority over the brute creation. The social habits and sexual instincts of the human species are very different from those of animals; almost all the works of man are produced by co-operation, and subordination amongst the agents; but animals commonly act independently, and without controul; for even where their instincts lead them to conduct their labours in concert, every individual performs its own task, without receiving any instructions or commands from others. To live in a state of organized society is, therefore, only natural, and peculiar to the human kind.

In animals the desires of the sexes occur at determined seasons, at which times they are ungovernable, and to their gratification commonly succeeds a sentiment of aversion; whilst the intercourse of the sexes in the human species is not the effect of a periodic instinct, and is always regulated by taste, or some other mental sentiment or consideration, not immediately concerned in the performance of the procreative act.

Many other circumstances might be enumerated, as distinguishing attributes of the human kind, but the above have been adduced as being more peculiarly classific characters, or more properly belonging to natural history; and are sufficient in themselves to shew the impropriety of arranging man with other animals.

In some other Linnæan orders of mammalia, several of the genera have no natural alliance to each other. Thus, in the order *bruta*, we meet with the elephant, the walrus, the sloth, and the anteaters, animals extremely different in their form, organization, and all their habitudes. The order *feræ* includes, with the real beasts of prey, the seal, whose mode of life is so peculiar, and the hedge-hog, mole, and shrew, which are really fugitive animals; and in the order *belluæ* we find the hippopotamus, hog, and tapir, whose uncouth figure, slow, heavy gait, and general economy, plainly declare their relation to the elephant and rhinoceros, with whom they should have been united, rather than with such a fleet and finely proportioned quadruped as the horse.

Although the orders which Linnæus instituted in birds are more natural than those of mammalia, they are not unexceptionable. The genus *lanius* perhaps more properly belongs to the *passerine* tribe, than to the birds of prey. The order *picæ* is unquestionably too extensive, and contains many genera, which, in their general form and modes of life, ought to be placed amongst the passeres. All the orders of birds seem to require a further division; and the peculiarities in the structure and mode of progression in the struthious birds would point out the propriety of forming them into a distinct order. The appellations also of all the orders may be thought to admit of improvement; but

 where

where names do not lead to errors, with refpect to fact, it is of little confeqence whether they be quite appropriate or not.

The orders of the claffes, amphibia and fifhes, as they appear in the later editions of the Syftema Naturæ, are lefs objectionable than any other part of the Linnæan claffification, and, confequently, have undergone lefs alterations by modern naturalifts.

It is in the arrangement of the inferior orders of animals that Linnæus appears to have been moft cenfurable. The order of *apterous infects* is compofed of genera differing fo much from each other in anatomical ftructure, that they have given rife to the formation of fome new claffes by late naturalifts. The orders *mollufca* and *teftacea*, of the clafs *vermes*, are by far the worft conceived parts of the Linnæan fyftem: under the denomination of *mollufca*, we find fome animals that have all the external characters, as well as anatomical ftructure, of *worms*, properly fo called; others, which have fo many peculiarities of form and of organization, that they almoft deferve to conftitute a diftinct clafs; and others again, which are fo fimple in their formation, that they might be confidered as the link between the animal and the vegetable kingdoms. The feparation of the teftaceous from the naked mollufca is a glaring impropriety, unlefs the objects of natural hiftory were merely to defcribe the coverings or habitations of animals, without regard to the real form, ftructure, and habits of the individuals they contain.

The number of the genera and fpecies of animals in every clafs is infinitely increafed fince the days of Linnæus, which is partly the confequence of modern difcoveries, and partly owing to a more accurate examination and comparifon of the fpecies which were already known.

At the fame time that we have thus ventured to cenfure, without referve, the errors of Linnæus, we cannot forbear acknowledging with admiration the talents, zeal, and induftry which he exerted in the fervice of natural hiftory; he has not been furpaffed by any, as a patient and laborious collector of facts, and few have fhewn more ability in the arrangement of their materials. Had he but paid as much attention to natural order, and the anatomy of animals, as he did to artificial characters, his fyftem would have remained a lafting monument of his indefatigable induftry, and comprehenfive genius; and it would have been only left to fucceeding naturalifts to fill up his orders with fuch genera and fpecies as later difcoveries might afford.

It is from accurate and enlarged views of the organization of animals that almoft all the modern improvements with refpect to the claffification of animals have arifen; we cannot wonder, therefore, that we receive them almoft entirely from the naturalifts of France and Germany, who ftudy comparative anatomy with a degree of zeal and attention unknown in this country.

Of thofe who have contributed to the introduction of a natural method in zoology, we may enumerate Daubenton, Vic d'azir, Blumenbach, Fabricius, Geoffroy, Cuvier, Brongniard, La Cepede, La Marck, Latreille, Dumeril, &c.

In compofing the following claffification of animals we have made a free ufe of the works of the above writers, not however, by fervilely copying them, but by adopting their arrangement wherever we confidered it juft and natural. In fome inftances, when we thought it neceffary, we have ventured to differ decidedly even from fuch celebrated authorities, and in other cafes we have added fuch new divifions of animals, as appeared to be required, more efpecially for the convenience of anatomical defcription. The claffification of mammalia is nearly the fame as that propofed by Geoffroy and Cuvier; we have, however, given different names to feveral of the families, and have feparated the genus Lamantin from the feal and whale tribes, as differing from both in form and in anatomical ftructure. The clafs of birds is formed upon the plan of that contained in Cuvier's Tableau Elementaire de l'Hiftoire naturelle, except that we have made a diftinct order of the running birds, and have tranfpofed fome of the other genera. In the arrangement of reptiles we have followed that of Brongniard and Daudin, with the inftitution of the additional family of amphibia, including the firens which we have judged it proper to feparate from the frog kind, until it be determined whether they are animals in a tadpole ftate of exiftence or not. In the clafs of fifhes we have adopted the fyftem of La Cepede, as lately modified by Dumeril, in which are introduced the genera of Bloch, La Cepede, Commerfon, &c. In the conftitution of the mollufca, the lateft improvements of Cuvier have been admitted, who was the author of the clafs, and to thefe we have added fome other fubdivifions, which appeared to be both natural and confonant. The arrangement of winged infects is the fame which Dumeril has formed from the Linnæan and Fabrician fyftems, but we have replaced the two genera cancer and monoculus of Linnæus amongft the apterous infects, although all the French naturalifts had agreed that they fhould conftitute a diftinct clafs to which they gave the name of cruftacea. The eftablifhment of the clafs cruftacea does not appear to reft upon good principles. It was inftituted upon the grounds of the animal compofing it having divided blood veffels, and the prefumption of there being no vafcular fyftem in the other families of infects. There would feem, however, to be a regular gradation from the heart and large arteries of cruftacea to the dorfal veffel of flying infects. In fome that hold an intermediate place, fuch, for example, as fpiders, ramifications of the dorfal veffel can be detected; and analogy would lead us to conclude that the dorfal veffel of flying infects performs at leaft fome of the functions of the heart and principal arteries of cruftacea, and that the large veins of the latter may be fo much extended as at laft to occupy the entire cavity of the body of the infect, and thus elude our obfervation. But granting the opinion of the French naturalifts to be correct, (which is not probable) that infects have no apparatus for preparing the nutritious fluid previous to its converfion into the organic ftructure of the animal, ftill there are fo many circumftances of refemblance between cruftaceous and other infects, that they cannot with propriety be placed in feparate claffes; they have both the external fkeleton, both poffefs a fimilar ftructure of the mufcles and the fame arrangement of the nerves, they are alike furnifhed with antennæ and compound eyes, which exift in no other clafs of animals. The lateral pofition of the jaws, and the want of glandular vifcera, which are fupplied by numerous tubes connected with the alimentary canal, are alfo peculiarities of ftructure only found in cruftaceous and other infects. After fully confidering all the characters of the cruftacea of Cuvier we have judged it beft to form thefe animals into two orders of apterous infects, one of which is the true cruftacea and correfpond to the genus cancer (Linn.) and the other is the genus monoculus (Linn.) or the teftaceous infects of Muller. We have alfo inftituted fome other natural families of apterous infects, one of which nearly anfwers to the *arachnides*, a clafs lately formed by fome of the French naturalifts upon ftill lefs pretence than that of cruftacea.

The divifion of worms into thofe refiding in the earth or water, and thofe inhabiting the interior of other animals, is fo very obvious that it has been made by moft naturalifts; but La Marck and Dumeril have gone farther, and have ranked inteſtinal worms amongſt zoophytes, which the ſimplicity of their organization might perhaps authoriſe; but on account of their uſual form and affinity which ſome of the ſpecies bear to the external worms, we have been induced to ſtill retain them in the claſs of vermes.

The claſs of zoophytes is formed upon the plan generally adopted by the French naturaliſts: we have, however, made ſome more ſubdiviſions, eſpecially of the zoactinia, or radiated animals.

It is not expected that the annexed claſſification will meet univerſal approbation from Engliſh readers; ſome entertain ſo high a reverence for every thing belonging to Linnæus, that they will not hear of the leaſt deviation from his ſyſtem; not remembering that the nature of truth and error is the ſame, whether it be ſanctioned by authority or not. Others may object to the introduction of ſo many ſubdiviſions of the claſſes, and the employment of new terms, from an apprehenſion that they will increaſe the difficulties (already too numerous) attending the ſtudy of natural hiſtory. To theſe it may be obſerved that the acquiſition of every ſpecies of knowledge is facilitated by judicious ſubdiviſions and appropriate terms, and that all the obſcurity and confuſion of natural hiſtory have ariſen from the want of a proper nomenclature. It has been long known that the ſpecies are eaſily diſcovered after we are acquainted with the characters of the genus to which they belong, and that the moſt difficult part, both of zoology and botany, is to attain a knowledge of the genera; the obvious reaſons for which are, that the paſſage from the genera to the ſpecies is ſhort and eaſy, while the former are too much eſtabliſhed upon independent characters, and are not the branches of the orders, or the ſubdiviſion next above them. The inſtitution of ſub-orders is eminently calculated to remove theſe difficulties; and if they be conſtructed ſo as to form natural families, they greatly facilitate and extend our acquaintance with the habits, manners, and economy of animals, which are the true objects of natural hiſtory.

To fully perceive the utility of ſub-diviſions and general terms in zoology, we ſhould ſuppoſe the ſubject in its two extremes; one when all the names are individual, or at moſt ſpecific; the other where there are regular and natural gradations from the claſs to the ſpecies; in the firſt caſe the ſtrongeſt memory would hardly embrace the number of individuals contained in one genus, while, in the other, the whole animal kingdom might be ſurveyed with eaſe; but it is needleſs to dwell upon the convenience and neceſſity of arrangement in a ſcience which eſſentially conſiſts in the generalization and compariſon of facts.

The improvements in the claſſification of the ſubjects of natural hiſtory, like the new chemical nomenclature, have been treated in this country with contempt and deriſion, and like it, alſo, they will be ſlowly, yet univerſally acknowledged. One reaſon alone, if there exiſted no other, would juſtify our adoption of the modern ſyſtem of claſſification, upon the preſent occaſion: it is becauſe it is the moſt conſonant with the anatomical ſtructure of animals, which we have to deſcribe, and in reference to which, alone, the following tables are conſtructed.

VIEW of the CLASSES of ANIMALS.

					Classes.
ANIMALS.	A brain containing cavities; an internal oſſeous ſkeleton	warm blood, and heart with two ventricles	viviparous, and ſuckle their young	I.	MAMMALIA.
			oviparous, and without mammæ	II.	AVES.
		cold blood, and heart with one ventricle	having lungs, and wanting fins .	III.	REPTILIA.
			with gills and fins	IV.	PISCES.
	Without a brain or internal ſkeleton	An articulated external ſkeleton		V.	INSECTA.
		No articulated members	Simple nerves	VI.	MOLLUSCA.
			Knotted nerves	VII.	VERMES.
			Without nerves	VIII.	ZOOPHYTA.

CLASS I. MAMMALIA.

		Orders.
The Feet	divided into digiti or toes, which are furniſhed with claws or nails	1. Digitata.
	having the parts correſponding to the toes enveloped in horny caſes or hoofs	2. Ungulata.
	degenerated into the form of fins, and employed for ſwimming	3. Pinnata.

CLASSIFICATION.

DIGITATA.—First Order of MAMMALIA.

Teeth	Members	Thumb or pollex	Families	Genera		Sub-genera	
of three sorts; members	distinct; the thumb or pollex	separate on both hands and feet	QUADRUMANA	Simia	Ape	Pithecus	Orang.
						Callitrix	Sapajou.
						Cercopithecus	Guenon.
						Cynocephalus	Macaque.
						Papio	Baboon.
						Cebus	Alouate.
				Lemur	Maki	Lemur	Maki or Maucauco
						Indri	Indri.
						Lori	Lori.
						Galago	Galago.
						Tarsius	Tarsier.
		separate on the feet only	PEDIMANA	Uomlatus	Womlat.		
				Didelphis	Opossum	Didelphis	Sarigue.
						Dasyurus	Dasyure.
						Phalangista	Phalanger.
						Coescoes.	
				Perameles	Peramele.		
		not separate; walk on the toes	DIGITIGRADA	Mustela.	Weazel	Mustela	Weazle and Martin
						Lutra	Otter.
						Mephitis	Mouffete.
				Viverra	Civet.		
				Felis.	Cat.		
				Canis	Dog	Canis	Dog.
						Hyæna	Hyæna.
		not separate; walk on the sole of the feet	PLANTIGRADA	Erinaceus	Hedge Hog	Erinaceus	Hedge Hog.
						Setiger	Tenrec.
				Sorex	Shrew	Sorex	Shrewmouse.
						Mygale	Desman or Musk Shrew.
						Chrysochloris	Chrysochlore.
						Scalops	Scalope.
				Talpa	Mole.

						Taxus	Badger.
						Nasua	Coati.
						Procyon	Racoon.
						Potos	Kinkajou.
						Ichneumon	Mangouste.
	united by a membrane in form of a wing		CHEIROPTERA	Vespertilio	Bat	Pteropus	Rousset.
						Vespertilio	Common Bat.
						Rinolophus	Rinolphus.
						Phyllostoma	Phyllostome.
						Noctilio	Noctilio.
				Galeopithecus	Flying Lemur.		
				Phascolomys	Phascolome.		
less than three sorts; want	the canine only; a leaping gait		SALTIGRADA	Kangurus	Kanguroo.		
				Hystrix.	Porcupine	Hystrix	Porcupine.
						Coendus	Coendu
				Lepus	Hare	Lepus	Hare.
						Lagomys	Pica.
				Cavia	Cavy	Hydrochærus.	
						Cavia	Agouti.
				Castor	Beaver.		
				Hydromys.			
				Sciurus	Squirrel	Pteromys	Polatouche, or Flying Squirrel.
						Sciurus	Squirrel.
				Cheiromys	Aye-Aye, or Madagascar Squirrel.		
				Mus	Rat	Arctomys	Marmot.
						Lemmus	Campagnol.
						Fiber	Ondatra.
						Mus	Rat.
						Cricetus	Hamster.
						Spalax	Mole Rat.
						Dipus	Jerboa.
						Myoxus	Dormouse.
	the incisors and canine		EDENTATA	Ornitherincus	Duckbill.		
				Myrmecophaga	Ant-eater	Myrmecophag	Ant-eater.
						Echidna	Porcupine Ant-eater
						Manis	Pangolin or Scaly Lizard.
				Orycteropus	Cape Ant-eater.		
				Dasypus	Armadillo.		
	the incisors only; slow motion		TARDIGRADA	Bradypus	Sloth	Megatherium	Megather.

UNGU-

CLASSIFICATION.

UNGULATA.—Second Order of MAMMALIA.

		FAMILIES.	GENERA.		SUB-GENERA.	
Hoofs	three at least	MULTUNGULATA	Elephas	*Elephant.*		
			Tapir	*Tapir.*		
			Sus	*Hog.*		
			Hippopotamus	*River Horse.*		
			Hyrax	*Daman*		
			Rhinoceros	*Rhinoceros*		
	two; the foot appearing as if cleft in two parts	BISULCA	Camelus	*Camel.*	Camelus	*Camel.*
					Lama	*Peruvian Camel.*
			Moschus	*Chevrotin, or Musk.*		
			Cervus	*Deer.*		
			Camelo-Pardalis	*Giraffe.*		
			Antilope.			
			Capra	*Goat.*		
			Ovis	*Sheep.*		
			Bos	*Ox.*		
	one only; the foot appearing solid	SOLIPEDA	Equus	*Horse.*		

PINNATA.—Third Order of MAMMALIA.

		FAMILIES.	GENERA.	
Posterior feet	with the toes united and turned backwards for swimming	NECTOPODA	Phoca	*Seal.*
			Trichechus	*Morse.*
	concealed in the tail	CRYPTOPODA	Manatus	*Lamantin.*
	completely obliterated, giving the animal the appearance of a fish	CETACEA	Balæna	*Whale.*
			Balenoptera	*Finned Whale.*
			Narwhalus	*Narwal.*
			Anarnacus	*Anarnak.*
			Catodon	*Cachelot.*
			Physalus	*Physalus.*
			Physeterus	*Physeter*
			Delphinus	*Dolphin.*
			Delphinapterus.	
			Hyperoodon	*Grampus.*

CLASS II. AVES.

Number of posterior toes (ORDERS.)

- two, and two anterior toes; tarsus short, and the limbs altogether constructed for climbing. — 4. SCANSORIÆ.
- one, or none; the anterior
  - entirely free; bill and claws strong and sharp; legs very muscular, and fitted for grasping. — 7. ACCIPITRINÆ.
  - united
    - entirely by broad membranes; legs short, and placed backwards, and adapted for swimming. — 6. ANSERINÆ.
    - partially,
      - all at their base; tarsus
        - moderately long and strong. — 2. GALLINACEÆ.
        - long; leg very strong, and fitted for running — 1. CURSORIÆ.
      - the two external; tarsus
        - very long, and calculated for wading — 5. GRALLATORIÆ.
        - moderately long, and slender — 3. PASSERINÆ.

CURSORIÆ.—First Order of BIRDS.

		FAMILIES.	GENERA.	
Number of anterior toes	two	DIDACTYLÆ	Struthio	*Ostrich.*
	three	TRIDACTYLÆ	Rhea	*Tougou.*

					Strix	*Common Owl.*
					Surnia	*Surnia.*

CLASS III. REPTILIA.

			Orders.
Heart	with two auricles; jaws	of horn: without teeth; a back ſhell	1. Chelonia.
		with teeth; no back ſhell	2. Sauria.
	with one auricle; body	without feet; often covered with ſcales	3. Ophidia.
		naked with two or four feet	4. Batrachia.

CHELONIA.—Firſt Order of Reptiles.

		Families.	Genera.	
The Feet	palmated	Marina	Chelonia	*Turtle.*
		Hurcatilia	Emys	
			Chelus	*Matamata.*
	with claws	Terrestria	Teſtudo	*Tortoiſe.*

SAURIA.—Second Order of Reptiles.

		Families.	Genera.	
Tail moſt commonly very long,	flattened ſuperiorly, or upon the ſide	Planicaudata	Crocodilus	*Crocodile.*
			Dracæna.	
			Tupenamlus.	
			Uroplatus.	
			Lophyrus.	
			Baſiliſcus	*Baſiliſk.*
	conic, round	Tereticaudata	Iguana	*Iguana.*
			Draco	*Dragon.*
			Agama.	
			Chamæleon	*Chameleon.*
			Gecko.	
			Stellio.	
			Analis.	
			Lacerta	*Lizard.*
			Scincus.	
			Ahalcides.	
			Seps.	

OPHIDIA.—Third Order of Reptiles.

		Families.	Genera.	
Skin	naked, or equally covered with ſcales under the belly and the tail	Homodermata .	Cæcilia.	
			Amphiſbæna.	
			Acrochordus.	
			Ophiſaurus.	
			Anguis . .	*Snake.*
	with ſcales above; plates under the belly and under the tail	Heterodermata	Hydrophis .	*Water-ſerpent.*
			Platurus.	
			Crotalus.	
			Scytale.	
			Vipera . .	*Viper*
			Coluber.	
			Boa.	
			Erpeton.	
			Erix.	

BATRACHIA.—Fourth Order of Reptiles.

			Families.	Genera.	
Body	ſhort and thick, without tail; anterior feet ſhort; both lungs and gills in the young ſtate		Anoura . .	Pipa.	
				Bufo . . .	*Toad.*
				Rana . . .	*Frog.*
				Hyla . . .	*Tree Frog.*
	elongated; with a tail; feet equal in length; both lungs and gills	in the young ſtate	Deloura .	Triton.	
				Salamandra.	
		during life	Amphibia .	Proteus.	
				Siren.	

CLASS IV. PISCES.

	Sub-classes.				Orders.
Body	with cartilaginous ſkeleton	CARTILAGINEI. Gills	with gill covers, and	with membrane; the gills being complete.	4. Teleobranchiati.
				without membrane; gill covers being free	3. Eleutheropomati.
			without gill covers, and	with membrane; reſpiring through a fiſſure	2. Chismopnes.
				without membrane; reſpiring through holes	1. Trematopnes.
	with oſſeous ſkeleton	OSSEI. Gills	with gill covers, and	with membrane; the gills being entire, or containing all their parts	5. Holobranchiati.
				without membrane; plicated breaſt	6. Sternoptyges.
			without gill covers, and	with membrane; gills concealed	7. Cryptobranchiati.
				without membrane; form of the animal between that of a ſerpent and a fiſh	8. Ophichthoides.

TREMA.

CLASSIFICATION.

TREMATOPNES.—First Order of Fishes.

Ventral fins	Families.	Genera.	
none; mouth round and at the end of the snout	Cyclostomati	Petromyzon	*Lamprey.*
		Gastrobranchus	*Myxine.*
very distinct; mouth wide and transverse	Plagiostomati	Torpedo	*Torpedo.*
		Raia	*Ray.*
		Rhinobatus.	
		Squatinus	*Angel.*
		Squalus	*Shark.*
		Aodon.	

CHISMOPNES.—Second Order of Fishes.

The posterior pair of fins under	Genera.	
the gullet	Batrachus	*Frog-fish.*
	Lophius	*Angler.*
the pectoral fins	Balistes	*File-fish.*
on the belly, behind the pectoral	Chimæra	*Sea monster.*

ELEUTHEROPOMATI.—Third Order of Fishes.

Body		Genera.	
protected by a mailed covering; mouth	without cirrhi	Pegasus	*Pegasus.*
	with cirrhi	Acipenser	*Sturgeon.*
naked and unprotected; snout as long as the body		Spatularia	*Spatula-fish.*

TELEOBRANCHIATI.—Fourth Order of Fishes.

Posterior pair of fins		Families.	Genera.	
distinct	under the pectoral; mouth elongated like a sucker	Aphyostomati	Macrorhyncus	*Macrorhyncus.*
			Centriscus	*Bellows-fish.*
	behind the pectoral-ventral fins veined	Plecopteri	Cyclopterus	*Sucker.*
			Lepidogasterus	*Lepidogasterus.*
wanting; skin covered with a coat of armour or with osseous grains		Osteodermati	Ostracion	*Trunk-fish*
			Tetraodon	*Tetraodon.*
			Diodon	*Porcupine-fish.*
			Spheroides	*Spheroides.*
			Orcides	*Orcides.*
			Cephalus	*Sun-fish.*
			Sygnathus	*Pipe-fish.*

HOLOBRANCHIATI.—Fifth Order of Fishes.

The inferior or ventral pair of fins		Sub-orders.
wanting		1. Apodes.
distinct, under	the gullet	2. Jugulares.
	the pectoral fins	3. Thoracici.
	the belly	4. Abdominales.

CLASSIFICATION.

APODES.—First Sub-order of Osseous Fishes with perfect branchiæ.

		Families.	Genera.	
The other fins beſides the ventral	all exiſt	Peropteri	Cæcilia	*Blind Eel.*
			Monopterus.	
			Leptocephalus	*Morris.*
			Aſtroblepus	*Aſtrobleps.*
			Gymnotus	*Gymnote.*
			Trichiurus	*Trichiure.*
			Trichomycterus.	
			Notopterus.	
			Ophiſurus.	
			Apteronotus.	
	altogether, or partly wanting	Pantopteri	Muræna	*Eel.*
			Ammodytes	*Land Eel.*
			Ophidium.	
			Xiphias	*Sword Fiſh.*
			Anarhichas	*Wolf Fiſh.*
			Comephorus.	
			Stromatæus.	
			Rhombus.	
			Triurus	*Triple Tail.*
			Odontognathus.	
			Macrognathus.	

JUGULARES.—Second Sub-order of Osseous Fishes with perfect branchiæ.

			Genera.	
Body	elongated; apertures of the gills	upon the neck; head thicker than the body	Callionymus	[illegible]
		lateral	Calliomorus.	
			Murenoides.	
			Uranoſcopus	*Stargazer.*
			Trachinus	*Dragenet.*
			Gadus	*Cod.*
			Batrachoides.	
			Blennius	*Blenny.*
			Oligopodus.	
	oval, compreſſed		Kurtus	*Hunchback.*
			Chr[illegible]mus.	

THORACICI.—Third Sub-order of Osseous Fishes with perfect branchiæ.

			Families.	Genera.	
Body very thin	more high than long; eyes	on each ſide	Leptosomati	Chætodon	*Chætodon.*
				Acanthinion	*Acanthinion.*
				Chetodipterus	*Chetodipterus.*
				Pomacentrus	*Pomacentrus.*
				Pomadaſys	*Pomadaſys*
				Pomacanthus	*Pomacanthus.*
				Holacanthus	*Holacanthus.*
				Enopleſus	*Enopleſus.*
				Glyphiſodon	*Glyphiſodon.*
				Acanthurus	*Acanthurus.*
				Aſpiſurus	*Aſpiſurus.*
				Acanthapodus	*Acanthapodus*
				Selene	*Selene.*
				Argyreioſus	*Argyreioſus.*

				Gymnetrus.	

THORACICI.

THORACICI.—Third Sub-order of OSSEOUS FISHES with perfect branchiæ *(continued)*.

- Body thick
  - compreſſed; remarkable from having the
    - head
      - ſimple
        - lips fleſhy; gill covers
          - ſpinous or denticulated — ACANTHOPOMATI
            - Trachichthys.
            - Lutjanus . . *Lutjan.*
            - Centropomus . *Centropomi.*
            - Bodianus . . . *Bodian.*
            - Sciæna.
            - Micropterus.
            - Holocentrus.
            - Perca . . . *Perch.*
          - without ſpines or denticulation — LEIOPOMATI . .
            - Hiatula.
            - Coris.
            - Gompheſus.
            - Oſphrenemus.
            - Trichopodus.
            - Monodactylus.
            - Plectorhinchus.
            - Pegonias.
            - Labrus.
            - Cheilinus.
            - Cheilodipterus.
            - Ophicephalus.
            - Helegymnoſus.
            - Sparus . . . *Spare.*
            - Dipterodon.
            - Cheilio.
            - Mullus . . . *Surmullet.*
        - jaws, projecting and oſſeous . . . . . OSTEOSTOMATI
          - Scarus . . . *Scare.*
          - Leiognathus.
          - Oſtorhinchus.
      - in general very large . . . . CEPHALOTI . .
        - Gobieſox.
        - Aſpidophorus.
        - Aſpidophoroides.
        - Cottus . . . *Bull-head.*
        - Scorpæna.
    - dorſal fin very long . . . . LOPHIONOTI . .
      - Coryphæna . . *Dorado.*
      - Hemipteronotus.
      - Coryphænoides.
      - Tænianotus.
      - Centrolophus.
      - Æques.
    - pectoral fins with ſome ſeparate rays or digittal proceſſes . DACTYLOTI . .
      - Dactylopterus.
      - Prionotus.
      - Trigla . . . *Gurnard.*
      - Peristedion.
  - round
    - fuſiform or thickeſt in the middle . . . . ATRACTOSOMATI
      - Scomber . . *Mackarel.*
      - Scomberoides.
      - Caranx.
      - Trachinotus.
      - Caranxomorus.
      - Cæſio.
      - Cæſiomorus.
      - Scomberomorus.
      - Gaſteroſteus . . *Stickle back.*
      - Centropodus.
      - Centronotus.
      - Lepiſacanthus.
      - Cephalacanthus.
      - Iſteophorus.
      - Nomatomus.
    - cylindric; pectoral fins . . . . .
      - united . . . PLECOPODI . .
        - Gobius . . . *Goby.*
        - Gobioides.
      - diſtinct or free . ELEUTHEROPODI
        - Gobiomorus.
        - Gobiomoroides.
        - Echeneis . . *Remora.*

ABDOMINALES.

CLASSIFICATION.

ABDOMINALES.—Fourth Sub-order of OSSEOUS FISHES with perfect branchiæ.

					Families.	Genera.
[illegible]	cylindric; mouth		at the extremity of a long snout		SIPHONOSTOMATI	Fistularia. Aulostomus. Solenostomus.
			not prolonged; lips not extended		CYLINDROSOMATI	Anableps. Cobitis . . . *Loche.* Misgurnus. Fondulus. Colubrina. Amia. Butyrinus. Tripteronotus. Ompok.
	conic, or compressed; the rays of the pectoral fin	free, distinct	the first only, or the first ray of the dorsal fin, stiff, sharp, and often denticulated, and used as a weapon		OPLOPHORI	Silurus . . . *Silure.* Macropteronatus. Malapterurus. Pimelodus. Doras. Pogonathus. Cataphractus. Plotosus. Ageneiosus. [illegible] Centranodon. Loricaria. Hypostomus. Corydoras. Tachysurus.
			many, flexible; the pectoral fins appearing to be of two parts		DIMEREDES	Chalodactylus. Cirrhitus. Polynemus . . *Polyneme.* Polydactylus.
		united; the opercule	covered with scales; mouth without teeth		LEPIDOPOMATI	Mugil . . *Mullet.* Mugiloides. Chanos. Mugilomorus. Exocetus . . *Flying Fish.*
			smooth; the jaws	not remarkable — dorsal fins with osseous rays	GYMNOPOMATI	Argentina. Hydrargyra. Atherina. Stolephorus. Buro. Clupea . . . *Herring.* Mystus. Clupanodon. Gastero, elecus. Mene . . . Dorsuarius. Xyster. Cyprinus . . *Carp.*
				not remarkable — one of the dorsal fins without osseous rays	DERMOPTERI	Salmo . . . *Salmon.* Osmerus. Corregonus. Characinus. Serrasalmus.
				much prolonged	SIAGONOTI	Elops . . . *Sein Fish.* Megalops. Esox . . . *Pike.* Synodon. Sphyræna. Lepisosteus. Polypterus. Scombresox.

STERNOPTYGES.—Sixth Order of FISHES.

	Genus.	
Contains only	Sternoptyx	*Sternoptyx.*

CRYPTOBRANCHIATI.—Seventh Order of FISHES.

		Genera.	
Ventral fins	distinct; upon the abdomen	Mormyrus	*Mormyrus.*
	wanting	Stylophorus	*Stylophorus.*

OPHICHTHOIDES.—Eighth Order of Fishes.

Genera.

- Aperture of the gills
  - lateral; the single fins
    - very plain . . . Murenophis.
    - not very apparent Gymnomuræna.
    - entirely wanting Murenollenna.
  - under the gullet, being a
    - double orifice . Sphagebranchus.
    - single orifice . . Synbranchus.

CLASS V. INSECTA.

Orders.

- Wings
  - none;
    - breathe by laminæ or gills; covered
      - with a calcareous crust; the shape of the body . . . 1. Crustacea.
      - usually with a horny substance, which has the form of shells . . . . 2. Testacea.
    - breathe by spiracles and air tubes, or cells; abdomen . . . .
      - indistinct; numerous feet . . 4. Polypoda.
      - distinct, and larger than the thorax
        - six feet 5. Hexapoda.
        - eight feet 3. Octopoda.
  - four; mouth
    - with jaws; having wings
      - of two kinds; the inferior folded
        - transversely . . . 12. Coleoptera.
        - longitudinally . . . 11. Orthoptera.
      - of one kind; the nervules
        - reticulated . . . . . 10. Neuroptera.
        - veinous . . . . . . 8. Hymenoptera.
    - without jaws; forming
      - a rostrum, not ceiled . . . . 7. Hemiptera.
      - a tongue, ceiled . . . . 9. Lepidoptera.
  - two; never have jaws . . . . 6. Diptera.

CRUSTACEA.—First Order of Insects.

Families. Genera.

- Head
  - united to the corcelet; the tail
    - short; corcelet more
      - broad than long Carcinoidea . . Calappa. Hepatus. Dromia. Cancer. Matuta. Portunus. Podopthalmus. Oecypodi. Porcellana. Grapsus. Pinnotheres.
      - long than broad Oxyrinchia . . Ranina. Orithyia. Dorippe. Leucosia. Maja.
    - long in proportion to the body . . . Macroura . . Pagurus . . *Hermit.* Albunæa. Hippa. Scyllarus. Palinurus. Galathæa. Astacus . . *Craw-fish.* Penneus. Palemon. Crangon . . *Shrimp.*
  - distinct and connected to the corcelet by articulation . . Arthrocephala Mysis. Squilla. Piecanima. Thalitrus. Gammarus.

TESTACEA.

TESTACEA.—Second Order of INSECTS.

			Families.	Genera.
The body covered by	a shell	in form of a buckler	ASPIDIOTA	Limulus. Calygus. Binoculus. Ozelus. Apus.
		composed of two valves	OSTRACODA	Lyncæus Daphnia. Cypris. Cythere.
	an integument the shape of the animal		GYMNOTA	Argulus. Cyclops. Polyphemus. Zoe. Branchiopes.

OCTOPODA.—Third Order of INSECTS.

		Families.	Genera.	
Head	not distinguishable; without antennæ, having jaws	ARANEIFORMIA	Aranea	*Spider.*
			Mygale	*Mygale.*
			Scorpio	*Scorpion.*
			Phrynus	*Phrynus.*
			Chelifer	*Chelifer.*
			Galiodes	*Galeodes.*
			Phalangium	*Shepherd.*
			Hydracna	*Water spider.*
	distinct and small; pediform palpi; no jaws; the mouth a sucker	SUCTARIA	Acarus	*Mite.*

POLYPODA.—Fourth Order of INSECTS.

		Families.	Genera.	
Feet	too numerous to be easily counted; body much elongated	LONGIFORMIA	Scutigera.	
			Scolopendra	*Centipede.*
			Polyxenus.	
			Julus.	*Julus*
			Polydesmus.	
			Glomeris.	
	fourteen; usually several pair of jaws, and four antennæ; body of an oval figure	OVIFORMIA	Physodes.	
			Oniscus.	
			Armadillo.	
			Cymothoa.	

CLASSIFICATION.

HEXAOPODA.—Fifth Order of Insects.

			Families.	Genera.	
Animal in the young ſtate	not changed in form	adhere to other animals	Parasitica . .	Pediculus	*Louſe.*
				Ricinus . .	*Bird Louſe.*
		tail furniſhed with ſetæ or briſtles	Seticaudata .	Podura . .	*Spring tail.*
				Lepiſma .	*Lepiſma.*
				Forbicina.	
	metamorphoſed; extraordinary powers of leaping		Transformia . .	Pulex . .	*Flea.*

DIPTERA.—Sixth Order of Insects.

				Families.	Genera.	
A ſucker	hard, projecting from the head, long, and often bent			Sclerostomata	Empis.	
					Bombilius.	
					Myopa.	
					Conops.	
					Stomoxis.	
					Aſilus . . .	*Hornet Fly.*
					Culex . . .	*Gnat.*
					Hippoboſca .	*Horſe Fly.*
					Chingia.	
					Chryſopſis.	
					Tabanus . .	*Great Horſe Fly.*
	concealed or wanting mouth	diſtinct	fleſhy, retractile, and terminated by two lips	Sarcostomata	Stratyomis . .	*Armed Fly.*
					Ceria.	
					Nemotelus.	
					Anthrax.	
					Bibio.	
					Rhagio.	
					Sicus.	
					Hypoleon.	
					Cyrtus.	
					Syrphus.	
					Dolichopus.	
					Ceyx.	
					Tetanocerus.	
					Cerechetus.	
					Coſmius.	
					Thereva.	
					Echinomya.	
					Sargus.	
					Mulio.	
					Muſca.	
					Cenogaſter.	
					Diopſis?	
			projecting in a flat proboſcis with palpi	Hydromia . .	Tipula . . .	*Crane Fly.*
					Ceratoplatus.	
					Scatopſus.	
					Pſychodes.	
					Hirtæa.	
		replaced by three points . .		Astomata . . .	Oeſtrus . . .	*Gad Fly.*

HEMIPTERA.—Seventh Order of Insects.

Elytra, or superior wings,		Families.	Genera.	
semi-coriaceous, cressed, and	broad; rostrum arising from the anterior part of the head	Frontirostria	Pentatoma.	
			Scutellera.	
			Podicerus.	
			Acanthia	*House Bug, and some others.*
			Cimex . .	*Bug.*
			Coreus.	
			Lygæus.	
			Gerris.	
			Hydrometra.	
			Reduvius.	
			Miris.	
			Ploiera.	
	very narrow; tarsi ending in vesicles	Physapoda . . .	Thrips.	
similar to the inferior wings, and not cressed	rostrum appearing to rise from the neck	Collirostria	Fulgora . .	*Fire Fly.*
			Tettigonia	*Small Grass-hopper.*
			Membracis.	
			Flata.	
			Cicadella.	
			Premecopsis.	
			Cercopes.	
			Delphax.	
	wings plain and extended	Planipennia .	Aphis . .	*Plant Louse.*
			Aleirodes.	
			Chermes .	*Gall Insect.*
			Coccus . .	*Cochineal Insect.*
			Psylla.	
hard and coriaceous; antennæ short; and posterior feet fitted for swimming		Remitarsea .	Ranatra . .	*Frog-hopper.*
			Nepa . .	*Water-Scorpion.*
			Naucoris.	
			Sigara.	
			Notonecta .	*Boat Fly.*

HYMENOPTERA.—Eighth Order of Insects.

Families: Genera.

- Abdomen
  - ſeſſile; a terebra projecting from the anus of the females . . . . SERRICAUDATA . . Urocerus *Tailed Waſp*. Tenthredo *Saw Fly*. Oryſſus. Sirex. Cymbex.
  - pedunculated; the inferior lip
    - longer than the mandibules; abdomen on a ſhort footſtalk . . . APIFORMIA . . Apis . . *Bee*. Eucera. Nomada. Andrœna. Hylæus. Bembex.
    - ſhort; abdomen
      - concave inferiorly; body metallic colour . . . . . . CHRYSIDA . . Chryſis . . *Golden Fly, or Gilded Waſp*. Panorpes.
      - not concave; ſuperior wings
        - folded, antennæ diffracted . . . . PENNIPLICATA . Veſpa . . *Waſp*. Maſaris.
        - not folded; antennæ
          - diffracted or filiform; abdomen round . . MYRMECEA . . Dorylus. Formica . . *Ant*. Mutilla.
          - neither diffracted nor filiform; number of joints
            - thirteen at moſt; abdomen
              - round, conic; live upon flowers . . ANTHOPHILA . . Philanthus. Scolia. Crabro. Mellinus.
              - compreſſed, enlarged, larvæ concealed in vegetable excreſcences . NEOTTOCRYPTA . Leucopſis. Chalcis. Diplolepis. Diapria. Cynips . . *Gall Fly*. Eulophus.
            - more than thirteen,
              - 17 to 30; deſtroy other inſects . ENTOMOTILLA . . Evania. Ichneumon *Ichneumon*. Fœnus. Ophion. Banchus.
              - 14 to 17; burrow in the earth . ORYCTERA . . Larra. Sphex . . *Savage, or Solitary Waſp*. Tiphia. Pompilus.

LEPIDOPTERA.—Ninth Order of Insects.

Families. Genera.

- Antennæ
  - enlarged . .
    - at the extremity . . . BACULICORNIA . Papilio . . *Butterfly*. Heſperia. Heteropterus.
    - in the middle like a ſpindle . FUSICORNIA . . Sphinx. . . *Hawk Moth*. Seſia. Zygæna.
  - not enlarged
    - filiform, often pectinated . FILICORNIA . . Bombix. Coſſus. Hepialus.
    - ſetaceous . . . . . . SETICORNIA . . Lithoſia. Crambus. Noctua. Phalæna . . *Moth*. Pyralis. Tinea. Allucita. Pterophorus.

CLASSIFICATION.

NEUROPTERA.—Tenth Order of Insects.

			Families.	Genera.	
The mouth	very visible	covered by the inferior lip; wings extended in repose	Odonata . .	Libellula . .	*Dragon-fly*
				Aeſhna.	
				Agrion.	
		projecting; wings covering the body when the inſect reſts	Stegoptera	Perla.	
				Termes . .	*Ticking Inſect.*
				Hemerobius	*Golden-eye.*
				Semblis.	
				Myrmeleon	*Lion-ant.*
				Aſcalaphus.	
				Panorpa .	*Scorpion-fly.*
				Raphidia.	
				Pſocus.	
	hardly to be diſtinguiſhed; no mandibles		Agnatha . .	Phryganea .	*Cadow-fly.*
				Ephemera .	*Day fly.*

ORTHOPTERA.—Eleventh Order of Insects.

				Families.	Genera.	
Poſterior legs	extremely long and ſtrong, for leaping			Grylliformia	Locuſta . .	*Locuſt.*
					Acheta . .	*Cricket.*
					Achrydium.	
					Gryllus . .	*Graſshopper.*
					Truxalis.	
					Tridactylus.	
					Gryllo-talpa	*Mole-cricket.*
	proportionate to the others; number of the articulations of the tarſus	five; corcelet	longer than broad . .	Deformia . .	Mantis . .	*Soothſayer.*
					Phyllium .	*Walking-leaf.*
					Phaſma . .	*Spectre.*
			broad, covering the head	Blatta . . .	Blatta . .	*Cockroach.*
		three; abdomen terminated by forceps		Labidoura . .	Forficula .	*Earwig.*

COLEOPTERA.—Twelfth Order of Insects.

				Sub-orders.
Number of joints or pieces in the poſterior tarſi	five to all the feet			1. Quinquetarsea.
	leſs than five;	four; the anterior with	five . .	2. Diversitarsea.
			four . .	3. Quadritarsea.
		three, and the ſame to all the other feet		4. Tritarsea.

QUINQUE-

QUINQUETARSEA.—Firſt Sub-order of Coleopterous Insects.

Families. — Genera.

- **Wing ſheaths**
  - **hard**
    - very ſhort, not covering the belly; antennæ moniliform . . . . **Brevipennia** . .
      - Staphylinus . . *Rove Beetle.*
      - Pæderus.
      - Oxyporus.
      - Stenus.
    - long, covering the belly; antennæ
      - ſetaceous or filiform; body
        - flat; the antennæ
          - not denticulated; tarſi
            - ſimple; prey upon other animals in the larva ſtate **Carnivora** . .
              - Anthia.
              - Cychrus.
              - Tachypus.
              - Carabus.
              - Caloſoma.
              - Brachinus.
              - Cicindela.
              - Colliurus.
              - Manticora.
              - Drypta.
              - Elaphrus.
              - Bembidion.
              - Olivina.
              - Scarites.
              - Nothiophilus.
              - Omophron.
            - for ſwimming . . **Remipedia** . .
              - Dytiſcus.
              - Hyphydius.
              - Haliplus.
              - Gyrinus.
          - denticulated; corcelet or ſternum pointed **Sternoxia** . .
            - Atopa.
            - Cebrio.
            - Elater.
            - Threſcus.
            - Bupreſtis.
            - Trachys.
        - round and elongated; their larvæ deſtroy wood . . **Teredilia** . .
          - Anobium.
          - Ptelinus.
          - Ptinus.
          - Melaſis.
          - Tillus.
          - Lymexylon.
      - club-ſhaped . .
        - laminated . . . . .
          - at one ſide, or ſerrated **Serricornia** . .
            - Lucanus . . *Stag Beetle.*
            - Platycerus . . *Elk Beetl*
            - Paſſalus.
            - Synodendron.
          - at the extremity . . **Lamellicornia** .
            - Geotrupes.
            - Copris . . *Dung Beetle.*
            - Aphodius.
            - Scarabæus . . *Ball-comber.*
            - Melolontha . *May Beetle.*
            - Cetonia.
            - Trichius . . *Hairy Beetle.*
            - Trox.
        - not laminated . . .
          - round and ſolid . . . **Solidicornia** . .
            - Hiſter.
            - Lethrus.
            - Anthrenus.
          - long, perfoliate . . . **Clavicornia** . .
            - Nicrophorus *Interrer, or Corpſe-Carrier.*
            - Silpha . . . *Protector.*
            - Nitidula.
            - Elophorus.
            - Hydrophilus . *Diver.*
            - Sphæridium.
            - Scaphidium.
            - Peltis.
            - Parnus.
            - Dermeſtis.
            - Byrrhus.
  - **ſoft**; corcelet flat; antennæ filiform, variable . . . . **Mollipennia** . .
    - Drillus.
    - Lycus.
    - Omalyſus.
    - Melyris.
    - Lampyris.
    - Malachius.
    - Telephorus.

DIVERSI-

CLASSIFICATION.

DIVERSITARSEA.—Second Sub-order of COLEOPTEROUS INSECTS.

Wing sheaths—

- soft, flexible; antennæ very variable; many blifter the fkin . . . . . . **FAMILY:** VESICATORIA . — **GENERA:** Dafytes. Sagria. Anthicus. Notoxus. Meloe. Lytta . . . *Bliftering Fly.* Cerocoma. Mylabris. Apalus. Zonitis.
- hard antennæ
  - filiform, often denticulated; wing sheaths
    - narrow . . . . . **FAMILY:** ANGUSTIPENNIA — **GENERA:** Sitaris. Oedemera. Necydalis. Ripiphorus. Mordella. Anafpis.
    - broad; inhabit woods . **FAMILY:** ORKEPHILA . . — **GENERA:** Helops. Sinopalpus. Ciftela. Calepus. Pyrochroa. Heria.
  - moniliform; fuperior wings or elytra
    - not confolidated; antennæ ending in a club
      - elongated; avoid the light **FAMILY:** LYGOPHILA . . — **GENERA:** Upis. Tenebrio. Opatrum. Pedinus. Sanotrium.
      - rounded; many live on fungi **FAMILY:** FUNGIVORA . . — **GENERA:** Boletopagus. Hypophlæus. Anitoma. Agathidium. Diaperis. Cnedulon. Tetratoma.
    - fo clofely applied to each other as to feem but one; the inferior or true wings wanting **FAMILY:** SOLIDIPENNIA . — **GENERA:** Elaps. Pimelia. Eurychora. Atris. Scaurus. Lepidium Erodius. Zaphofis [illegible]

CLASSIFICATION.

QUADRITARSEA.—Third Sub-order of Coleopterous Insects.

Antennæ			Families.	Genera.	
borne upon the ſnout or prolongation of the front			Rostricornia	Curculio	*Weevil.*
				Attelabus.	
				Brentus.	
				Anthribus.	
				Brachycerus.	
				Rhinomacer.	
				Bruchus.	
				Oxyſterna.	
				Ramphus.	
				Rhynchænus.	
not ſuſtained upon the roſtrum and	clavate in general; body	cylindric	Teretiformia	Boſtrichus.	
				Clerus.	
				Apate.	
				Scolytus.	
				Necrobia.	
		flat	Planiformia	Colydium.	
				Lyctus.	
				Trogoſſita.	
				Ips.	
				Mycetophagus.	
				Cucugus	
				Heterocerus.	
	commonly ſetaceous; larvæ live in wood		Lignivora	Prionus.	
				Lamia.	
				Cerambix	*Goat Chaffer.*
				Saperda.	
				Callidium.	
				Spondilis.	
				Rhagium.	
				Leptura	*Wood Beetle.*
				Donacia.	
				Melorchus	*Carrion Eater.*
	filiform; commonly live in ſociety upon the leaves of plants		Herbivora	Donacia.	
				Caſſida	*Tortoiſe Beetle.*
				Chryſomela.	
				Galeruca.	
				Altica	*Earth Flea.*
				Cryptocephalus.	
				Crioceris	
				Luperus.	
				Hiſpa	*Spinous Beetle.*
				Helodes.	
				Clythia.	
				Alurnus.	
				Erotylus.	
	of two joints, of which the laſt is extremely enlarged like a ball and furniſhed with a hooked proceſs		Globulicornia	Pauſus.	

TRITARSEA.—Fourth Sub-order of Coleopterous Insects.

Antennæ			Genera.	
long	clavate	villous, elongated	Daſycerus.	
		naked, perfoliate	Eumorphus.	
	nearly filiform		Eudomychus.	
ſhorter than the corcelet which is		applied to the wing ſheaths	Coccinella	*Lady bird.*
		ſeparate from the wing ſheaths	Scymnus.	

Supplementary Table ſhewing the Orders to which thoſe Inſects belong, which are without wings; but which are not the true Aptera.

Mouth			Orders.
with jaws; abdomen	ſeſſile	with elytra; jaws without the *galea*	Colioptera.
		with or without elytra; jaws covered with the *galea*	Orthoptera.
	pediculated tarſi with	five articulations	Hymenoptera.
		leſs than five articulations	Neuroptera.
without jaws	with a jointed ſnout; claws of the tarſi	turned round	Diptera.
		not turned round	Hemiptera.
	ſpiral tongue	ſcaly body	Lepidoptera.

CLASSIFICATION.

		Bursaria	*Bursaria.*
		Gonium	*Gonium.*

Classification, in *Botany*, is that proceſs by which plants are diſtributed into claſſes, to facilitate the ſtudy of them, and to fix them more firmly in the memory. Many ſchemes have been deviſed for this purpoſe, which have generally obtained the name of methods. The framers of theſe are diſtinguiſhed by Linnæus into heterodox and orthodox. The heterodox are thoſe who have not founded their methods on any of the parts of fructification. Of theſe the *Alphabetarii* have arranged plants according to the alphabetic order of their names; the *Rhizotomi* have taken for their guide the ſtructure of the roots; the *Phylophili* have attended ſolely to the form of the leaves; the *Phyſiognomi*, to the general habit of the plant; the *Chronici*, to its time of flowering; the *Topophili*, to its native place of growth; the *Empirici*, to its real or ſuppoſed medicinal virtues; and the *Seplaſtarii*, to the ſituation which it occupies in pharmacopœias. The orthodox, in the conſtruction of their various methods, have confined themſelves to ſome of the parts of fructification. They have either formed ſyſtems profeſſedly artificial, or have attempted to make ſome approximation to a method perfectly natural. Artificial ſyſtems unavoidably unite plants ſtrikingly different from each other, if they do but poſſeſs, in common, that ſingle character which has been ſelected for the baſis of the ſyſtem. They have been founded by different authors on the fruit, the corolla, the calyx, and the ſexual, or eſſential parts of the fructification. A method which aſpires to the elevated ſtation of a natural one, admits into any particular claſs, only thoſe plants which reſemble each other in a great number of particulars, or in ſuch as are of the greateſt importance, and the leaſt liable to variation.

In the article Botany, we have given a conciſe hiſtory of the ſcience, and of the improvements which have been gradually made in its progreſs to its preſent advanced ſtate. We alſo laid before our readers a detailed account of the ſyſtem of Linnæus, which we profeſſedly follow in this department of our work, admitting only thoſe occaſional alterations which more recent obſervations, and the diſcovery of a vaſt number of plants, unknown to the great Swediſh naturaliſt, ſeem to render expedient. We ſhall now, in fulfilment of the engagement there made to the public, lay before them a ſynoptic view of the other principal methods or ſyſtems. Linnæus, in his "Philoſophia Botanica," has arranged them according to the parts of fructification, which form their diſtinguiſhing character. But it appears to us, that a chronological order will be more advantageous, as it will ſet, in a clearer point of view, the aſſiſtance which each author has derived from his predeceſſors. We will only beg leave to correct, *en paſſant*, a material error in the ſynoptic table of the Linnæan claſſes. The general character of the ſixteenth, ſeventeenth, eigthteenth, nineteenth, and twentieth claſſes, ought to ſtand thus: "Stamens united in ſome of their parts, or attached to the piſtil."

I. *Cæſalpinus's method, publiſhed in* 1583.

Trees and ſhrubs	with the corculum, or embryo	at the apex of the ſeed	1.
		at the baſe of the ſeed	2.
Under ſhrubs and herbs	with ſolitary	ſeeds	3.
		berries	4.
		capſules	5.
	with two	ſeeds	6.
		capſules	7.
	with a triple principle	not bulbous	8.
		bulbous	9.
	with four ſeeds		10.
	with numerous ſeeds	Anthemides	11.
		Cichoraceæ, ſ. Acanaceæ	12.
		with a common flower	13.
		in follicles	14.
	deſtitute of both flower and fruit		15.

Cæſalpinus is the firſt botaniſt who availed himſelf of the hints thrown out by Geſner, and attempted a truly ſcientific arrangement of plants, founded on the parts of fructification. On this account he will always be entitled to our grateful reſpect; but we may alſo add, in concurrence with La Marck, that whatever may be the defects of his method, much worſe have ſince been ſubmitted to the judgment of the public. He is ſtiled by Linnæus a Fructiſt; and would have been completely ſo, if he had formed his claſſes with a little more logical preciſion. His eighth and ninth claſſes are properly one, with the common character of a three-celled capſule, or, as he quaintly ſtiles it, a triple principle; the difference of their roots might have given riſe to a ſubdiviſion, but ſhould by no means have been elevated to a claſſical diſtinction. The ſame may be ſaid of his eleventh, twelfth, and thirteenth claſſes. In the eleventh, the compound flower is radiate, conſiſting of ligulate florets in the ray, and of tubular ones in the diſk; in the twelfth, it is without a ray, and conſiſts entirely of ligulate florets; in the thirteenth, it is alſo without a ray, but conſiſts entirely of tubular florets. Theſe varieties in the form of the compound flower, afford obvious and convenient ſubdiviſions; but in all of them the claſſical character is exactly the ſame. The grand imperfection of this method, which it has in common with many ſucceeding ones, is the ſeparation of trees from herbaceous plants. Unable to relinquiſh a diſtinction as old as the age of Theophraſtus, and become venerable from its antiquity; at the ſame time unwilling, as it ſhould ſeem, to give ſimilar claſſical characters to plants of both his primary diviſions, Cæſalpinus has paſſed over what, at the firſt view, is moſt ſtriking in the fruit of trees, and has taken his character of the two claſſes from the ſituation of the corculum, or rudiment of the future plant, as it ſprings either from the apex, or from the baſe of the ſeed; differences which are always of difficult inveſtigation, and entirely beyond the reach of the common obſerver. In this, however, he has ſtrictly adhered to his leading principle as a Fructiſt.

II.—*Moriſon's method, firſt publiſhed at Paris,* 1669, *in a ſecond edition of Breyner's Hortus Regius Bleſenſis.*

Woody Plants.	Trees	1.
	Shrubs	2.
	Under-ſhrubs	3.
Herbaceous Plants.	Scandent or climbing	4.
	Leguminous	5.
	Siliquoſe	6.
	Tricapſular	7.
	Deriving their name from the number of capſules	8.
	Corymbiferous	9.
	Lacteſcent or pappous	10.
	Culmiferous	11.
	Umbelliferous	12.
	Tricoccous	13.
	Galeatæ or helmeted	14.
	Many-capſuled	15.

Herbaceous

Herbaceous Plants.	Bacciferous - -	16.
	Capillary or ferns -	17.
	Heteroclitæ, reducible to no clafs -	18.

Morifon's method is much inferior to that of Cæfalpinus, being farther removed from fimplicity, without approaching at all nearer to a really natural arrangement. His three claffes of woody plants are altogether unfcientific. His fourth clafs, which he places among the herbaceous plants, is a very heterogeneous affemblage of genera, without any refemblance to each other in the flower or fruit: and many of them with truly woody ftems. His fifth, fixth, feventh, eighth, thirteenth, fifteenth, and fixteenth are founded on the fruit; the fourteenth on the form of the corolla; the twelfth on the mode of inflorefcence; the eleventh on the general habit; the ninth and tenth fhould be united; as they now ftand, it is impoffible to determine on what principles they are feparated; the eighteenth includes the moffes, algæ, fungi, and corals.

III.—*Ray's firft method, publifhed in* 1682, *in a work entitled, "Methodus Plantarum Nova Synoptica, in Tabulis exhibita."*

Woody Plants.	Trees - -	1.
	Shrubs. - -	2.
Herbaceous Plants.	Imperfect - -	3.
	Without a flower -	4.
	Capillary - -	5.
	Graffy - -	6.
	With one naked feed -	7.
	Umbellate - -	8.
	Verticillate - -	9.
	Rough-leaved -	10.
	Stellate - - -	11.
	Pome-bearing -	12.
	Berry-bearing -	13.
	Many-podded -	14.
	With one regular petal	15.
	With one irregular petal	16.
	Tetrapetalous, filiquofe	17.
	Tetrapetalous, filiculofe	18.
	Papilionaceous -	19.
	Pentapetalous -	20.
	Frumenta, or the different kinds of corn, which afford food to men - -	21.
	Graffes - -	22.
	Grafs-leaved plants	23.
	Bulbous - -	24.
	Allied to the bulbous	25.

This method, like all the other productions of its great author, has uncommon merit. Its chief excellence arifes from its being a nearer approximation to a natural arrangement than the fcientific world had then feen. For this purpofe, though he paid particular attention to the fruit, which he thought of primary importance, he judged it expedient fometimes to feek for claffical characters from other parts of a plant. The 7th, 12th, 13th, and 14th claffes or families are founded entirely on the fruit. Ray very illogically calls them genera; fince he has, under each of them, fubordinate genera, analogous to thofe of Linnæus and all modern botanifts. The 17th and 18th are characterized partly from the fruit, and partly from the flower. The 15th, 16th, 19th and 20th depend entirely on the flower; the 8th and 9th on the mode of inflorefcence; the 10th on the texture; and the 11th on the pofition of the leaves; the 21ft and 22d on the general habit; the 24th and 25th on the root.

Of the defects of his fyftem no one was more fenfible than himfelf. Superior to the blind partiality which fo fondly attaches moft authors to the offspring of their own brains, he was always ready to give up what a fuller inveftigation of the fubject led him to difapprove. In fact, he never reduced this firft method to practice in all its parts. Of this we have fufficient proof in the alterations introduced into the "Hiftoria Plantarum," publifhed four years afterwards in 1686; and in the additional ones inferted in the "Synopfis Stirpium Britannicarum," the firft edition of which appeared in 1690. The moft glaring impropriety, in the original fketch, is the feparation of corn from the other claffes. This the author himfelf foon perceived, and in his letter to Rivinus, affixed to the fecond edition of his "Synopfis," frankly acknowledges. It is accordingly corrected in all his fubfequent works. The 17th and 18th claffes divide one natural family into two. This error alfo is found no where, but in the delineation of his firft method. The third clafs contains the fungi, lichens, and fubmarine plants; including corallines and other organized bodies, then fuppofed to be vegetables, but now univerfally affigned to the animal kingdom. The fourth clafs confifts of the proper moffes; the fifth of the ferns; thefe, agreeing with each other in having no confpicuous flower, he afterwards united; but the alteration can fcarcely be called an improvement. Not having had the good fortune to meet with the work, in which this method was firft offered to the public, we are not able to determine, with certainty, what he means by the vague epithet gramineæ or graffy, of which there are no traces to be found either in the "Hiftoria Plantarum" or the "Synopfis;" but, from its fituation in the original arrangement, compared with what occupies its place in thofe works, we fufpect that he intended by it what he afterwards called herbaceous plants, with an imperfect or ftamineous flower, in which are included humulus-lupulus, or hop; cannabis, or hemp; urtica, or nettle; rumex, or dock; polygonum, &c. &c. Thefe have a fingle feed in each flower, and leaves which, being generally entire, may, with fome grains of allowance, be ftiled graffy. We are the more inclined to adopt this idea, becaufe we can fcarcely think it poffible, that the found judgment of Ray fhould place this heterogeneous mixture in the fame clafs with the compound flowers. On this fuppofition it is not proper to make a fingle naked feed, the diftinguifhing character of the next clafs. In fact this character was foon dropt, and the term compound flowers fubftituted for it. In the "Hiftoria Plantarum" and "Synopfis" thefe compound flowers are diftributed among four diftinct claffes; but this alfo we can by no means think an improvement; they ought to have been only fubdivifions.

IV.—*Chriftopher Knaut's method, publifhed in* 1687.

Herbs with petals, and a flefhy fruit - -	Berry-bearing	1.
With membranous fruit.	Monopetalous	2.
	Tetrapetalous, with a regular flower	3.
	Tetrapetalous, with an irregular flower	4.
	Pentapetalous	5.
	Hexapetalous	6.
	Polypetalous	7.
	Many-capfuled	8.

Herbs

Herbs with naked fruit.	Gymnoſpermous	9.
	Solid	10.
	Pappous	11.
Herbs without petals.	Apetalous	12.
	Stamineous	13.
	Inconſpicuous	14.
	Imperfect	15.
Woody plants.	Trees	16.
Shrubs.	Shrubs	17.

This method is that of Ray, a little ſimplified, and placed in an inverted order. It has been applied only to the plants which are found in the neighbourhood of the Saxon Halle. There is an evident abſurdity in giving the epithet apetalous to one diviſion of apetalous plants in contradiſtinction to the others. But moſt theoretical botaniſts, and, indeed, naturaliſts in general, betray a lamentable ignorance of the rules of logic.

V.—*Herman's method, publiſhed in* 1687.

Herbs with petals, and a naked ſeed.	one-ſeeded,	Simple	1.
		Compound	2.
	two-ſeeded,	Stellate	3.
		Umbellate	4.
	four-ſeeded,	Rough-leaved	5.
		Verticillate	6.
	many-ſeeded		7.
With ſeeds in a pericarp,	bulbous,	three-capſular	8.
	capſule	Univaſcular	9.
		Bivaſcular	10.
		Trivaſcular	11.
		Quadrivaſcular	12.
		Quinquevaſcular	13.
		Siliquoſe	14.
		Leguminous	15.
		Many-capſuled	16.
	Fleſhy,	bearing berries	17.
		Bearing pomes	18.
Without petals,	calycled,	apetalous	19.
	glumoſe,	ſtamineous	20.
	naked,	muſcoſe	21.
Trees . . incomplete . . .		amentaceous	22.
	fruit fleſhy,	umbilicate	23.
		not umbilicate	24.
	not fleſhy, dry		25.

This is an elegant arrangement, founded almoſt entirely on the fruit. We are weary of pointing it out, but the diſcerning reader will at once perceive a ſimilar want of logical preciſion in the diſtribution of the apetalous plants. It would have ſtood better thus :

Apetalous, flowers with a calyx		19.
with glumes,	graſſes	20.
naked,	moſſes	21.

The 19th is a very multifarious claſs. The 21ſt, though only moſſes are mentioned, muſt include the whole of the Linnæan *cryptogamia.* The arrangement would have been more neat, and its author would have better ſupported his character as a Fructiſt, if he had not admitted the preſence and abſence of a corolla into his primary diviſion. The flowers, with only a calyx, would then have been diſtributed among the preceding claſſes, according to the nature of their fruit ; thoſe with glumes would have been placed among the plants with a ſingle naked ſeed, and might with propriety have been made a diſtinct order ; thoſe with naked flowers would have ſtood in their proper place at the foot of the ſeries. If the bulbous roots, which, as ſuch, are an embarraſſment to every method, had been equally diſregarded, Herman would have been completely a Fructiſt.

VI.—*Rivinus's method, publiſhed in* 1690.

Flowers perfect, ſimple, regular.		Monopetalous	1.
		Dipetalous	2.
		Tripetalous	3.
		Tetrapetalous	4.
		Pentapetalous	5.
		Hexapetalous	6.
		Polypetalous	7.
compound ;	florets regular		8.
	florets regular and irregular		9.
	florets irregular		10.
	irregular,	Monopetalous	11.
		Dipetalous	12.
		Tripetalous	13.
		Tetrapetalous	14.
		Pentapetalous	15.
		Hexapetalous	16.
		Polypetalous	17.
Flowers imperfect			18.

Rivinus has the honour of being the firſt Corolliſt. His method is very ſimple, and apparently eaſy ; but as it is entirely artificial, it has the diſadvantage of diſturbing natural affinities, and will occaſion great perplexity to the botanical ſtudent who attempts to reduce it to practice. He was alſo the firſt who perceived that the diſtinction of plants into trees, ſhrubs, under-ſhrubs, and herbaceous, is not ſtrictly ſupported by nature, and that, in a botanical point of view, it is of no uſe. In our preſent advanced ſtate of knowledge, it cannot but be ſurpriſing, that Ray was not convinced by the ſtrong, and as they appear to us, unanſwerable arguments addreſſed to him by Rivinus, in a letter printed in the ſecond edition of the " Synopſis ;" and that he perſevered to the laſt in keeping the trees and ſhrubs ſeparate, although he found himſelf compelled by incontrovertible facts to unite the under-ſhrubs with the herbaceous plants. In vain did Rivinus urge that the production or non-production of buds, by which Ray diſtinguiſhed the ſhrubs from the under-ſhrubs, was by no means a certain characteriſtic, and that nature does not warrant their ſeparation : our great naturaliſt perſiſted in his opinion with invincible obſtinacy. The hiſtory of ſcience ſcarcely affords a more ſtriking inſtance of the influence of preſcriptive authority and long prevailing habit, on a mind uncommonly enlightened, poſſeſſed of vigorous powers, and particularly eminent for the acuteneſs of its penetration. It is a conſolation to ſuch of us as cannot avoid feeling for the honour of our illuſtrious countryman, that Tournefort, his great antagoniſt, was equally blind. Both of them were in this reſpect ſo accuſtomed to darkneſs, that they could not endure the light of day.

VII.—*Tourne-*

VII.—*Tournefort's method, publiſhed in* 1694.

Tournefort was profeſſedly a Corolliſt, and ſeldom forſook his favourite principle. In the conſtruction of his 7th, 9th, and 17th claſſes he has called in the aid of the fruit; and in the 19th has had recourſe to the mode of infloreſcence; but, in all the reſt, the corolla, as it is either preſent or abſent, is the ſole object of his attention; conſidering alſo that his ſyſtem is truly artificial, he has broken natural families and united with them diſcordant plants much leſs than might have been expected. His 4th, 5th, 7th, 9th, 10th, 12th, 13th, and 14th claſſes are natural aſſemblages, with the exception of a few plants of a very different general character, which he has been induced to annex to ſome of them on account of the form of the corolla. Thus, for inſtance, in his fifth claſs he has inſerted chelidonium, epimedium, and potamogeton, which belong to widely different families, and in which the corolla itſelf is but imperfectly cruciform. It may be objected to the firſt claſs, that it not only makes ſad havock among natural affinities, but alſo contains plants with very differently formed corollas. No one would ſuppoſe *à priori*, that the ſhape of the flowers of campanula, convolvulus, tithymalus, (euphorbia, Linn.) glaux, ruſcus, malva, and galium can be properly expreſſed by the ſame word. It is alſo impoſſible to draw a deciſive line of diſtinction between this claſs and the next. The bell-ſhaped and funnel-ſhaped flowers approach each other ſo nearly that, independent of their interference with each other in regard to natural affinities, they cannot be ſcientifically ſeparated. The ſixth claſs is a motley collection diſtinguiſhed by very different prominent characters; and as La Marck obſerves, is of ſo diſproportionate a magnitude, that it includes nearly one-fourth of the perfect plants. The ninth claſs does not properly fit the place aſſigned it in the ſyſtem, ſince all its genera are not polypetalous, nor have they all regular corollas. The eleventh claſs is a receptacle for vagrants, collected together from all quarters, and for whom a legal ſettlement cannot be found. This, however, is an imperfection common to moſt artificial ſyſtems.

But whatever may be the defects of this celebrated method, it cannot be denied the praiſe of uncommon excellence. It is juſtly the boaſt of every ſcientific Frenchman, and, making due allowance for the time in which it was formed, can ſcarcely be too much admired. Its ſections or orders are taken from the ſituation of the germen; when it is inferior, in Tournefort's idea, *calyx abit in fructum;* the calyx finally becomes the fruit; when it is ſuperior, *piſtillum abit in fructum;* the piſtil finally becomes the fruit.

The celebrity of this ſyſtem has induced us to give a ſeries of figures to illuſtrate its general principles, as had formerly been done in the folio edition. And from the well-known excellence of the artiſts employed, we flatter ourſelves that it will be thought by our general readers as ornamental to our work as it will be inſtructive to thoſe who wiſh to ſtudy the ſubject. In all the figures, the letter *a* denotes the flower, *b* the fruit, and *c* the ſeeds. The numbers, prefixed to each, point out the plants which have been ſelected as moſt known, and beſt calculated to exhibit the particular characters of the plants contained in each claſs. Of theſe it may be neceſſary to give the following explanation. Cl. 5. Cruciform, fig. 1. Raphaniſtrum; Tour. (Raphanus Raphaniſtrum; Linn.) Jointed Charlock. 2. Burſa paſtoris; Tourn. (Thlaſpi Burſa Paſtoris; Linn.) Shepherd's purſe, &c.

Linnæus tells us that Ray began with being a Fructift, and finally became a Corollift. But on a comparifon of his two methods, as they are contrafted with each other by Linnæus himfelf in his "Philofophia Botanica," the obfervation fcarcely appears to be well-founded. In both his methods, Ray drew the character of his primary divifions, fometimes from the fruit, fometimes from the flower, and fometimes from other parts of the plant, as each of them in its turn feemed to himfelf to afford the moft ftrongly marked diftinctions. It is poffible that, irritated by Tournefort's numerous criticifms, he might feel a wifh to outdo his rival in his own way; but this wifh, if it ever really exifted, does not appear to have materially affected his general views.

In the fecond method, the fubmarine plants and the fungi correfpond with the imperfectæ, conftituting a fingle clafs in the firft. The mufci of the one, and the flore carentes of the other, are the fame. Thefe and the capillares, which had been united in the "Hiftoria Plantarum" and the "Synopfis," are again very properly feparated. We have already hazarded a conjecture that the apetalæ of the fecond method are the gramineæ of the firft. The planipetalæ, difcoidæ, corymbiferæ, and capitatæ of the former are all included in the gymnomonofpermæ of the latter. The tenth clafs of the fecond method, confifting of flowers with a folitary feed, has nothing equivalent to it in the firft. It was profeffedly formed to accommodate a few plants which have no other common character, and for which the author could not find another convenient place. It contains valeriana, dentellaria (plumbago, Linn.), limonium (ftatice, Linn.), mirabilis peruviana, linaria adulterina (thefium linophyllum, Linn.), pafferina tragi (ftellera, Linn.), agrimonia, and pimpinella fanguiforba (poterium, Linn.) This motley collection firft appears as a diftinct clafs in the "Synopfis," with the addition of thalictrum and fumaria. In the "Hiftoria Plantarum," and probably in the firft method, it was blended with the umbellatæ. The umbellatæ, verticillatæ, afperifoliæ, ftellatæ, pomiferæ, bacciferæ, multifiliquæ, leguminofæ, and pentapetalæ, have a place in both methods. The fifteenth clafs of the new method, or polyfpermæ, firft appears as a diftinct clafs in the

"Historia Plantarum." It there contains ranunculus, anemone, adonis, helleborus, malva, &c. geum and potentilla. In the new method, alisma, sagittaria, tormentilla, spirea filipendula, and clematis, are added, and the malvaceous plants removed to the 19th class, or monopetalæ. Linnæus has made a gross mistake in supposing that Ray intended the dipetalæ to form a distinct class. In fact, the dipetalæ in the new method are an anomalous appendage to the monopetalæ. Alisma and sagittaria, which are tripetalous, are placed in the 19th class. The 21st of the second method very properly unites the 17th and 18th of the first. The 23d class contains the bulbosæ and other liliaceous plants, with the addition of the bulbosis affines, which, with much greater propriety, had been kept separate in the first method. These consist of the orchideæ and scitamineæ. The 23d, with equal impropriety, unites the gramina and graminifoliæ, which form separate classes in the first method. The 25th class, or anomalæ, is peculiar to the new method; but the outlines of it first appeared, though with considerable variation, in the "Historia Plantarum." The 26th, or arundinaceæ, consists of the palmæ, which here appear for the first time in a professed method; they had already been noticed by Ray in the "Historia Plantarum," but are entirely omitted by Tournefort. The arrangement of the other trees, according to the difference of their fructification, which seems to have been entirely neglected in the first method, appears with considerable advantage in the second; but it does not materially differ from what had already been done by Tournefort, as well as by himself in his intermediate publications.

The chief glory of the second method arises from its taking the lead in distributing plants according to the number of their cotyledons. This, indeed, no one would suspect from the tabular view of it, as it stands in the "Philosophia Botanica;" nor does it appear in Ray's own table of contents, which Linnæus has very carelessly transcribed, and unwarrantably abridged. But the distinction is clearly pointed out and explained in the work itself, into which, one would think, Linnæus had never looked. "Floriferas dividemus" is the perspicuous language of Ray, "*in dicotyledones*, quarum semina sata binis foliis anomalis, seminalibus dictis, quæ cotyledonum usum præstant, è terra exeunt, vel in binos saltem lobos dividuntur, quamvis eos supra terram foliorum specie non efferant; & *monocotyledones*, quæ nec folia seminalia bina efferunt, nec lobos binos condunt. Hæc divisio ad arbores etiam extendi potest; siquidem palmæ & congeneres hoc respectu eodem modo à reliquis arboribus differunt quo monocotyledones à reliquis herbis." It is with peculiar satisfaction that we thus do justice to our great British naturalist, and restore to him the honour of which he has in a great measure been deprived. We readily acknowledge that we are proud of being able to call him our countryman, for he was in all respects as good as he was great. How far we may be unduly biassed by natural patriotic feelings, it is not in our power to determine: but, while our present convictions continue, we cannot allow a decided pre-eminence to Tournefort. Both of them, indisputably, possessed supereminent excellence, and we cannot but lament that they were not better friends. But *irritabile genus* is a character, which might have been extended by the poet much beyond his own fraternity.

Boerhaave is ſaid to have combined the ſecond method of Ray with thoſe of Herman and Tournefort. With the former he diſtinguiſhes the monocotyledones from the dicotyledones; but is more indebted to Herman than to Tournefort. His prevailing character is certainly that of a Fructiſt. His method was employed only in arranging the plants in the botanic garden at Leyden, and does not appear to have excited that attention which might have been expected from the extenſive medical fame of its excellent author. Its greateſt defect is the want of ſimplicity.

Chriſtian Knaut is a ſturdy Coralliſt. He poſitively denies the exiſtence of any apetalous flower, and of any naked ſeed. The former poſition is clearly contradicted by facts. The latter is nothing but a diſpute about the meaning of a term. Every one is acquainted with the integument of thoſe ſeeds uſually ſtiled naked. The only diſpute is, whether it ſhould be conſidered as part of the ſeed itſelf, or as properly its pericarp. In a ſtrictly philoſophical point of view, the latter opinion may be right; but to the practical botaniſt the former has a manifeſt uſe, and ought not to be entirely diſcarded.

XI. *Pontedera's Method, publiſhed in* 1720.

Uncertain.	- -	- - -	- -	- - - -	- -	1.
Certain.	Without buds	Without flowers.	- -	- - - -	- -	2.

Trees.	Calyx external only.	- -	- -	1[illegible]
	Calyx internal only.	- -	- -	14.
	Calyx external and internal.		- -	15.

Magnol was a Calyciſt; but he included under the term calyx both the perianth and the pericarp. Hence he is ſaid by Linnæus to be a Calyciſt combined with the Fructiſts.

XIII. *Linnæus's ſexual method* was introduced to the world in the firſt ſketch of his "Syſtema Naturæ," publiſhed in 1735; and farther developed and improved in the ſubſequent editions of that work, and alſo in the "Philoſophia Botanica," and the "Genera Plantarum." For a particular account of this renowned ſyſtem, ſee BOTANY; and for a critical examination of its excellencies and defects, chiefly reſpecting its preſervation or violation of natural affinities, ſee the names of its claſſes, Monandria, &c.

XIV. *Ludwig's method, publiſhed in* 1737.

Perfect flowers.	Petalous.	Regular.	Simple.	Monopetalous.	1.
				Dipetalous.	2.
				Tripetalous.	3.
				Tetrapetalous.	4.
				Pentapetalous.	5.
				Hexapetalous.	6
				Polypetalous.	7.
			Compound	florets regular.	8.
				Regular and irregular.	9.
				Irregular.	1[illegible]
		Irregular.		Monopetalous.	11.
				Dipetalous.	[illegible]
				Tripetalous.	[illegible]
				[illegible]	[illegible]
				Pentapetalous.	[illegible]
				Hexapetalous.	[illegible]
	Apetalous, furniſhed with a perianth.			Dubious.	[illegible]
Imperfect flowers.				Stamineous.	[illegible]
				Amentaceous.	[illegible]
				Powdery.	20.

Ludwig combined the very different methods of Rivinus and Linnæus. His principal diviſions are accordingly founded on the regularity and the number of the petals; his ſubordinate ones on the number of the ſtamens and piſtils. It is obvious, at firſt ſight, that his method muſt be altogether artificial.

XV. *Royen's method, publiſhed in* 1740

	Stony.	- - -	- -	Lithophytes.	20.

This is a happy eſſay towards a natural method founded on the cotyledons, the calyx, the corolla, the ſtamens, and the fruit. It manifeſts an attentive and deep inveſtigation of the ſubject; and is inferior to ſeveral which ſucceeded it only through its want of ſimplicity. Linnæus gave it the preference both to that of Haller and of Wachendorf, if we may form a judgment from the adverbs with which he qualifies them. Naturalem methodum in cotyledonibus, calyce, ſexu, aliiſque Royenus *pulchre*, Hallerus *erudite*, Wachendorfius *græce* quæſiverunt.

XVI. *Haller's Method, publiſhed in* 1742.

Fungi (funguſes) - - - -	1.
Muſci (moſſes) - - - -	2.
Epiphylloſpermæ (ferns) - - -	3.
Apetalæ (without petals) - - - -	4
Gramina (graſſes) - - - - -	5.
Graminibus affines (allied to the graſſes) - -	6.
Monocotyledones petaloides (monocotyledonous plants with petals) - - -	7.

Polyſtemones

Polyſtemones (ſtamens much more numerous than the petals) - - - - 8.
Diploſtemones (ſtamens twice as many as the petals) 9.
Scoſtemones (ſtamens equal in number to the petals) 10.
Mejoſtemones (ſtamens fewer than the petals) - 11.
Staminibus ſeſquialteris (ſtamens half as many more as the petals) - - - 12
Staminibus ſeſquitertiis (ſtamens one-third more than the petals) - - - 13
Quatuor ringentes (four-ringent) - - - 14.
Congregatæ (aggregate and compound) - - 15.

Whatever merit this method may poſſeſs in other reſpects, and notwithſtanding the indiſputable abilities and well merited reputation of its author, we cannot but regard it as a feeble attempt towards a natural one. It unites plants which nature has decidedly ſeparated, and ſeparates others which ought to be united. The 8th claſs, for inſtance, in which the ſtamens are much more numerous than the petals, muſt include the icoſandria, and polyandria of Linnæus, plants of widely different families: while ribes, which, in a natural arrangement, clearly belongs to icoſandria, muſt here be referred to the tenth, on account of the equal number of its ſtamens and petals.

Cryptanthæ (flowers concealed) - - - 19.

We agree with Linnæus in thinking that the ſeſquipedalian Greek names, of this method, are its moſt diſtinguiſhing characteriſtic. To the honour of a natural method, it has few pretenſions. Lucidus ordo is not one of its excellencies.

Linnæus

Linnæus did not profeſs to have conſtructed this method with a view to practical uſe, but only that ſtudents might become well acquainted with all the primary ſpecies, differences, and properties of the calyx. With this view he has broken the natural families without ſcruple.

XX.—*Bernard Juſſieu's method, firſt practiſed in* 1759.

Acotyledonous			1.
Monocotyledonous.	Stamens inſerted under the piſtil.	Hypogynous	2.
	about the piſtil.	Perigynous.	3.
	upon the piſtil.	Epigynous.	4.
Dicotyledonous.		Hypogynous.	5.
		Perigynous.	6.
		Epigynous.	7.

This method, founded on the relative ſituation of the ſtamens with reſpect to the piſtil, was employed in arranging the plants in the royal botanic garden at Trianon, under the patronage of Louis XV. but was not formally publiſhed to the world. It contains the germ of the more elaborate method, ſince formed by his well-known nephew, the preſent Anthony Laurence Juſſieu.

XXI.—*Gleditſch's method, publiſhed in* 1764.

Stamens on the receptacle.	Thalamoſtemonis.	1.
on the corolla.	Petaloſtemonis.	2.
on the calyx.	Calycoſtemonis.	3.
on the ſtyle.	Styloſtemonis.	4.
inconſpicuous.	Cryptoſtemonis.	5.

Gleditſch had evidently acquired ſome imperfect idea of the principle on which Bernard Juſſieu arranged the plants in the garden of Trianon. Willdenow, in his "Elements of Botany," erroneouſly gives him the honour of being the firſt who attempted an arrangement, founded on the ſituation of the ſtamens. His orders are taken from the number of the ſtamens.

XXII.—*Crantz's method, publiſhed in* 1766.

Cryptanthous.	1.
Incomplete.	2.
Compound.	3.
Graſſes.	4.
Palms.	5.
Liliaceous.	6.
Ringent.	7.
Papilionaceous.	8.
Cruciform.	9.
Umbelliferous.	10.
Columniferous.	11.
Calyciflorous, *i. e.* ſtamens and corolla, when preſent, inſerted in the calyx,	12.
Fructiferous, *i. e.* fruit beneath the flower.	13.
With few ſtamens.	14.
With many ſtamens.	15.

Moſt of the claſſes in this method are natural ones.

XXIII.—*Werniſcheck's method, publiſhed in* 1766.

Monopetalous.	Simple.	Two-lipped.	1.
		Four-cleft.	2.
		Five-cleft.	3.
		Six-cleft.	4.
		Anomalous.	5.
	Compound.	Tubular.	6.
		Ligulate.	7.
		Radiate.	8.
Polypetalous.		Petals, 2, 4, and 8.	9.
		4, cruciform.	10.
		3 and 6.	11.
		5 and 10.	12.
		Umbellate.	13.
		Papilionaceous.	14.
		Stamens more than 10.	15.
		Columniferous.	16.
Apetalous.		Calyx taking the place of a corolla.	17.
		Rude, or none.	18.
		Glumous, graſſes.	19.
		Clandeſtine.	20.

Werniſcheck is a Corolliſt, and, with the exception of his 13th, 15th, and 16th claſſes, has ſtrictly adhered to his principle. His arrangement is juſtly entitled to the praiſe of perſpicuity and elegance.

XXIV.—*Laurence Juſſieu's method, firſt publiſhed in* 1774.

Acotyledononous.	Cotyledons not exiſting, or inconſpicuous.			1.
Monocotyledonous.		Stamens	Hypogynous.	2.
			Perigynous.	3.
			Epigynous.	4.
Dicotyledonous.	Without a corolla.	Stamens	Hypogynous.	5.
			Perigynous.	6.
			Epigynous.	7.
	Corolla monopetalous.		Hypogynous.	8.
			Perigynous.	9.
			Epigynous.	
		Anthers	united.	10.
			Diſtinct.	11.
	Polypetalous.	Anthers	Epigynous.	12.
			Hypogynous	13.
			Perigynous.	14.
	Apetalous.	Monoicous or Dioicous.		15.
	Undetermined.			16.

This celebrated method is a much nearer approximation to a natural one, than any which had ever been before conceived; but it can be reported only as in a ſtate of progreſs, and cannot juſtly boaſt of perfection. In ſome points of view it is ſtill artificial. Its unrivalled excellence, however, inconteſtibly entitles it to an examination in full detail. But, as its very able author has been long employed in preparing a new edition, with conſiderable alterations, we ſhall refer our readers to the article NATURAL *Orders*, hoping that, before that part of our work goes to the preſs, we ſhall be able to lay before them his gradual advances towards a truly natural arrangement, with his lateſt ideas on the ſubject.

XXV.—*La Marck's method, publiſhed in* 1786.

1. Polypetalous.	Thalamiferous.	1.
	Calyciflorous.	2.
	Fructiflorous.	3.
2. Monopetalous.	Fructiflorous.	4.
	Calyciflorous	5.
	Thalamiferous angioſpermous.	6.
	gymnoſpermous.	7.
3. Compound.	Diſtinct.	8.
	Syngeneſious tubular.	9.
	ligulate.	10.
4. Incomplete.	Thalamiflorous.	11.
	Calyciflorous.	12.
	Diclynous.	13.
	Gynandrous.	14.
5. One-lobed.	Fructiflorous.	15.
	Thalamiferous.	16.
6. Cryptogamous.		17.

The

The fix claffes of this very elegant method are founded on the prefence or abfence of the corolla, with other characters of that organ, and have the fingular advantage of defcending, in a regular and confpicuous gradation, from thofe plants to which the author of nature has given, what may be called the moft numerous and the higheft endowments, to thofe which are but one degree removed from the mineral kingdom. The firft clafs La Marck confiders as the maximum of vegetable organization; moft of its genera have a calyx, a polypetalous corolla, a great number of ftamens, and often many piftils. It contains almoft all the plants which poffefs a remarkable irritability, as mimofa pudica, &c. hedyfarum gyrans, oxalis fenfitiva, dionæa mufcipula, the different fpecies of drofera, &c. and may be confidered as holding the fame rank in the vegetable creation as the Linnæan clafs *mammalia* does among the animal tribes. The fecond clafs is one degree lower. There is rarely found in it an indefinite number of ftamens and piftils in the fame flower. Its ftamens very feldom exceed ten, and in about two thirds of its genera are not more than five. Nearly all of them are attached to the corolla; whereas in the preceding clafs, they are generally inferted into the calyx or the receptacle. The lively imagination of the French naturalift is pleafed with tracing out its analogy to the animal clafs *aves*.

The third clafs betrays a ftill greater diminution either in the number or perfection of the effential organs. The proper flowers are almoft all unprovided with a feparate calyx, have only one naked feed, and are in many cafes abortive, in fome entirely deftitute of a piftil. In a fcale of comparative elevation, they are on a level with the *amphibia*.

The fourth clafs conftantly wants fome of the parts which conftitute a complete flower. The plants arranged under it have generally only a calyx, or nothing but fcales which imperfectly fuftain the office of a calyx. Its flowers are moft commonly fmall, without beauty, and difficult to inveftigate. Its ftamens and piftils are, moreover, frequently feparate from each other in diftinct flowers, and in fome cafes are not found on the fame plant. In point of relative completenefs, it may be fuppofed to occupy a ftation fimilar to that of the /.

The fifth clafs has, in feveral refpects, a ftill inferior character. Its feeds have only one lobe or cotyledon, and furnifh a fmaller quantity of nutritive matter to the rifing plumula. The full-grown plants are, in confequence, conftitutionally weaker, have frequently hollow ftems, and are more eafily crufhed or broken.

The fixth clafs is the minimum of vegetable excellence and dignity. Its plants have a fimpler organization; and, in the greater number of them, neither ftamens nor piftils have been difcovered. Connected with the preceding one by the affinity of the ferns to the palms, it defcends to the loweft degradation of organized matter. The algæ and the fungi can be compared only with the corallines, madrepores, &c. and like them can barely be faid to live. A more particular account of the fubdivifions of this method, and of its 94 natural families, will be found under the names of its claffes.

XXIV.—*Moench's method, publifhed in* 1794.

1. Thalamoftemon.	Stamens on the receptacle	
2. Petaloftemon.	- -	on the corolla.
3. Parapetaloftemon.	-	on leaves fimilar to petals.
4. Calycoftemon.	- -	on the calyx.
5. Allagoftemum.	- -	alternately on the calyx and petals.
6. Styloftemum.	- -	on the ftyle.
7. Stigmatoftemum.	- -	on the ftigma.
8. Cryptoftemon.	- -	not vifible.

This method profeffes to be an improvement of that conftructed by Gleditfch. Its author appears to have been as much indebted to Laurence, as his predeceffor was to Bernard Juffieu. We rather wonder at his temerity in offering it to the world, after the "Genera Plantarum fecundum Ordines naturales difpofita" had been fo widely circulated and fo generally admired. He has taken his orders from the difference in the fruit. But as fome of his claffes are very large, he has found it neceffary to make fubdivifions, in which he has had recourfe to other parts of the flower.

Adanfon, in 1763, publifhed what he calls a natural method, in which he has included all parts of a plant, without exception, from the root to the embryo of the future offfpring. It contains 58 orders; but in forming them he has eftablifhed no character fufficiently fimple or precife to render them at all intelligible, without labouring through his tedious verbofe details. His defcription of the 43d or leguminous plants, for inftance, fills eleven pages of his original work, without a poffibility of compreffing it into a narrower compafs; and, after all, the moft attentive ftudent will be in danger of confounding the characters of one order with thofe of another. We fhall, therefore, difmifs it without further notice. It would take up more room than it is worth. A fimilar objection, though not in quite an equal degree, may be made to the recent method of De Necker.

For an account of Gærtner's method founded on the fruit, which was drawn up without an idea of its being applied to any practical purpofe, but merely as an illuftration of his fubject, fee FRUIT.

CLASSIS PROCINCTA, in *Ancient Military Language.* This name or appellation was given by the Romans to either a fleet or an army ranged or drawn up in order of battle and ready to engage.

CLASSITÆ, in *Ancient Geography*, a people of Afia in Affyria, who occupied the borders of the river Lycus, according to Pliny. Hardouin fuppofes that the Cilici were fo called, by way of diftinction, from the Cilici who inhabited the mountains.

CLASSIUS, a river of Gallia Narbonnenfis.

CLASSIDIUM, a town of Italy, in Liguria, according to Polybius, or a village placed by Livy in Gallia Cifalpina; near which Viridomarus, king of the Gauls, was vanquifhed in fingle combat by M. Marcellus.

CLASTON, a town of Spain, in Bœtica, according to Strabo. Cafaubon calls it Caftulo.

CLATERNA, a town of Italy, in Gallia Cifalpina. Pliny gives it the title of a colony. Ptolemy annexes to it the appellation of "Togata," and the Itinerary of Antonine places it 30 miles from "Forum Cornelii," (Imola); M. D'Anville marks it S.E. of Bononia.

CLATHRI, in *Antiquity*, bars of iron, or wood, ufed in fecuring doors and windows.

There was a goddefs that prefided over clathri, called Clathra.

CLATHRUS, in *Botany*, (κλαθροι, *a lattice*, 129.) Linn. Gen. Mich. 93. Bulliard 10. Perfoon. 41. Mart. Lam. Clafs and order, *cryptogamia fungi.*

Gen. Ch. *Fungus* roundifh, confifting of a reticulated, latticed, hollow body; the ramifications connected on every fide. Linn. "*Volva* membranous; *pileus* roundifh, feffile, latticed with anaftomofing branches; *juice* flowing." Perfoon. "Seeds enclofed in the fubftance of the branches." Bulliard.

Sp. 1. C. *cancellatus,* Linn. Sp. Pl. 1. Lam. Pl. 887. Bul.

Bul. Pl. 441. Bolton Pl. 93. fig. 1. Sowerby 50. (C. ruber, Mich. tab. 93. Boletus purpureus & flavefcens, Tourn. 561. Fungus rotundus cancellatus, Bauh. Pin. 375. Barrel. ic. 1263, and 1265. "Branches numerous." W. *Volva*, burfting at its fummit into feveral fegments, and affording a paffage to the latticed pileus. *Branches* very porous, containing a gelatinous fubftance, which diffolves into a very fetid fluid, and thus difcharges the feeds. The plant varies in being either of a purple or yellowifh colour. A native of England and other parts of Europe. 2. C. *carolinianus*, Bofc. Dict. d'Hiftoire Naturelle, Pl. 26, B. "Branches four, anaftomofing only at the top." Bofc. A native of Carolina. Clathrus denudatus, nudus, & recutitus. Linn. See Trichia.

Clathrus is alfo the name of a fpecies of turbo, in the order of *teftacea*, belonging the clafs of worms.

CLATTE', in *Heraldry*, a term borrowed from the French to exprefs irregular lines, found in old paintings and engravings of arms not reducible to any other proper lines of heraldry, as the ingrailed, the indented, or the like.

CLAVA Herculis, in *Botany*, fee Zanthoxylum.

CLAVARIA, from *clava*, a club.) Linn. gen. 1332. Juff. 15. Vent. vol. ii. 18. Clafs and order, *cryptogamia fungi.*

Gen. Ch. "*Fungus*, with an even furface, oblong." "Uniform; upright, club-fhaped; feeds emitted from every part of its furface." Withering.

* *Stem with a head.*

Sp. 1. C. *gyrans*, With. Bolt. 112. 1. Batfch. 164. Willd. 7. 18. "Stem hair-like; head club fhaped, terminating, longifh, tapering at each end." *Stem* about half an inch long, rifing from a fmall bulb, very flender, pellucid, crooked at the bottom, twifting and untwifting as the air is moift or dry. *Head* whitifh. On rotten ftraw and leaves in woods and moift places. Sep. Oct. 2. C. *phacorhiza*, With. A flender, fimple, undulating thread, terminating rather bluntly at the apex. The fubftance at the bafe fomewhat refembles a bean or feed, fplitting to protrude a young plant. Sometimes the head is larger, and refembles a bodkin or knitting needle. 3. C. *gracilis*, Bolt. tab. iii. fig. 1. Sowerb. 232. *Stem* half an inch long, fmooth, flender, pellucid. *Head* enlarging, almoft imperceptibly from the ftem, more than an inch long, dufky white, of a wax-like appearance, terminating more or lefs acutely, differing in colour and texture from the ftem. Found in fhady places in garden ground that has been lately dug. 4. C. *acuta*, Sowerb. 333. (C. piftillaris, Bolt. 110. fig. 2, 3, 4.) Generally growing folitary, and varying much in fize. *Root* compofed of a few fhort fibres. *Stem* cylindrical, partly tranfparent, about the length of the head. *Head* always fharply conical, fomewhat opaque and mealy. 5. C. *phofphorea*, Sowerb. 100. (Rhizomorpha fragilis, Roth. Crypt. minus nota. 7-Himantia umbrina, Perfoon Meth. Fung. 73. Agaricum nigrum reticulatum compreffum, Mich. Gen. 125. tab. 66. fig. 3. Fungus niger compreffus, varie divaricatus et implexus inter lignum & corticem. Rai. Syn. 15 Sometimes parafitic between the wood and bark of trees. The plant figured by Mr. Sowerby was found in a wine-cellar in little St. Helens, London, creeping among faw-duft and bottles, and communicated to him by Mr. B. M. Forfter. When frefh it was remarkably luminous in the dark at the ends of the fhoots, where a very flender head is formed: but Mr. Forfter doubted whether this phofphoric appearance was natural to the plant, or owing to fome vinous moifture imbibed by it. 6. C. *filiformis*, Sowerb. 387. fig. 4. *Stem* branched, hairy. *Heads* terminating the branches, very flender, refembling thofe of the preceding fpecies but fmaller. Not uncommon among dead leaves, when thickly ftrewed on the ground. It is compofed of fibrillæ not unlike Byffus barbata Eng. Bot. tab. 701; but in drying fhrivels up almoft to nothing. 7. C. *tenuis*, Sowerb. 386. fig. 5. Refembling a little black hair, thickening upwards. Found on bits of rotting wood in a coal cellar in damp weather. 8. C. *herbarum*, Sowerb. 353. Perfoon Comment. de Fung. Clavæf. tab. iii. fig. 4? Like C. ophiogloffoides in miniature, but fmoother and of a more uniform colour, very fmall, with a diftinct head, which finally becomes fhriveiled and twifted. Growing on dead ftalks. 9. C. *obtufa*. Very fmall. Parafitic on fern-ftalks in autumn, either on the upright growing plant, or its decaying remains. *Head* larger in proportion to the ftem than in moft of the preceding fpecies; either fmooth or granulated like a fphæria; in the latter cafe, the ftem, when magnified, is a little hairy. In both varieties the head is folid, of a fomewhat friable texture, becoming a little horny in drying. 10. C. *minuta*, Sowerby, 391. Very minute. Head orange-coloured. Found on the bractes of dipfacus pilofus. 10. C. *coccinea*, Sowerb. 294. (Tremella purpurea; Hudf.? Sphæria tremelloides, With.). Seldom without a ftem, though apparently feffile, as may eafily be perceived by a perpendicular fection. *Head* fcarlet. Extremely common on rotten fticks in damp weather in autumn. 12. C. *polymorpha*, Sower. 276. Bafe fomewhat brown, and harder than the reft of the plant, which is of a waxy texture, differing much in fhape, and generally hollow. Often to be feen on decaying elm leaves in Kenfington gardens. 13. C. *parafitica*, With. Willd. Berol. 7. 17. (Sphæria parafitica, Woodw.) "Parafitic, club-fhaped, black, quite fimple; ftem cylindrical; head oblong-cylindrical, obtufe, coated with minute papillæ." Willd. This fingular fungus is always fixed to a lycoperdon. It refembles C. ophiogloffoides, but has a fofter fubftance, and fooner decays. *Root* confifting of many long, wiry, brown fibres, with which it entwines and covers the furface of the tuber, but never penetrates its fubftance. *Stem* flender, about an inch long. *Head* about half an inch long, oval, covered with minute fphæriæ. Found on a heath near Norwich and fent to Mr. Woodward by Mr. Pitchford. 14. C. *cylindrica*, Bull. tab. 463. fig. 1. Sowerb. 90. Whole plant of a wax-like friable texture. *Stem* cylindrical. *Head* elongated, in fome plants pear-fhaped. Found by Mr. Sowerby, in autumn, in a field between Stoke Newington and Hornfey. 15. C. *ephiphylla*, With. Dickf. Fafc. 3. tab. 9. fig. 10. Sowerb. 293. (C. phalloides, Bull. 463. "Club-fhaped, quite entire; head blunt, hollow, red, orange or faffron coloured," two or three inches high. *Stem* cylindrical, whitifh or pale yellow. *Head* roundifh, or oblong-egg-fhaped, fometimes refembling that of an agaric. In bogs and on half rotten dead leaves; in peat holes on Rombalds Moor, Yorkfhire, and in a deep running ftream near Tunbridge Wells. 16. C. *capitata*, With. (Sphæria agaricifolia, Bolt. tab. 130. Flor. Dan. tab. 540.) "Stem yellow, cylindrical; head egg-fhaped, chefnut coloured, dotted." *Root* black, fpongy, furrounded with a thick volva which is of the fame fubftance with the ftem. This volva is inclofed in another, which is dry, hufky, of a brownifh green colour, attached to the inner one by a few radical fibres. *Stem*, while young, folid and fmooth, when old, fiftular, furrowed, a little twifted; in both ftates, foft, pliable, and eafily fplitting into yellow fhining filaments. After being fhut up in a tin box all night, a fmall gelatinous drop was obferved, by Bolton, in every pore on the furface of the head; after an expofure to the warm funfhine for about an hour, the gelatinous particles dried up, and a white powder was copioufly difcharged.

 Found

Found in Ramfden Wood, near Halifax, in Yorkfhire. 17. C. *fpatulata*, With. Schmid. tab. 50. Flor. Dan. 658. (Helvella fpatulata; Sower. 35. H. clavata, Schæf. tab. 149. Dickf. 1. fafc. p. 19. H. feritoria, Bolt. tab. 97.) Battledore clavaria. *Root* a hard fibrous knob, a little thicker than the bottom of the ftem. *Stem*, while young, cylindrical, folid, foft, pliable, filvery white. As it advances in age, it becomes a little wrinkled on the furface, twifted, and fometimes torn, efpecially near the root. *Head* like the large end of a battledore for ftriking a fhuttlecock; at firft confifting of two equal membranes of a pale yellow colour, plain, united by their whole inner furface, refembling a fmall bladder with the two fides preffed together; as it advances in growth, the two fides become wrinkled, and branching veins begin to originate in that part of the ftem which runs into the head; at laft the fides feparate, and the head becomes inflated; when opened, nothing is found in it but a few downy, capillary filaments. In a ftate of perfect maturity, the head, on being touched, throws up its feeds in form of a fmoke, which rife with an elaftic force, and glitter in the funfhine like particles of filver. A very diftinct fpecies, but its genus not eafily determined; it being almoft equally allied to peziza helvella, lycoperdon, and clavaria. Firft difcovered, by the late excellent Mr. Crowe, in the plantations of Coftefy, near Norwich; found, by Bolton, in the plantations about Fixby-Hall, near Halifax. 18. C. *ferruginea*, Sowerb. 84. *Stem* a little rough on the upper part. *Head* refembling that of a fmall agaric, infide fomewhat pithy. Found under the fhade of firs in plantations, near Norwich. 19. C. *militaris*, Linn. Sp. 2. Lam. 2. Lam. Ill. tab. 888. fig. 1. "Club-fhaped, very entire; head either fcaly or granulated. *Var.* 1 Schæff. 290. (Sphæria militans, Bolt. 128.). Head fcaly, about four inches high, near two in diameter at the thicker part, folid, orange-brown. In fhady woods. *Var.* 2. Schmid. 5. fig. 2, 3. Vaill. Paris, tab. 7. fig. 4. Flor. Dan. tab. 657. fig. 1. (Sphæria militaris, Sowerb. 60.) *Head* granulated, orange brown or chocolate-coloured; much more flender than in the preceding fpecies, folid, yellow within, fometimes bifid at the apex. *Var.* 3. Bull. 496. 1. Buxb. 4. 66. 2. "Head granulated, yellow." *Stem* about an inch high, flender, tapering upwards, gradually thickening to form the head. *Head* an inch or an inch and half long, two or three tenths of an inch in diameter, thickeft in the middle, blunt at the end; in moift woods and bogs in autumn. La Marck fuppofes this fpecies to be only a variety of C, piftillaris; but he feems to be acquainted only with the firft variety. 20. C. *ardenia*, Sowerb. 215. Woolly at the bafe. *Stem* tomentous at the bottom, cylindrical, hollow. *Head* dilating upwards. In the younger plants the head is fomewhat pointed and covered with a lightifh mealy powder. In a more advanced ftate it becomes truncated, and covered with a browner powder; fplitting longitudinally in decay. Found by lady Arden, Nov. 29, 1798, in Nook-Park, near Epfom. It grows on rotten hazel fticks, fpringing from the under fide, half an inch or more under the earth, among decaying foliage. Its whole duration feems to be about a week.

** *Stem without a head, nearly undivided.*

21. C. *herculanea*, With. Var. 1. Bull. 244. Sowerb. 277. (C. piftillaris, β. Linn. δ. Hudf.) "Undivided, club-fhaped, folid, not granulated." The largeft of the genus; about three inches high, one or two in diameter towards the top, in the larger fpecimens much refembling the fhape of a pear, dull orange-coloured, beautifully white, and foft within. Found in Windfor foreft. 22. C. *vermiculata*, Lightf. 1057. Sowerb. 253. (C. piftillaris, Hudf. 638.) "Worm-fhaped, ochroleucous." Lightf. About two inches high, generally thickeft in the middl, often longitudinally wrinkled, varying from a ftraw-colour to an orange. 23. C. *tuberofa*, Sowerb. 199. *Root* tuberous. *Stem* tubular, pointed, growing on fticks, forcing its way through the bark. 24. C. *fufiformis*, Sowerb. 234. (C. piftillaris Bolt. 110?) Spindle-fhaped, tapering to a point. Subftance friable when frefh, pithy, moft firm in the external part. 25. C. *rugofa*, Lam. Ill. 888. fig. 2. Sowerb. 235. (C. piftillaris, Lightf.?) Subftance more tender than in the preceding, and moftly hollow, yellow, tipped with orange; young fpecimens fimple, blunt at the end; old ones laciniated in the upper part.

Obf. The laft five fpecies are all included under C. *piftillaris* of Linnæus and Hudfon. Withering has divided them into two, with feveral varieties under each, making a folid ftem the principal character of his herculanea; and a hollow one of his piftillaris; but, as the fame plant appears to vary in this refpect, in different ftages of its growth, it can fcarcely be thought a proper fpecific diftinction. We have followed Sowerby in making five fpecies, which appear to be fufficiently diftinct, and which may include the numerous varieties of different authors.

26. C. *tuberculata*, With. Schæff. 289. "Stemlefs, nearly of equal thicknefs, pale orange, whole furface ftudded with tubercles" About an inch and a quarter high, a quarter of an inch in diameter, rather flatted, fometimes flightly cloven at the top; tubercles deep orange, broadeft at the bafe, pointed, and tranfparent at the tip; interftices filled with a whitifh, cobweb-like fubftance. Grows on the ground, but rare, Aug. 27. C. *elveloides*, With. Dickf. Fafc. i. p 21. Wulfen in Jacq. Mifc. Auft. tab. xii. fig. 3. (Elvela carnea, Schæff. tab. 164.) "Growing in tufts, quite fimple, very thick, united at the bafe, inverfely pyramidal, ftriated." Two inches high, one in diameter; when young flefhy; when older woody, branched, compreffed, fomewhat funnel-fhaped, truncated; margin plaited, curled, brown, with a tinge of purple without, whitifh, or yellowifh within. Woods on the ground, about the trunks of trees, Aug. and Sept. 28. C. *ophioglofsoides*, Linn. Sp. Pl. 3. Lam. 3. Vaill. Paris, tab. 7. fig. 3. Mich. Gen. tab. 87. fig. 4. Schæff. tab. 237. Flor. Dan. tab. 1076. fig. 2. Schmid. 25. Bull. 372. Bolt. 111. fig. 2. Sowerb. 83. (Mufcus clavatus, Pluk. tab. 47. fig. 3.) "Club-fhaped, quite entire, compreffed, blunt." About two inches high, near half an inch in diameter in the broadeft part; always wholly black on the outfide, white within; when young, folid and fmooth; when older, hollow, fhrunk, depreffed, furrowed or wrinkled. In moift paftures, Sept. Oct. 29. C. *lutea*, Lam. 4. Mich. Gen. tab. 87. fig. 5. Hall. Helv. n. 2207. "Horn-fhaped, quite fimple, fmooth." From fix to nine lines long, gold-coloured, flender, hollow, a little pointed at the top, curved, tender. Found by La Marck in the neighbourhood of Rouen. There is a variety a little larger, growing in tufts, figured by Mich. tab. 87. fig. 11. (C. cefpitofa, Jacq. Mifc. ii. tab. 12. fig. 2?) 30. C. *fimbriata*, With. "Undivided, hollow, clofed, and pointed, or open and fringed at the end." Whole plant covered with a greyifh powder. Near half an inch high, about the thicknefs of a pin, greenifh at the bottom, white above, tapering. Found by Dr. Withering among mofs, Oct. 31. C. *cornea*, Withering. Batfch 28. 161. Sowerb. 40. (C. aculeiformis, Bull. 463-4. Sibth.) "Red orange; fimple or cloven, nearly cylindrical, obtufe, gelatinous, folid." Scarcely a quarter of an inch high, often fticking together

from

from their glutinous fubftance, though horny and brittle when dry. With. from Batfch. Sowerby's figure does not perfectly accord with Withering's defcription, though both make the fame reference to Bulliard. In Sowerby's figure, the ftem appears flatter, deeply laciniated, and fometimes cloven almoft to the bafe into three or more fegments.

*** *Stem branched.*

32. C. *elegans*, With. —— Bolt. tab. 115. (C. coralloides, Var. Bull. 496.—Sowerb. 278.) "White, fometimes branched, upright." Four or five inches high. *Root* hard, brown, fibrous. *Stem* fometimes fimple, club-fhaped, wrinkled, longitudinally furrowed; fometimes a little branched; all the divifions obtufe. In both ftates, while frefh and growing, of a pure filvery white, and, if viewed between the eye and the light, refembling the fineft virgin wax. In decay it changes to a pale brown colour, and foon difappears. Sept. Withering thinks Bolton right in keeping it diftinct from C. coralloides, as it connects the unbranched with the branched fpecies. 33. C. *coralloides*, Linn. Sp. Pl. 6. Lam. 7. With. Tourn. 332-6. Barr. 1259, 1260, 1261, 1262. Schœff. 170, 172, 174, 175, 176, 177. 285, 286, 287. Bull. 222, 354, 358, 496. Lam. Ill. 888. fig. 3. Bolt. tab. 113. Sowerb. 278. (Fungoides ramofum maximum, braffícæ cauliflorae facie et magnitudine, Dill. in Rai. Syn. ed. iii. p. 16, communicated by Dr. Richardfon, who, in 1703, found plants which weighed two or three pounds. They grew in a meadow at Bierly-hall near Bradford, Yorkfhire.) "Branches crowded, much divided and fubdivided, unequal." It varies much in colour, being either white, grey, purple, yellow, or olive-coloured; but may always be diftinguifhed from C. piftillaris, by growing from one bafe, and being much branched. It is fometimes as large as a cauliflower. The whole fpecies is efteemed on the continent one of the beft of the fungous tribe for the table, and is eaten by the Germans under the name of *Ziegenbart*. Dr. Withering affures us, from his own experience, that the white and grey varieties may be eaten with fafety. 34. C. *faftigiata*, Linn. Sp. Pl. 7. Lam. 6. Bull. 358, D. E. Bolt. tab. 112. fig. 2. and tab. 113. fig. 6. (Fungoides coralliforme luteum fætidum et minus ramofum, Dill. in Rai. Syn. ed. 3. p. 479. tab. 24. fig. 5.) "Yellow; branches crowded, of equal height." Bulliard is inclined to think it only a variety of coralloides. But, according to Mr. Woodward, it differs from that fpecies in having feveral ftems very flightly connected at the bafe, which are either fimple, or little branched, approaching very near to C. piftillaris, but fpecifically diftinct from both. In the young plants figured by Bolton in tab. 112. fig. 2, the tops of the branches are entire, and truncated; in the older ones, tab. 113, C. pointed teeth fhoot out, which gradually become larger, and fometimes branched. Woods and paftures, Aug. Oct. 35. C. *coriacea*, Willd. Bull. tab. 452. fig. 2. "Branches flattifh, grooved, fringed at the end, grey, changing to black brown;" about two inches high, of a foft but elaftic fubftance. It differs from C. coralloides, and C. faftigiata, in the longitudinal grooves. Found by Dr. Sibthorpe in Shotover plantations, Oxfordfhire, Oct. 36. C. *mufcoides*, Linn. Sp. Pl. 8. Lam. 5. With. Bolt. tab. 114. Sowerb. 157. (C. corniculata, Schœff. tab. 173. Fungus parvus luteus ramofus, Rai. Syn. tab. 24. fig. 7.) "Pale yellow, repeatedly branched, taper-pointed, unequal." From two to five inches high. It agrees with C. faftigiata, in being nearly diftinct at the bafe, and with C. coralloides, in being always much branched, but differs from both in having the extremities of the branches fharp-pointed. Branches feveral times dichotomous; terminating forks fometimes of unequal length; fometimes diverging at their origin, and converging near the point. Luxuriant fpecimens are the fize of a man's fift; the branches much fwelled at the divarications, and much entangled together, but all united at the bafe, Bolt. Heaths and dry woods, Oct. 37. C. *laciniata*, With. Bull. 415. 1. Jacq. Mifc. 14. 1. Schœff. 291. Sowerb. 158. (C. deformis. Var. β. γ. Lam. Encyc. Vaill. tab. 8. fig. 2, 3. La Marck's Var. α of his deformis is C. *cornutus*, Schœff. tab. 289.) "Flat, thin, membranous, jagged, and fringed at the top." From one to two inches high, irregular in fhape, much rooted in the earth, fpreading elegantly in all directions, and feeming to depend on the contiguous herbage for fupport. *Stems* uniting at the bottom, purplifh brown, covered with a fine mealy white, which eafily rubs off; branches often like an expanded hand, whitifh, or yellowifh-brown; the ends jagged, fet with feveral pointed projections, and tipped with reddifh brown, Aug. 38. C. *anthocephala*, With. Sibth. Bull. 452. 1. Sowerb. 156. "Fan-fhaped, lobed, rufty red; ftem fhort, cylindrical, hairy." Of a tough woody texture, nearly two inches high. *Stem* expanding upwards into feveral fegments, which are fcolloped at the end, and paler than the reft of the plant. Oct. 39. C. *hypoxylon*, Linn. Sp. Pl. 5. Lam. 10. With. (C. cornuta Bull. 180. Sphæria hypoxylon, Sowerb. 55. Sphæria digitata, &c. Bolt. tab. 129. *a*, *b*, *c*, *d*. Coralloides ramofa, nigra, compreffa, apicibus albis, Tourn. 565. Lichen agaricus nigricans, Mich. gen. tab. 55. fig. 1.) "Branches refembling horns, compreffed." Very woolly when young, and very black, rather woody, white, and fibrous within, fometimes fingle, or occafionally forked, with the extremities more or lefs acute; fometimes with the fummits compreffed, palmated, or digitated, and covered with a white farinaceous powder, which continues on them from October to March. 40. C. *digitata*, Linn. Sp. Pl. 4. Lam. 11. With. Schœff. tab. 328. Sowerby. 69. (Sphæria digitata, Woodv. Bolt. tab. 129. fig. 2. *f*. Bull. tab. 220. Agaricus digitatus niger, Tourn. 562. Lichen agaricus terreftris, digitatus niger, Mich. gen. tab. 54. fig. 4.) "Branched, woody, black." Linn. "Thick, folid, conical, rough," With. Subftance like cork, tending to a cylindrical figure, from one to two inches high, from a quarter to three quarters of an inch in diameter, fometimes rather branched, white at the top while young. *Seeds* lodged in little cells near the furface, which cells are not vifible till the hairs fall off. Bull. Dr. Waller, in fome curious obfervations communicated to Dr. Withering by the Rev. Mr. Dickenfon, has given it as his opinion, that the plants defcribed by Linnæus under the names of C. hypoxylon, C. digitata, and C. ophiogloffoides, are but one fpecies, which he propofes to call C. villofa. According to him, C. hypoxylon is the moft common appearance of the *male* plant; C. digitata of the *female*; and C. ophiogloffoides is a variety of the *female*. The female plant begins to fpring at the fame time and in the fame place with the male, *i. e.* about the end of September, and generally in fhady woods, but rifes only to half its height. They grow always in clufters together, but never proceed from the fame root. After the male plant has fhed its pollen in November, it begins to decay, and in the fpring entirely difappears: whereas the female plant continues to grow vigoroufly till about the middle of April, when the feeds being ripe, the head burfts in feveral places and falls off. Thefe facts, if fufficiently afcertained, fatisfactorily fhew the diftinction of the fexes. With regard to C. digitata, Dr. Waller obferves, that Linnæus has mifunderftood the term digitatus,

Strahan and Prefton,

digitatus, as applied by Tournefort, Vaillant, and others, to two varieties of the plant, not becaufe they are fingered like the human hand, but becaufe their fingle head, in figure and fize, has fome refemblance to a human finger. In oppofition to this ftatement, it is, however, neceffary to add, that Mr. Sowerby has obferved, that C. digitata commences its growth very early in the fpring, and ripens its feed-veffels annually in autumn. It is alfo worthy of notice, that Mr. Woodward, a very diligent and accurate obferver, could never perceive any appearance of fpherules on C. ophioglof-foides. 41. C. *cupreffiforme*, With. (Sphæria digitata, Bolt. tab. 129. fig. g.) "But little branched; head conical, fupported on a ftem." Mr. Woodward thinks this plant effentially different from the preceding one. *Stem* about half an inch high, fimple, or only once divided. *Head* about the fame length, refembling a cyprefs tree in miniature. On decayed wood. 42. C. *tomentofa*. Lam. 10. "Branched, coriaceous, cloathed with a reddifh brown pubefcence; little branches fomewhat palmated at the top." Growing in expanded tufts; not more than an inch high. Pubefcence fhort, cottony, with the appearance of velvet. Eafily diftinguifhed from every other known fpecies. In habit refembling coralloides ramofum ex rufo carneum platyceron of Micheli, (tab. 88. fig. 3.) which is, perhaps, a variety. Found by La Marck in a mine at Schemnitz, in Hungary, on the wood which fupported the roofs of the galleries. 43. C. *farinofa*, With. Dickf. Fafc. 2. p. 25. Sowerb. 308. (Ramaria farinofa, Holm in nov. act. dan. 1. fig. 6.) "White, mealy; branches fhort, truncated, crenulate." Solitary. *Stem* upright, fomewhat angular, a little compreffed; branches unequal, thicker towards the end. When the white meal is rubbed off, the plant appears yellow. Woods, on the chryfalis of infects. 44. C. *byffoides*, Sowerb. 335. "Small, delicately white." *Stems* branched, forming irregular intricate tufts, refembling a byffus, or rather a minute coral. Found on old ftumps of trees.

Mr. Woodward and other recent botanifts have removed fome of thefe fpecies to fphæria, in confequence of their agreement with that genus in the ftructure of their feed-veffels. But Schmidel has demonftrated a fimilar ftructure in ftill other fpecies of clavaria, and on a more accurate examination of the plants in a ftate of compleat maturity, it may probably be found in all; fo that the two genera muft on this ground be united into one. But the difference in their general habit is fo great, that Withering has thought it beft to keep them diftinct. For a fimilar reafon we have retained C. hypoxylon, &c. in the prefent genus where Linnæus placed them; convinced that, though a new arrangement will hereafter be neceffary, we are not as yet in poffeffion of fufficient knowledge to eftablifh one on a folid foundation. La Marck has retained all the Linnæan fpecies of clavaria, with the addition of three others; but Poiret, his fucceffor in the botanical part of the Encyclopedie Methodique, has removed militaris, hypoxylon, and digitata to fphæria.

Juffieu has given the following character of his clavaria: "Somewhat flefhy, growing either on the ground, or on other plants; either club-fhaped, fimple, oblong, or branched like corals; the little branches fwelling at the tip, with projections refembling nipples." By this definition he has excluded the firft five fpecies of Linnæus, *viz.* piftillaris, militaris, ophiogloffoides, digitata, and hypoxylon. Thefe, under the generic name of hypoxylon, he has removed to the order of algæ, and affociated with the lichens. Ventenat has not adopted this new genus.

CLAVARIUM, in *Ancient Military Language*, an allowance to common Roman foldiers for purchafing fhoes and boots, or harnefs for the legs (called caligæ), and which were fet full of nails. They raifed frequent mutinies, demanding largeffes of the emperors under this pretence.

CLAVATA-VESTIMENTA, in *Antiquity*, habits adorned with purple clavi, which were either broad or narrow. See CLAVUS.

CLAUDE, JOHN, in *Biography*, a highly celebrated French Proteftant divine, was born at Suavetat, in the Agenois, in the year 1618 or 1619. His early education was conducted by his father, who was alfo a minifter, and a man of learning; he was afterwards fent to finifh his ftudies in philofophy and theology at Montauban, where he was ordained in 1645. After having fucceffively ferved two churches of inferior confequence in the country, each for a fhort period, he accepted an invitation from the church of Nifmes, which was efteemed one of the firft in the Proteftant intereft in France. There was a Proteftant college at this city, and Mr. Claude employed his leifure time in delivering a private courfe of theological lectures to the ftudents, who gladly availed themfelves of the affiftance of his great learning and abilities. He had paffed eight years in this fituation, agreeably and ufefully employed, and univerfally refpected by all who had the happinefs of his acquaintance, when a circumftance occurred which obliged him to remove. He had the misfortune to oppofe the efforts of a man who had been gained over by the court, or catholic party, to bring back the Proteftants to the Roman communion; and an order of council was in confequence iffued to forbid him to officiate any longer in Languedoc. On receiving this prohibition he went to Paris, in hopes of being able to get it refcinded; he remained there fix months, but could not fucceed in the object of his journey. During his ftay at Paris, he was prevailed upon by madam De Turenne to write an anfwer to a work which had juft been publifhed by Meffrs. De Port-Royal, "On the Perpetuity of the Roman Catholic Faith refpecting the Eucharift," which was principally defigned to convert her hufband, marfhal Turenne, to the court tenets. Mr. Claude's anfwer led to a controverfy of fome length, in which he appeared with great advantage; but it was not probable he could fucceed in the firft object of his undertaking, the prefervation of marfhal Turenne to the Proteftant intereft, when other inducements, more powerful in the eftimation of a courtier than religious fcruples, weighed on the other fide. From Paris, Mr. Claude went to Montauban, the place of his education, where he accepted the charge of a church. After he had refided here four years, the Port-royalifts difcovered, by the bafeft artifices, that he was preparing an anfwer to their elaborate vindication of the original publication on the "Perpetuity," and made intereft to obtain another order of council to forbid him the exercife of his profeffion at Montauban. This occafioned him another journey to Paris, where he remained nine months, with as little fuccefs as had attended his firft application on a fimilar errand. At this time, 1666, he received a moft flattering invitation from the reformed church of Paris, which affembled at Charenton, and accepted the charge of being one of its paftors. Charenton being the metropolitan church of the French Proteftants, Mr. Claude had an opportunity of exercifing his talents with the greateft advantage to their caufe, and on many occafions rendered them effential fervices by his publications, and by his excellent conduct at fynods and confiftories. His firft publication in his new fituation comprifed two additional tracts againft the work of the Port-royalifts on the Eucharift. After this, Dr. Nicole publifhed an attack upon the Proteftants, in a work entitled, "Well-grounded Prejudices againft the Calvinifts;" which drew from Mr. Claude an anfwer in two

volumes

volumes quarto, entitled, "A Defence of the Reformation," which has been regarded as the ablest work ever published on the subject. He printed also some sermons, under the title of "The Parable of the Wedding Feast." At the request of mademoiselle de Duras, who was a member of his church, he had, in 1678, a long private conference with Bossuet, the bishop of Condom, afterwards of Meaux, which was conducted on both sides with all the talents these able adversaries could call forth. Of this disputation Bossuet first published an account, in which he considered himself as the victor; but Claude afterwards published his replies, claiming, with equal confidence, the honour of the day as his own. In 1682 he published anonymously a small work, entitled, "Considerations on the Circular Letters of the Assembly of the Clergy of France of the Year 1682." The letters to which it was a reply had been written and circulated by the Catholic clergy with the view of bringing back the Protestants to their communion. Shortly after this, Claude published another small piece of a more practical kind, "On Preparation for the Lord's Supper." Thus did he actively employ himself in the cause of the Reformation, until the clergy succeeded in the great measure which they had long laboured to effect, the revocation of the edict of Nantz. This fatal decree was registered in parliament, and received the sanction of law, on the 22d of December 1685. The longest period which was granted to the Protestant clergy to quit France was fifteen days; but so eager were the exulting bishops to get fairly rid of their old adversary, that an exception was made to the case of Claude, who received special orders to depart the kingdom in twenty-four hours! On the 23d of December, therefore, in compliance with this injunction, he set out for the Hague, where his son was minister of the Walloon church. He was received on his arrival with the greatest kindness by persons of the highest distinction; particularly by the prince of Orange, who granted him a pension for his maintenance. He enjoyed the bounty of his benefactor, however, only for a short period; as he died, after a short illness, in January 1687. During his residence at the Hague, he published a work, entitled, "The Complaints of the Protestants of France;" which was designed to expose the conduct of the bishops of France in their persecution of his party. It was well received by the friends of the reformation on the continent; but was, of course, execrated in France, and in England was ordered by James II. to be burnt by the common hangman. After his death, his son, Mr. Isaac Claude, published his posthumous works in five volumes 8vo.

Mr. Claude did not possess many requisites for a public speaker. His person was bad, and his voice deficient in those qualities which are calculated to impart the charms of melody and persuasive fascination to the eloquence of public discourse. His style and language, although not distinguished by elegance, were, nevertheless, correct, vigorous, and animated; and if they were not adapted to amuse the fancy and captivate the feelings, seldom failed to convince the understanding and improve the heart. His writings prove him to have possessed a large share of learning, and justly claim for him the highest reputation as a controversialist. To this it must be added, that his private life was truly excellent; he had imbibed the genuine spirit of the religion he taught; and manifested, in the whole of his conduct, a piety and devotion, a charity and benevolence, an integrity and uprightness of character, which reflect the highest lustre on his name and memory. Bayle. Nouveau Dict. Historique, Paris 1804. Robinson's Life of Claude.

CLAUDE, Le Jeune, or Claudin, in *Biography*, the most renowned French musician of his time, was a native of Valenciennes. He was an early follower of Calvin; but flourished somewhat later than Goudimel, with whom he is often confounded; both having the name of Claude, both being Hugonots, both great musicians, and both in high favour with the Calvinists for setting Clement Marot's musical translation of the Psalms to music for their temple worship, which rendered both so obnoxious to the Catholics that one of them was massacred on St. Bartholomew's day, 1572, and the other narrowly escaped.

Concerning the mistaken identity of these musicians, Bayle has cleared up that point with his usual accuracy; and proved from indisputable authority, that Le Jeune was living and in the highest public favour, even at court, though a Hugonot, many years after the fatal feast of St. Bartholomew, particularly in 1581, when the wonders which he is said to have performed by his musical art at the wedding of the duke de Joyeuse are recorded. The works of Claude le Jeune consisted chiefly of miscellaneous songs, and psalms; *de melanges, des chansons, des pseaumes*, of which he published many books. His "Melanges" consist of songs and motets, in French, Italian, and Latin. His songs are chiefly French, and in many parts like the madrigals of Italy. Of his psalms in simple counterparts of three and four parts, we have examined three several editions, printed in different forms and in different countries; and as far as counterpart is concerned we find them admirable. Few of the melodies, we believe, were of his invention, but were the productions of the first German reformers; they however went through more editions perhaps than any musical work since the invention of printing.

Claude, Clauda, or Claudius, in *Ancient Geography*, an island of the Cretan sea, mentioned by Ptolemy, and in the Acts of the Apostles, (ch. xxvii. 16.) and lying S. of Crete. In Pliny's time it had a city called Gaulos. This island is supposed to be the modern isle of Gozo

Claude, St., in *Geography*, a town of France, and principal place of a district in the department of Jura; the place contains 3579, and the canton 14,722 inhabitants; the territory comprehends 382½ kiliometres and 32 communes.

Claude, St., a town of France in the department of Charente, and chief place of a canton in the district of Confolens; the place contains 2008 and the canton 12,289 inhabitants; the territory includes 295 kiliometres and 17 communes.

CLAUDENDA *curia*. See Curia.

CLAUDENS *palpebras*, in *Anatomy*, a name given by Spigelius, and some others, to one of the muscles of the face, called by Albinus and Winslow, *musculus orbicularis palpebrarum*, and by others *sphincter palpebrarum*.

CLAUDER, Gabriel, in *Biography*, physician to the elector of Saxony and member of the Imperial Academy at Vienna, was born at Altenbourg, in the year 1633. After being instructed in the Greek and Latin languages, in which he is said to have made great proficiency, he was sent, at the age of eighteen, to Jena, to be initiated in the different branches of medicine, which he studied under the professors Rolfinck, Moebius, and Schenck. He then went to Leipsic, Holland, and England, conversing, in each place, with the most eminent of the professors. Returning by Leipsic, he took his degree of doctor in medicine in 1662. He was a frequent correspondent of the Acad. Nat. Curios. and furnished them with a great variety of observations, which appear in their collections. In a man who died after almost incessant vomiting, the stomach, omentum, and part of the duodenum, were found in the cavity of the thorax. One patient took thirty, and at length

 fifty

fifty grains of solid opium each day, and continued the practice eighteen months, without suffering any inconvenience. He gave the hyoscyamus in dysentery with success. For the titles and accounts of the remaining dissertations, see Haller's Bib. Med. His separate publications are "Dissertatio de Tinctura Universali, vulgo Lapis Philosophorum dicta," Altemb. 1678, 4to. "Methodus balsamandi Corpora humana, aliaque majora, sine Evisceratione et Sectione, hucusque solita." Altem. 1679, 4to. The preparation used by him was supposed to be similar to that employed by De Bils, of which he had heard (see the article BILS, DE, in Vol. iv. of the Cyclopædia,); it proved equally insufficient. "Dissertatio de Cinnabari nativa Hungarica, in majorem efficaciam fixata et exaltata." Jena, 1684, 4to. The cinnabar was exposed to the flame of a lamp for the space of eight or nine months; it was then exposed to other degrees of heat for about four months longer; at the end of this process it was supposed to have acquired a specific power over the lues venerea. In this also he was unsuccessful, and we only learn from it that he had an active mind, and was desirous of doing something beneficial to humanity, and which might transmit his name, with credit, to posterity. He also left "Praxeos Medicæ Monumenta generalia," which was published at Chemnitz, 1729, 8vo. He died Jan. 9, 1691. His nephew, Frederic William Clauder, succeeded him in his post of physician to the elector of Saxony. He was also elected member of the Imperial Academy, and, like his uncle, sent some observations which were published in the "Collectanea." Haller, Bib. Eloy. Dict. Hist.

CLAUDIA, in *Ancient Geography*, a town of Norica, according to Pliny; named Claudivium by Ptolemy. Cluverius supposes it to be Clausen in Bavaria, and Hardouin refers it to Clagenfurt in Carinthia.

CLAUDIA *Regio*, a country of Asia Minor, in the vicinity of the town of Miletus. Diod. Sic.

CLAUDIA *Via*, a Roman road, in Italy; commencing at the bridge Milvius and joining the Flaminian high-way.

CLAUDIÆ *Aquæ*, two fountains of Italy, in the neighbourhood of Rome. Suetonius.

CLAUDIAN, CLAUDIUS CLAUDIANUS, in *Biography*, an eminent Latin poet, flourished in the fourth century under the emperors Theodosius, and his sons Arcadius and Honorius. Like the epic bard of Greece, various cities have contended for the honour of having given him birth. It has been maintained by some that he was a native of Florence, by others, of Gaul, while a third party have supposed him to have been a Spaniard; but the most probable and best authenticated accounts, among which may perhaps be placed his own testimony, assert that he was born at or near Alexandria in Egypt. He was greatly in favour with the celebrated general Stilicho; and enjoyed all the benefit of the extensive patronage of that commander while he retained his influence and authority in the government of the empire. He was made a tribune and notary, and had, at one time, so highly ingratiated himself into public esteem, that the senate ordered a statue to be erected in honour of him, in the forum of Trajan, with an inscription expressive of their high opinion of his accomplishments and practical merit. Serena, the wife of Stilicho, procured for him, by her extensive interest, a most advantageous marriage with a wealthy lady of Africa. When his patron was put to death, Claudian considering that the favourites of a disgraced minister are generally objects of enmity or suspicion to his successful and triumphant adversaries, hastily quitted the court. Little is known of his subsequent history; but it has been supposed that he passed the remainder of his days in retirement; it does not appear, however, that he was deprived of any of his dignities. From some pieces which have been inserted by ignorant editors among his poems, it has been thought by some that he was a convert to Christianity; but there are the strongest reasons to prove that he was a polytheist and idolater to the last. Orosius, particularly, calls him "an obstinate pagan;" and his own works abound with passages which imply that he was a votary of the popular superstitions of Pagan Rome. Lardner, nevertheless, quotes him as bearing a remarkable testimony to the victory of the Christian emperor Theodosius in Gaul, and which was decided in his favour by a storm so extraordinary in its effects upon the army of his adversaries as to have been regarded even by Claudian himself as a proof of divine interposition.

Claudian justly holds a distinguished rank as a poet. During the decline of Roman literature, he alone has left to posterity, specimens of composition which may be regarded as worthy of the Augustan age, for the purity and classic elegance of their style and language. He is by many esteemed the poet who approached nearest to Virgil in the dignity and harmonious flow of his versification. Fabricius styles him "poeta floridus et amoenissimi ingenii." His poems, however, display great inequalities of genius; for although he sometimes astonishes by the boldest flights of imagination, and bears away his readers by the fire and animation of his language, he often flags in the midst of his finest passages, and, in his longer poems especially, generally falls off before he reaches the conclusion. His writings are numerous; the principal of his pieces are, a severe satire which he wrote against Ruffinus and Eutropius, who were the rivals of his patron Stilicho; his poems in honour of Honorius and of Stilicho; his "Rape of Proserpine," the commencement of an epic poem which he never finished; his "Idylliums and Epigrams." The most valuable editions of his works are those of Barthius and Heinsius; Delphin, Gesner, 1759; and Burman, 1760. Suidas, Fabricius, Tiraboschi, Tillemont.

CLAUDIANA, in *Ancient Geography*, a town of Asia, in Syria, near the Euphrates.

CLAUDIAS, a town of Asia, in Armenia Minor; supposed to be the same with Claudias, *Ara-Cloudieh*, in Comagene, on the right bank of the Euphrates, N.E. of Juliopolis, and S.S.E. of the place where the Euphrates crosses the Taurus.

CLAUDICATION, in *Surgery*. See LAMENESS.

CLAUDIO, LORRENESE, or CLAUDE LORRAINE, in *Biography*. See GALLIE.

CLAUDIOMERIUM, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the country of the Artabri.

CLAUDIOPOLIS, a town of Asia Minor in Bithynia, called also Bithynium by Dion Cassius and Ptolemy; it is placed on the river Sangar and named Bithynia by Pausanias.—Also, a town of Asia in Isauria, according to Ammianus Marcellinus, who says that the emperor Claudius sent thither a colony. It had been episcopal.—Also, an ancient town of Asia in the Honoriade, according to the book of the Authentics. It had been episcopal according to Hierocles, who distinguishes it from that of Isauria.—Also, an ancient town of Asia, in Cataonia, a country of Armenia Minor, according to Ptolemy. Pliny places it in Cappadocia. It was probably the same with the Claudiopolis of Isauria. These towns derived their names from Claudius Cæsar, son of Drusus, who established colonies in various parts of the empire.—Also, a town of Galatia, at a small distance from the river Halys. It was formerly called Adrapta. Ptolemy calls it the new Clodiopolis, or Neo-Clodiopolis.

Clodiopolis.—Alſo, a town of Armenia Minor, near the Euphrates, ſuppoſed to be the ſame with *Claudias*.

CLAUDIUS, Tiberius Claudius Drusus Cæsar, in *Biography*, the fifth of the emperors of Rome, was born at Lyons in Gaul, about ten years before the birth of Chriſt. He was the ſon of Nero Claudius Druſus, and Antonia; deſcended on his father's ſide from Livia, the wife of Auguſtus, and on that of his mother, from M. Antony and Octavia, the ſiſter of Auguſtus: he was alſo the nephew of Tiberius, the brother of Germanicus, and the uncle of his predeceſſor in the empire, Caligula. Having loſt his father while he was in his infancy, the care of his education was committed to a preceptor, of whoſe cruel treatment he afterwards loudly complained. Under the tuition of this pedagogue he made conſiderable proficiency in ſeveral branches of learning, and acquired a competent knowledge of the Greek language ſo as to be able to write and ſpeak it with facility; but being all his life time ſubjected to a great variety of bodily diſorders, his judgment and mental powers were ſo greatly impaired and enfeebled, that he was not deemed capable of undertaking any public truſt in the government of the empire. His relations in general rated his abilities very low; even his mother and ſiſter, from whom ſome tenderneſs at leaſt was due to his weakneſſes; and they were not ſparing of their ridicule and declarations of contempt whenever his name happened to become the ſubject of converſation. During the reigns of Auguſtus and Tiberius he was ſuffered to remain in the condition of a private citizen; but when his nephew Caligula obtained the imperial purple, he was dignified with the rank of ſenator, and made the colleague of the emperor in his firſt conſulſhip. During this period he occaſionally preſided inſtead of Caligula at the public games, and was frequently greeted by the acclamations of the aſſembly as the brother of their favourite Germanicus. He was, however, much more commonly the object of contempt than of public eſteem; the domeſtics whoſe duty it was to attend upon him as their maſter, treating him at their pleaſure with the groſſeſt indignities. After ſuffering ſuch various mortifications, in which his life was not unfrequently expoſed to imminent danger, a circumſtance, which to the thoughtleſs mind may bear the appearance of accident, diverted the courſe of events, and raiſed him to the throne of the Cæſars. At the time Caligula was aſſaſſinated, Claudius was in the palace, but was ſo terrified and alarmed at the event, that he retreated to an adjoining balcony, and concealed himſelf in the hangings of a doorway. A ſoldier, who was roaming for ſpoil, obſerving his feet, dragged him from his retreat, but had no ſooner recognized his perſon, than he fell on his knees, ſolicited his pardon, and addreſſed him under the title of emperor. This man, whoſe name was Gratus, was ſoon joined by other ſoldiers, equally diſpoſed, from their attachment to the memory of Germanicus, to ſerve his brother; they placed the terrified emperor in a chair, conveyed him to the camp full of conſternation and fears for his life, and lodged him within the ramparts for the night. On the following morning (January 25th, A.D 41. A.U. 794.), the ſoldiers formally eſtabliſhed him at the head of the empire, by ſwearing allegiance to him as their lawful ſovereign; for which, it is ſaid, he promiſed to reward them liberally at a future period. The ſenate, when they found themſelves delivered from the ſanguinary deſpotiſm of Caligula, made ſome attempts to reſtore the ancient conſtitution of the commonwealth; but not being ſufficiently prompt in their deciſions, nor cordial in their co-operation, they were obliged to abandon their ſcheme, and ſubmit to the governor whom the military had been pleaſed to inveſt with the inſignia of power. Claudius began his reign with ſeveral acts of lenity, moderation, and juſtice. He publiſhed a proclamation of pardon to all who had in any manner oppoſed his elevation to the throne, or who had been concerned in the late conſpiracy againſt Caligula, ſuch perſons only excepted as had been actually engaged in his aſſaſſination; and it has been thought that he was urged to the condemnation and puniſhment even of thoſe by apprehenſions that his own life was not ſecure againſt their daggers. The laws which were at that time in force concerning treaſon, he aboliſhed, as too tyrannical and ſevere, and releaſed ſuch perſons as had been impriſoned on account of them by Caligula and Tiberius; he aboliſhed ſeveral oppreſſive impoſts which had been extorted by thoſe emperors from the people; and whatever property they had unlawfully taken from their ſubjects, he reſtored to the parties themſelves, if alive, or elſe to their deſcendants. In all theſe proceedings he conducted himſelf with ſingular modeſty and propriety. He did not appear at all elated by the popularity which they acquired him, nor would he conſent to accept the honours which the ſenate had decreed him as a teſtimony of their attachment and gratitude. Theſe were, however, but the tranſient efforts of a character radically feeble and debaſed, too deficient in firmneſs and energy to preſerve an uniformity of virtue, or maintain a ſolid popularity, in a turbulent and licentious age. His natural imbecility of intellect, while it rendered his perſonal conduct in the government feeble and contradictory, made him an eaſy dupe and obſequious ſlave to the bolder ſpirit of his wife, Meſſalina, of infamous notoriety, and of his ambitious and daring freed-men and favourites, Pallas, Caliſtus, and Narciſſus. Their policy was to keep his mind in a ſtate of conſtant alarm, to inſpire him with diſtruſt and ſuſpicion of all who were obnoxious to themſelves, and whoſe rank or influence in the ſtate might render them formidable opponents to their ſchemes of aggrandiſement and blood; and, under feigned pretences of diſaffection and treaſonable deſigns, to obtain from him the imperial ſanction for their unbluſhing enormities of proſcription, baniſhment, and murder. It may be ſaid, that while he wore the purple, the ſceptre was in other hands; and of the many acts of his reign, ſmall indeed is the proportion of thoſe which can with hiſtorical propriety be attributed to the uncontrouled dictates of his own mind. At the inſtigation of the licentious and ſanguinary Meſſalina, Julia, the niece of the emperor, and other women of diſtinction, who were falſely accuſed, were put to death; and Seneca, among other of her victims, baniſhed to Corſica. To the ſame influence, ſupported by the power of her willing miniſters, Narciſſus and his fellow freed-men, we may alſo ſafely refer the frequent execution of Roman ſenators, and of Roman knights, to the almoſt incredible number of three hundred and upwards, who became the unfortunate objects of her ſuſpicion and vengeance. At length, however, ſhe fell a ſacrifice to the unreſtrained impulſes of her licentious paſſions. She became enamoured of Caius Silius, a young Roman of noble birth and remarkable beauty. In order the more ſecurely to carry on her adulterous connections, ſhe cauſed him to be divorced from his wife, whom Tacitus calls "a lady of elevated rank," and inveigled him into her toils by the flattering promiſes of royal favour, and by holding out no very equivocal hopes of future elevation to imperial honours.

It is, perhaps, ſcarcely poſſible to find, even in the annals of declining Rome, a greater monſter of depravity than this woman, or one whoſe character is blackened with darker ſhades of criminality. Inflamed by her guilty paſſion, ſhe broke through every reſtraint of decency; frequented the houſe of her paramour in the moſt open and undiſguiſed manner, loaded

ed

-ed him with the richest presents, and publicly treated him in every respect as if he had been her husband and the emperor of Rome. The historical student almost doubts the evidence of facts, when it is added respecting her, that, daring beyond all example in iniquity, she had the shameless effrontery to marry this object of her brutal lust. She availed herself of the absence of Claudius at Ostia, to put this final seal to her wickedness, and to stamp her character with indelible infamy. Claudius remained long a stranger to her practices and to his own disgrace, and would probably have become the victim of the adulterous parties, had not Narcissus, rather fearing their power than abhorring their guilt, taken measures to apprize him of his danger, and eventually to effect their downfall and punishment. So insensible was the dishonoured emperor of the stain which had been inflicted upon his character, that it is doubtful whether he would have punished the defilers of his bed, had he not been urged, and repeatedly impelled to it by Narcissus, who, availing himself of an involuntary consent extorted from him with great difficulty, dispatched a tribune to the gardens of Lucullus, where Messalina had retired in despair, to put her to death. Nothing can give a more degrading idea of the character of Claudius than the account which Tacitus gives of this transaction. He was enjoying the luxuries of his table when the intelligence was communicated to him of the death of the empress; he received it without emotion, and did not suffer her fate, interesting as it was in many important points of view, to interrupt his pleasures. He was alike insensible to the feelings which such an event might naturally have been supposed to awake in the breast of a husband, and to the lamentations of his children at the loss of their mother. After the downfall and death of Messalina, Agrippina, the niece of Claudius, artfully availed herself of the advantages of access to his person which her near relationship gave her, to ingratiate herself into favour with him, and ultimately so completely succeeded in her plan, as to induce him to take her for his wife. A vote to recommend, to legalize and justify this incestuous union, so contrary to the Roman customs, as well as revolting to human nature, was previously obtained from the senate, who pleaded for the marriage as an event which promised to be of the greatest benefit to the state. As Messalina had rendered herself unpopular by her various acts of tyranny, Agrippina thought it adviseable to reverse, as the first act of her power, one of the proceedings which had given most offence to reflecting men, by recalling Seneca, whom her predecessor had caused to be banished; but perhaps her real motive in this affair was to give Domitius, her son by a former marriage, the advantage of his instruction, in order to raise him to the empire, as she afterwards did, to the prejudice of Britannicus, the son and legitimate heir of Claudius. From the proceedings of the government, it soon appeared that Claudius had only exchanged one mistress for another. As he had formerly been the dupe and the slave of Messalina, so was he now the tool and the vassal of Agrippina. Her whole ambition was to obtain the future sovereignty for her own son, and to this all the efforts of her craft and power were directed. Whoever was considered as hostile to her views, was soon removed from the situation where he might have the means to embarrass her proceedings, and none were admitted to offices of trust and honour but such as were subservient to her will and devoted to her cause. As some of her measures, resulting from extreme anxiety, were prosecuted with too little disguise and precaution, Claudius was privately apprised of their dangerous and threatening nature. In the paroxysm of terror, which never failed to alarm him, when he had reason to suspect treasonable designs against his life, he gave vent to his feelings in expressions of threatening import, which soon reached the ears of Agrippina. She no sooner learned his sentiments than she fully apprehended her danger. She saw that strong measures must be pursued before her object could be secured, and that the utmost promptness was necessary in the execution of them. To rid herself therefore of every cause of alarm, and of every chance of opposition, she took an early opportunity of administering poison to him in a favourite luxury of his taste. This had the intended effect, and proved fatal to him, A. D. 54, in the 64th year of his age, after having worn the imperial purple 14 years.

When the imbecility of his character is considered, no personal military achievements of importance can be expected to have added glory to his reign. But though the throne of the Cæsars was occupied by a being scarcely human in respect to mental capacity, the empire was not without military commanders to support the dignity of the Roman name. In Germany, Corbulo and Galba led the Roman legions to victory and conquest; while Plautius carried the Roman eagle triumphantly through many of the fertile provinces of Britain. At the time this general was pursuing his conquests, Claudius himself, desirous of obtaing the nominal honours of a triumph, passed over into Britain, and after witnessing some of the successes of his troops returned to Rome, to decorate his brow with the honours which had been hardly earned by the valour of his generals and their brave followers. Plautius was succeeded by Ostorius, who prosecuted the successes of his predecessor, and vanquished the brave and noble Caractacus. Claudius, however, though he could hardly flatter himself with the hope of high distinctions as a military man, was ambitious of literary reputation. Several compositions of his in the Greek and Latin languages are mentioned by Roman writers; but he signalized himself principally by his attempt to improve the Roman alphabet. He added three letters to those already in use, which were adopted pretty generally during his reign; but his successors do not appear to have been convinced of their utility, as they were not used after his death. His reign did not, however, pass without some public works of national importance. The better to provide the city of Rome with grain from foreign markets in years of scarcity, he formed a port at Ostia, at the mouth of the Tiber. He cut a grand canal with the view of draining the water of the Fucine lake, and recovering the land which it inundated for the purposes of agriculture. This was an undertaking of astonishing difficulty, which employed for eleven years nearly thirty thousand labourers; it did not, however, fully succeed, nor produce a benefit at all adequate to the immense expence bestowed upon it. But perhaps Rome was most indebted to this emperor for completing an aqueduct of stupendous magnitude, which had been begun by Caius, by which the city was supplied with the delightful waters which issued from the springs of the neighbouring hills. The character of Claudius was a strange mixture of good and bad qualities. The former, however, lost their effect in his conduct from the want of energy and firmness of mind to act in conformity to their dictates; and the latter, operating with equal blindness and indiscrimination, led him, in the administration of the empire, to the most wanton acts of cruelty, and the most barbarous measures of tyranny and oppression. His puerile attempts to administer justice in person, seemed only to defeat the very end he aimed to secure, and to render him ridiculous in the eyes of an indignant public; and his impotent endeavours to crush the immediate objects of his suspicion and hatred, instead of effecting their destruction, most commonly recoiled with accumulated force against himself, and rendered him the object of vengeance

rather

rather than the dispenser of destruction and death. But it is useless to dwell upon a character which has nothing in it worthy of the notice of posterity. He died lamented by none,—despised by all; and was succeeded by Domitius, the son of Agrippina, who is better known under the name of Nero. Suetonius. Tacitus. Tillemont.

Claudius, M. Aurelius, (sometimes called Claudius II.) was a native of Illyricum, and most probably a person of mean and obscure parentage. He was early distinguished for his military talents, and, after having gained the approbation and confidence of the emperor, the senate and the people of Rome, was promoted by Decius to the chief command of the Illyrian frontier, and of the troops which were stationed in Thrace and the neighbouring provinces. At this period the barbarians of the north were frequent in their incursions into the Roman territories, and afforded the Roman legions full employment to repel their attacks. On the side of Illyricum Claudius had to contend with the Goths; and by his skill and bravery obtained a victory over them, for which the senate decreed him the honour of a statue. The emperor Gallienus viewed his success and popularity with a different eye; but, dreading a rupture with a man who, by his great services in supporting the tottering fabric of the state against those powerful enemies who were assailing its foundations, and who ultimately effected its ruin, was regarded with just esteem by all ranks of citizens, he thought it best to temporize, and to disguise his real feelings by rich and munificent presents, which were intended to lure the mind of Claudius to a belief that it was the sincere wish of the emperor to cultivate his friendship. Gallienus, during the siege of Milan, where Aureolus, an impostor, and his desperate followers, had shut themselves up, was treacherously killed by some of his own officers; and Claudius, though at the time absent on duty at another post, has not escaped suspicion of being privy to the conspiracy. Perhaps, however, his subsequent elevation is the only circumstance which can be said to give a colour of probability to so foul an imputation. It is said, that when Gallienus found that his wound was likely to prove mortal, he nominated Claudius his successor, and strongly recommended him to the choice of the soldiers and the senate. The consent of the latter was easily obtained, for he was already their favourite; and the concurrence of the former was secured without much difficulty by large promises of reward. Claudius was, therefore, invested with the imperial purple, A. D. 268, and as nearly as can be judged in the fifty-fourth year of his age. He prosecuted the siege of Milan with redoubled vigour, and soon compelled Aureolus to surrender at discretion, and submit to the fatal doom which the army adjudged to be his due. His unfortunate adversary was, however, executed contrary to his wishes. Claudius, on coming to the throne, found himself placed in a situation crowded with difficulties, and with dangers of the most threatening kind. The emperors whom he was called to succeed, abandoned to the debilitating luxuries and pleasures of the age, had neglected the discipline of the troops, and relaxed in the maintenance of that regular subordination which had in former times trained them up to be the conquerors and the masters of the world; and had by this means weakened the barriers of the empire, which were now every where assailed by the most formidable and determined enemies. The first care of Claudius was to correct, as far as circumstances would admit, the error of his predecessors; to controul the licentiousness of the military, and to impart to them the energy and bravery as well as the name of Roman soldiers. Having, in some measure, succeeded in his undertaking by the judicious use of his influence over them, he prepared to put their valour to the severest test. The Gothic nations on the shores of the Euxine had assembled a formidable armament near the Niester, where, from two to four thousand transports were prepared to convey them towards the Grecian provinces. After various vicissitudes, in which, from want of nautical skill, and from the unpropitiousness of the weather, they suffered very extensive losses, a body of them, said to amount to the almost incredible number of three hundred and twenty thousand, landed near mount Athos, and laid siege to the city of Thessalonica. Claudius, on the first intelligence of their invasion, marched with all possible expedition to check their progress, and avert the desolation with which they threatened the empire. While on his way, he addressed a letter to the senate, which is still extant, expressive of the great disadvantages under which he would have to combat his formidable adversaries, from his want of arms of almost every description, and, more than all, from the imbecile and pusillanimous spirit with which the depravity of the times had infected the legions which attended him. It displays, however, a brave, determined, and dignified courage in himself, by which he appeared prepared to contend for victory with unbending resolution, and to enjoy the honour of conquest, or to submit to defeat without despondency. He first engaged the Goths at Naissus, in Dardania. His troops, overpowered by numbers, began to give way; but a detachment, which had been purposely stationed in some of the defiles of the mountains, issued forth in the critical moment, attacked the enemy in the rear, inspired their countrymen with new courage, and ultimately caused the barbarian hordes to fly in disorder, and to leave behind them fifty thousand of their number dead upon the field of battle.

Claudius delayed not to prosecute the advantages he had almost unexpectedly obtained; but his progress was, nevertheless, an arduous struggle against the desperate efforts of a determined foe. The Goths rallied their troops; and, while they retreated towards Macedonia, resolutely contended for every inch of ground over which they had to pass. Their army was, however, at length destroyed, through the superior skill of Claudius, and his intimate acquaintance with the country; and his soldiers obtained a rich booty of cattle and slaves as the reward of their toils. The few that escaped the sword of the vast multitude which, but a short time before, had spread like locusts over the shores of Greece, took refuge in the precipitous retreats of mount Hæmus, where want, and the inclemency of winter, soon lessened their number, and completed their wretchedness. By this signal and splendid victory Claudius merited the highest reward from his countrymen. It was, indeed, scarcely possible to over-rate his services, since he contributed most essentially to support the falling greatness of the empire, and to save it from sinking at once beneath the power of enemies, who, like a mighty torrent, were rolling towards it, and threatening it with instant and complete desolation and ruin. He did not live, however, to enjoy the glories of the triumph, nor to receive the plaudit he had so well deserved. He fell a victim at Sirmium to the pestilence which had broken out among the Gothic fugitives, after a reign of two years, which, for its length, may vie in splendour with any that are recorded in the page of history. He was succeeded by Aurelian, one of his generals, who afterwards proved himself worthy of the partiality to which he owed his elevation. Crevier. Gibbon.

Claudius, Appius, a Sabine by birth, whose original name

name was Atta, or Aetius Claufus. He was a man of fome confequence in his own country, but conceiving himfelf to be ill ufed by a factious party who were endeavouring to ftir up a war againft the Romans, he removed (about A.U. 254, B.C. 500.) with a large body of his partizans to Rome, where he was well received, and admitted into the patrician order. On this occafion he changed his name to Appius Claudius, and became the founder of one of the moft illuftrious of the Roman families. He was elected conful with Publius Servilius A.U. 259. B.C. 495., and became the refolute opponent of the common people in their turbulent demands to be relieved from the operation of the laws then in force againft debtors. He withftood them with firmnefs and with fome feverity, and by that means gained the efteem and confidence of the fenate; while his colleague, who wanted his energy and decifion of character, by purfuing half meafures with them, forfeited the refpect of both parties. He afterwards fhewed the fame fpirit of hoftility to the plebeians, in his oppofition to the Agrarian law; and on all public occafions ftood forward the moft determined fupporter of the power and authority of the patricians. The imperfection of the hiftorical documents of this early age prevent our being able to ftate the time of his death. Livii Hift. lib. ii.

Claudius, Appius, was the fon of the preceding, and equally diftinguifhed for his fupercilious contempt of the plebeians, and his refolute hoftility to all the public meafures which originated with them. Volero, one of the tribunes of the people, propofed a new law for determining the election of their magiftrates, which went very much to reftrict the power which the patricians had before poffeffed on fuch occafions. The fenate, therefore, to maintain their former influence, obtained the confulfhip for Claudius (A.U. 283. B.C. 471), who they knew would not be wanting in exertions to fupport their caufe; and gave him for a colleague, Titus Quintius, a man of milder temper and more conciliatory difpofitions. Notwithftanding, however, all that Claudius could do, the law of Volero paffed, and he had the mortification to find himfelf defeated by men whom he defpifed. He vented his fpleen in invectives againft the fenate, and attributed his failure to their cowardice in withholding from him the affiftance and fupport it was in their power to have rendered him. While thefe diffentions were embroiling the citizens of Rome in fevere contefts againft each other, their attention was called to the hoftile menaces of external foes. The Æquans and Volfcians had availed themfelves of thefe divifions to take the field, and had invaded the Roman territories. Quintius was difpatched againft the Æquans, and Claudius againft the Volfcians. He was no fooner invefted with the command, than he gave full vent to the ill-will and hatred which burned in his breaft, by treating the foldiers with the moft unjuftifiable harfhnefs and feverity; and his conduct had the natural effect of rendering more inveterate the averfion in which he was before held by them. This he foon had a painful opportunity of knowing; for when his troops had drawn near the enemy, and it became neceffary for him to lead them to battle, they threw down their arms in difguft, and fled with the utmoft precipitation towards the city, difgracefully abandoning their ftandards to an enemy whom they might eafily have vanquifhed. For this defertion of duty, and flagrant violation of difcipline and fubordination, they were however afterwards punifhed by their incenfed general; fome he beheaded, others he caufed to be beaten with rods, and the remainder he punifhed by decimating them, and inflicting the penalty on every tenth man, who was felected by lot. In the year following frefh contefts arofe between Claudius and the people. Having been particularly active in his oppofition to the Agrarian law, a profecution was inftituted againft him by the tribunes, and he was compelled to appear before the tribunal of his determined foes. He held their perfecution of him however in fovereign contempt. He refufed to put on the humiliating drefs which it was ufual for an accufed perfon to wear during his trial, and unawed by the dangers which threatened him, he pleaded his caufe with the fame boldnefs of demeanour, the fame unbending ftubbornnefs of fpirit, and the fame bitternefs and violence of expreffion, which characterized his proceedings and harangues when he was armed with the confular authority; and it is faid by his hiftorian, Livy, "that the people confeffed themfelves more awed by the culprit than they had been by the conful." The impreffion which his firmnefs made on his accufers and judges caufed the trial to be adjourned to a future day; but before that day arrived, he was feized by a diforder which foon terminated in his death. He was buried with honours fuitable to his rank and character; and in liftening to the encomiums pronounced over his grave, the multitudes who attended, and who but a fhort time before were bent upon his deftruction, convinced of their juftnefs, forgot their enmity in the admiration of his virtues. Livii Hift. lib. ii.

Claudius, Appius, the *Decemvir*, has been thought to be the fon of the laft-mentioned of the fame name, and was the firft perfon elected to that office (A.U. 303. B.C. 451.) on the change of the conftitution of the commonwealth. He inherited from his anceftors all that averfion to the common people, for which they had been remarkable; but being ambitious of popular honours, he changed his tone, and became, before his election to the decemvirate, their warm advocate and friend. His favour with the common people enabled him to procure the office a fecond time, and to choofe, as his colleagues, men of the moft worthlefs characters, who were not likely to thwart him in any of his fchemes, whatever might be their iniquity. With the concurrence of this faction, he ruled the commonwealth with a rod of iron, and contrived, under various pretences, to extend the period of his office beyond the year, the regular term of its duration; and from the numerous partizans which he had acquired among the plebeians, and the young and diffipated part of the nobility, would probably have refifted with fuccefs every attempt to effect his downfall, or to control his power, had not a circumftance happened which at once laid bare the bafe iniquity of his character, and roufed the generous indignation of an infulted people. During the abfence of the other decemvirs in the army, and when, according to the laws, he poffeffed fupreme power, he became enamoured of a young and beautiful woman, of the name of Virginia, whofe father, Virginius, was a centurion in the army. Having in vain practifed every infidious art, and tried every vile expedient to fubdue her virtue, he determined upon a device as daring as it was abominable to gratify his luft. He inftructed one of his creatures, Marcus Claudius, to claim her as his flave, who had been clandeftinely taken from him, and at all events to obtain poffeffion of her perfon, and detain her in cuftody until he, as fupreme judge, fhould think proper to decide the fuit. The abfence of her father on duty with the army, left him no room to doubt but by this means his purpofe might be fecured. According to this fcheme, Marcus embraced an early opportunity, and feized the devoted girl in the public forum; but his conduct exciting the indignation of the populace, who were not inclined to credit his tale, or acknowledge his claim, he found it moft prudent not to ufe violence, but to fummon her before the tribunal of Claudius, where he well knew what fentence to anticipate. Claudius, that his defigns might be in fome meafure difguifed, confented to put off his decision on the case till the morrow, to give time for her father to attend in her behalf; but, at the same time, to accomplish his purpose, he ordered that she should in the interim remain under the care of Marcus. On passing this decree, Icilius, a young man to whom she had been betrothed, alarmed at the danger which threatened the object of his affection, addressed Claudius in the bitterest terms of reproach, exposed his evil intentions, and so wrought upon the feelings of the populace, that the decemvir found himself reluctantly obliged to put off the execution of his design one day longer. To this, however, he submitted the more readily, because he did not think Virginius would be able to reach the city time enough to prevent the decree he meant to pass. But Icilius was too deeply interested in the event, to lose his cause through procrastination. He dispatched messengers to the camp even before Appius had quitted the judgment seat, and early on the morrow the anxious father was in the city. He proceeded to the forum, attended by his daughter, and several matrons, all clothed in mourning, to denote their distress; and on his way interested all men in his behalf, by the greatness of his affliction, and the danger which threatened his child. Claudius was already in waiting, and the claimant no sooner began to plead, than he interrupted him, and peremptorily decreed, that Virginia should be held in slavery, until he should finally decide her case. At this dreadful sentence every heart was petrified with horror; but Claudius, who alone beheld unmoved the agonizing spectacle, commanded the armed men with whom he had crowded the forum, to disperse the populace, who had closed round Virginius to support him. They retired, however, of their own accord; and the distressed father beheld himself deserted and forsaken, hopeless of assistance to protect his daughter from violence and from shame. Suppressing for a moment the tumultuous feelings of indignation which burned within him, he addressed Claudius in supplicating tones, praying permission to withdraw a little to make some inquiries of Virginia's nurse on the subject in dispute. He accordingly retired a short way towards the butchers' sheds, and, bursting with grief and despair, seized a knife and plunged it into his daughter's heart. "Thus, my Virginia," said he, "the only way in my power, do I secure thy freedom!" Then, turning to Claudius, "Appius," he exclaimed, "with this blood I devote thine head to destruction!" He then rushed from the crowd in desperation, clearing his way with the knife, which he still held in his hand. Icilius caught up the body of his espoused bride, and held it up to the view of the astonished multitude, and, by his pathetic expostulation, fired them with honest indignation and abhorrence of the monster who had been the real cause of the dreadful deed. Virginius had now reached the camp, and interested the great body of his brethren in arms in his distress. They unanimously agreed to avenge his wrongs, and instantly marched in a body to Rome. They demanded that the power of the decemviri, which they had so grossly abused, should be abolished; and the senate, dreading farther mischief, thought proper to comply. The old constitution being established, Virginius instituted a prosecution against Claudius for malversation, and caused him to be committed to prison, where, unable to bear the mortifications of his situation, and the disgrace which had overtaken him, he put a period to his existence. Livii Hist. lib. iii.

Claudius, Appius, commonly called *Cæcus*, or the Blind, was a descendant of the preceding, and much esteemed for his abilities, and for the public works completed under his care and direction. He is mentioned as being censor, A.U. 442. B.C. 312. with Caius Plautius for his colleague. Caius, disgusted with some proceedings regarding the choice of senators, resigned his office, and Claudius undertook its duties alone. He has perpetuated his memory by the great road which he caused to be made from Rome to Capua, a distance of 140 miles; and also by an aqueduct which was finished in his censorship, and which brought a plentiful supply of water 7 miles to Rome. (See Appian Aquæduct, and Appian Way.) He introduced an innovation into the order of the priests employed at the altar of Hercules, which gave great offence, by taking it from the Potitian family, who claimed it as their hereditary right, and consigning it to persons of meaner birth, and even to emancipated slaves. The abhorrence in which this transaction was viewed by the Romans, may be estimated by the language in which it is spoken of by Livy, who gravely states, that it was followed by very fatal consequences to the descendants of the Potitian family, and attributes to the wrath of the gods on the occasion the blindness with which Claudius was afflicted in his old age. In the year of Rome 446, B.C. 308, he was created consul, with Lucius Volumnius for his colleague, and was elected to that office a second time, with the same assistant, A.U. 456, B.C. 298. Soon after this election he was sent towards Etruria, to meet the combined armies of the Samnites and Etruscans, who threatened the Roman frontier. His engagements with them were a series of successive disasters, in which he lost his credit with his troops for military skill. Claudius was so greatly mortified at his defeats, that it was with the greatest reluctance he would seem to admit his inadequacy to combat the enemy, by admitting his colleague to bring in his forces to his assistance. When, however, he had submitted to this, and the armies were again engaged, he is said to have displayed the highest degree of personal bravery, and to have contributed very greatly to the successful issue of the engagement. The time of his death is not mentioned. Livii Hist. lib. ix. x.

Claudius is a name common to several other persons who are occasionally mentioned in the Roman history; but none of them are of sufficient importance to demand particular biographical notice in a work of this nature.

Claudius, in *Ancient Geography*. See Claude.

Claudius *Mons*, a range of mountains in Pannonia, which separated the territory of the Taurisci from that of the Scordisii. Pliny.

CLAVE, in *Block-Making*, a stool 14 inches high, made of elm, and supported by 4 legs; the top 6 feet long, 2 or 3 feet wide, and 8 inches thick at each end, and only 4 inches thick in the middle, in which the shells are set up with wedges for making the sheave-holes.

CLAVECIN, Fr. in *Music*, a harpsichord.

Clavecin *oculaire*, an ocular harpsichord. Father Castel, an ingenious and whimsical Jesuit, who was a geometrician and a great mechanic, passionately fond of music, finding in sir Isaac Newton's "Optics," that he compared the seven prismatic colours to the septenary or seven notes that lead to the octave in music, imagined it possible to excite the same sensations of pleasure to the eye by the melody and harmony of colours, as the common harpsichord produces to the ear by a series or combination of sounds.

He supposed that there was in nature a primitive and fundamental sound, and called that sound C; and that there was likewise in nature a principal and original colour, or key-note, among colours, which was the base and fundamental of all other colours, and that this was the primitive colour *blue*. And further, as there are in music three tones or essential sounds dependent on the primitive sound C, which compose the perfect or common chord C E G, or 8th, 10th, and

and 12th of the fundamental C; there are likewise three original colours dependent on *blue*, that are not compounded of any other colours, but are distinct and original: these are *blue*, *yellow*, and *red*. Blue is the key-note, red the 5th, and yellow the 3d or 10th.

There are in music five tones, and two semi-tones, C D E G A, and F B. There are likewise five primitive whole colours, *blue*, *green*, *yellow*, *red*, and *violet*, and two semitonic colours, *orange* and *purple*. The scale of music is therefore C D E F G A B, and the scale of colours, *blue*, *green*, *yellow*, *orange*, *red*, *indigo*, and *violet*; and as the whole tones in music are divided into half notes by flats and sharps, so the colours may be shaded off by the neighbouring colours, and rendered *demi blue*, *demi-yellow*, &c. going through the whole musical system, and composing colours upon the original septenary to suit all kinds of modulation.

It was so early as the year 1725, that Pere Castel announced his idea of an ocular harpsichord, and wrote an ingenious paper or memoire on the subject, in the "Journal des Savans," to which he long contributed; Diderot likewise drew up a description of the new instrument, and the celebrated German musician, Tilemann of Hamburgh, undertook to compose for it. A pamphlet on the subject was published in London about the year 1750, preparatory to an exhibition, and great expectations were raised in the credulous all over Europe.

Pere Castel in his youth chiefly attached himself to geometry, and published many tracts that were esteemed for their originality. His style was lively, free, natural, simple, and sentimentally energetic; but without method, and so visionary and whimsical, that he often touched and affected his readers at the same time that he made them laugh; and it was by this means that he amused and persuaded. His project of a *clavecin oculaire*, upon trial, was found ridiculous and impracticable, and was soon forgotten. He died in the year 1757, at the age of 68; and in 1763 there was published a collection of the bons mots, sallies, and singularities of Pere Castel.

CLAVELLATI CINERES. See CINERES.

CLAVENNA, in *Ancient Geography*, a town which belonged to the Helvetians, placed by the Itinerary of Antonine 10 miles from Larius lacus, or the lake of Como.

CLAVERACK, in *Geography*, a post town of America, in the state of New York and county of Columbia, pleasantly situated on a large plain, about 2½ miles east of Hudson city, near a creek of the same name. It contains about 60 houses, a Dutch church, a court-house, and a gaol. By the census of 1791, the township contained 3262 inhabitants, including 320 slaves. By the state census of 1796, it had 512 electors. It is distant 231 miles from Philadelphia.

CLAVES *insulæ*, a term used in the Isle of Man, where all ambiguous and weighty cases are referred to twelve persons, whom they call *claves insulæ*, i. e. *the keys of the island*.

CLAVICHORD, in *Music*, a keyed instrument, long known, and still much used in Germany. Its form is that of a small piano forte; it has no quills, jacks, or hammers. The strings are all muffled with slips of red cloth, and the tone is produced by little brass wedges, placed at the ends of the keys, which, when put down, press against the middle of the strings, acting as a bridge to each. When this instrument is touched by a great master, it is capable of great expression, though of a melancholy kind, something like the effect of the old close-shake on the violin. We had in 1772, the extreme pleasure of hearing the incomparable Emanuel Bach touch his favourite clavichord at Hamburgh; when he threw away such thoughts and execution in his *toccate* or preludes, as alone would have set up a young professor, and have established the character of a great musician.

In pathetic and slow passages on this instrument, whenever he had a long note to colour, he absolutely produced the effect of a cry of sorrow and complaint, such as could only be effected on the clavichord, and perhaps by himself.

The antiquity of this keyed instrument in Germany is very great among modern musical inventions; as there is a description and a representation of it cut in wood, in the Latin "Musurgia" of Ottomarus Luscinius, printed at Strasburg in 1536. But we find mention made of it, as a common instrument, in England, under the name of *clarichord*, by Taverner, still more early.

CLAVICITHERIUM. See CITOLE.

CLAVICLE, *Clavicula*, in *Anatomy*, one of the bones of the shoulder, connecting the acromion process of the scapula with the first bone of the sternum. See SKELETON.

CLAVICLE, *Fracture and Dislocation of*. See FRACTURE and DISLOCATION.

CLAVICULUS, in *Botany*, an old term for a tendril. See CIRRUS. Linnæus has still retained it in the name of *fumaria claviculata*, a plant whose leaf-stalks end in branched cirri; while he has called a neighbouring species, *capreolata*, the leaf-stalks of which themselves perform the same office, without any such branching terminations. This is an essential difference between the two species, which their names do not indicate.

CLAVICYMBALUM, in *Antiquity*, a musical instrument with thirty strings, in a perpendicular situation.

Modern writers apply the name to our harpsichords.

CLAVIER, *French*, implies, in *Music*, what we mean by the complete set of keys on the organ, harpsichord, pianoforte, virginal, clavichord, and spinet. When it is said of a performer on any of these instruments, *qu'il sait bien son clavier*, it implies that he has a good method of fingering, understands modulation, and has a neat and clean execution: as we say in England of a great player on the violin, that he knows the finger-board well.

CLAVIJA, in *Botany*, Bosc. Nouv. Dict. Flor. Peruv. Pl. 30. Class and order, *polygamia diœcia*.

Gen. Ch. *Cal.* five-leaved; leaves nearly round. *Cor.* wheel-shaped; mouth closed with five oblong projections; border five-cleft; segments almost round. In the male flower, tube membranous, ten-toothed, covering the abortive germ. *Stam.* five. In the female, tube none. *Stam.* five, barren. *Pist.* Germ superior, egg-shaped; stigma sessile, umbilicated. *Peric.* Berry globular, one-celled. *Seed* solitary, uniform, very hard, enveloped in the pulp, and seated on a fleshy receptacle. The hermaphrodite and male flowers are on different plants. Four species, all shrubs, are found in Peru. Bosc.

CLAVIOL, a musical instrument, said in the *True Briton*, August 9 1802, to be constructed by a Mr. Hawkins of New York. By the description in this paper, it seems much to resemble the lyrichord of Plinius, that was exhibited for two or three years in the middle of the last century; the tones of which were produced by wheels resined, which in their revolution acted as so many fiddle bows; the strings being brought into contact with the wheel by the pressure of the fingers on the key. One peculiarity in the lyrichord was, that the strings were tuned by weights. The bases were very fine, but the treble screamed intolerably. Plinius was a German, and the first who attempted to make large pianofortes in England.

The instrument called a *claviol* by Mr. Hawkins, "produces its effects from bowel strings, by a refined horse-hair bow, and is played with finger keys, like the harpsichord. The tones of this instrument are stated to possess the sweetness of the armonica, the richness of the violin, and the

grandeur

grandeur of the organ." We have never heard or feen this inftrument, and have not difcovered that any one has been fent to England; and only give this account of it as an advertifement. If its perfections are not exaggerated its invention would be a valuable difcovery.

CLAVIS, a Latin word, fometimes ufed in Englifh writers for a key.

CLAVIUS, Christopher, in *Biography*, a German Jefuit, was born at Bamberg, in Germany, in 1537, and became a very ftudious mathematician, and a voluminous writer. His works containing a complete courfe of mathematics, and confifting chiefly of elementary treatifes and commentaries on Euclid and others, without any original inventions, amount to five large folio volumes. Pope Gregory fent for him to Rome for the purpofe of affifting other learned perfons in the reformation of the calendar; and he afterwards engaged in the defence of it againft Scaliger, Vieta, and others, by whom it was attacked. He died at Rome, Feb. 6th, 1612, at the age of 75 years.

CLAVO, in *Geography*, a town of Corfica; 8 miles E.S.E. of Ajaccio.

CLAUS, a town of Germany, in the county of Bregentz; one mile N.N.E. of Bregentz.

CLAUSE, an article, or particular ftipulation in a contract; a charge or condition in a teftament, &c.

We fay, a *derogatory claufe*, *penal claufe*, *faving claufe*, *codicillary claufe*, &c.

CLAUSEN, in *Geography*, a town of Germany, in the Tyrolefe; 6 miles S.W. of Brixen.—Alfo, a town of Germany, in the circle of the Lower Rhine, and electorate of Treves; 5 miles S. of Wittick.

CLAUSENA, in *Botany*, Lam. Encyc. Juff. 430. Burm. Fl. Ind. 87. Clafs and order, *octandria monogynia*. Nat. ord. *Uncertain*, Juff.

Gen. Ch. *Cal.* one-leafed, fhort, rather flat, four-toothed. *Cor.* Petals four, round, feffile. *Stam.* Filaments eight, fhorter than the corolla, awl-fhaped, thickened, and hollow at the bafe; anthers round, verfatile. *Pift.* Germ fuperior, roundifh; ftyle cylindrical, fhorter than the ftamens; ftigma fimple.

Sp. C. *excavata*, Lam. Ill. Pl. 310. A fhrub. Leaves alternate, winged; leaflets numerous, petioled, oval-oblong, flightly crenulate, pubefcent. *Flowers* in a panicled raceme. *Fruit* unknown. A native of the ifland of Java.

CLAUSENBURG. See Colosoar.

CLAUSENTUM, in *Ancient Geography*, a town of Albion or England, marked in the Itinerary of Antonine, on the route from Regnum to Londinium, between Regnum and Venta Belgarum, 20 miles from the former, and 10 from the latter. It is fuppofed to have been Old Southampton. Dion Caffius fays, that this town had been celebrated before the reign of Claudius, and that it had been the refidence of Dunobelin.

CLAUSIT *extremum diem*. See Diem.

CLAUSTHAL, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Grubenhagen, containing 800 houfes, 2 churches, an houfe of orphans, a public fchool, a fmall garrifon, and a mint for coining money, and having near it filver mines; 15 miles S. of Goflar.

CLAUSTRAL *Prior*. See Prior.

CLAUSULA, in *Ancient Geography*, a river of Illyria, according to Livy, who fays that it watered the town of Scodra, on the eaftern fide.

CLAUSUM *fregit*, in *Law*, an action of trefpafs; thus called, becaufe the writ demands the perfon fummoned to anfwer to *quare claufum fregit*, of the plaintiff, why he committed fuch a trefpafs? See Capias.

CLAUSZ, in *Geography*, a town of Germany, in the archduchy of Auftria, 177 miles S.S.W. of Steyr.

CLAUSZNITZ, a town of Germany, in the circle of Upper Saxony, and territory of Erzgebirg; 14 miles S.S.E. of Freyberg.

CLAUTINATII, in *Ancient Geography*, one of the moft turbulent people of Vindelicia, according to Strabo. They are fuppofed to have occupied both banks of the Inn, near its junction with the Danube.

CLAVUM *Veneris*, in *Botany*, a name given by fome authors to the *water-lily*, or *nymphæa*.

CLAVUS, in *Antiquity*, a band, or fillet of purple, worn on the breaft by the Roman fenators and knights, more or lefs broad, according to the dignity of the perfon; from the proportions of which arofe the difference of *tunica anguftíclavia*, and *laticlavia*. See Tunica. This ornament, according to fome, was called *clavus*, *nail*, as being ftudded with little round plates of gold, or filver, like the heads of nails. Cantelius maintains, that the clavus confifted of a kind of purple flowers, fewed upon the ftuff; or interwoven with it. Others will have them to be the buttons or clafps by which the tunic was held together. Some again fuppofe that the latus clavus was nothing but a tunic bordered with purple. Scaliger is of opinion, that the clavi did not belong to the veft, but hung down from the neck, like chains and ornaments of that nature. Rubenius maintains, that the clavi were merely purple lines or ftreaks in the middle of the garment; and that they did not receive the name of clavi in allufion to the heads of nails, to which, as he thinks, they bore no refemblance, but that they were fo called from their being of a different colour from the reft of the garment; for the Romans, he fays, ufed to inlay their cups, and other precious utenfils, with ftuds of gold, or other ornamental materials. Thefe, from their likenefs to nail-heads, they called in general clavi. Hence it was natural to ufe the fame word for denoting thefe lines of purple, or other colours, which were different from the reft of the garment, as thofe clavi were of a different colour and figure from the veffels which they adorned. M. Dacier (in Horat. l. ii. fat. 5) fays, that the clavi were purple galoons, with which they bordered the fore-part of the tunic, on both fides, in a place where it came together. The broad galoons, he fays, made the laticlavium, and the narrow the anguiticlavium. As to the name of clavi, he thinks the ancients gave it to any thing that was made with a defign to be put upon another.

Clavus *annalis*. So rude and illiterate were the Romans towards the rife of their ftate, that the driving or fixing of a nail was the only method they had of keeping a regifter of time; for which reafon it was called *clavus annalis*. There was an ancient law, ordaining the chief prætor to fix a nail every year on the ides of September; it was driven into the right fide of the temple of Jupiter Opt. Max. towards Minerva's temple.

This cuftom of keeping an account of time, by means of fixing nails, was not peculiar to the Romans, for the Etrurians likewife ufed to drive nails into the temple of their goddefs Nortia, with the fame view; and from them it is faid to have paffed to Rome. Liv. lib. vii. cap. 3. We learn alfo from Livy (l. viii. c. 18.) that the Romans recurred to the ceremony of driving a nail into the temple in order to ftop the progrefs of a plague that raged at Rome A.U.C. 389. B.C. 365. The fame ceremony was again employed about thirty years after, by way of remedy againft a ftrange alienation of mind, which was confidered as the caufe of the multiplication of crimes in the city.

Clavus, in *Medicine*, See Cephalalgia.

Clavus *hyftericus*, a term introduced by Sydenham to denote a fevere pain of the head, which is peculiar to

 hyfterical

hysterical women. The pain is circumscribed, and is said to resemble the sensation, which a nail driven into the head might be supposed to occasion; hence the term *clavus*, a *nail*, was adopted. The cure of this species of head-ache, must depend upon the removal or palliation of the original disease, *hysteria*, of which it is a symptom. See HYSTERIA. See also CEPHALALGIA.

CLAVUS, in *Surgery*, See CORN.

CLAWEDOK, in *Geography*, a river of North Wales in the county of Denbigh, which runs into the Clwyd, four miles N. of Ruthyn.

CLAWING, or CLAWING-*off*, in *Sea language*, signifies the act of *beating* or turning to windward from a lee-shore, so as to escape the danger of shipwreck.

CLAWS, among *Zoologists*, denote the sharp pointed nails, with which the feet of certain quadrupeds and birds are furnished.

CLAWS, *Elks'*. See ELK.

CLAWS is also used for a close or small measure of land.

CLAY. In common language, any earth which possesses sufficient ductility when kneaded up with water to be fashioned like paste by the hand, or the potter's lathe, is called a *clay*. In *Mineralogy*, however, the term has a somewhat more extended application, comprehending not only the proper ductile clays, but certain other mineral substances which bear a strong analogy to them. They may be conveniently arranged under the five following sub-species.

1. Subsp. *Pure clay.—Reinethon Erde*, Germ.—*Lac Lunæ* of some authors.

Its colour is snow-white or yellowish-white. It occurs in small kidney-shaped pieces. It is without lustre; its fracture is fine earthy; it is opake; stains the fingers slightly; adheres feebly to the tongue; is fine but meagre to the touch; is very light, soft, and easily frangible. Its component parts, according to a recent analysis by Fourcroy, are,

45	alumine
24	sulphated lime
27	water
4	lime and silex.
100	

It has hitherto been found only at Halle in Saxony, where it occurs very near the surface, and accompanied by gypsum.

2. Subsp. *Porcelain clay.—Porzellauerde*, Germ.

Its colour is reddish-white, passing to yellowish and greyish-white. It occurs in mass and disseminated. It stains the fingers; is for the most part slightly coherent, passing into dusty; is fine but meagre to the touch; slightly adheres to the tongue, and is but of little specific gravity.

A specimen, analysed by Vauquelin, afforded the following result:

55	silex
27	alumine
0.5	oxyd of iron
2	lime
14	water
98.5	

When perfectly pure, it is nearly, if not entirely, fusible in the greatest heat of a porcelain furnace.

It forms beds in geiss, and not unfrequently occurs in granite, occupying the place of the felspar: indeed, it may readily be traced through various states of induration into true felspar; hence it has been considered by some as decomposed felspar, and by others as unformed or imperfect felspar.

The clay employed in the manufacture of the Berlin porcelain, is procured from the district of Magdeburg: the best French porcelain clay (the subject of the above analysis) is dug near Limoges; and the best English porcelain clay is procured from Cornwall: this latter is naturally mixed with quartz and mica, forming a granite, from both of which it is separated by washing.

3. Subsp. *Common clay.—Potter's clay.—Pipe clay.*

Its colour is very various; when greyish-white it is called *pipe clay*; it also occurs greenish-grey, passing into verdegris-green; smoke-grey, passing into yellowish-brown; reddish-brown and brownish-red; or, lastly, bluish-grey, passing into blackish-blue. It occurs massive, or fine slaty, forming veins or beds; these latter, often of great extent and thickness. Its fracture is earthy, passing into uneven or imperfectly conchoidal. It is generally smooth, and somewhat unctuous to the touch; adheres pretty strongly to the tongue, is soft and easily frangible.

When in veins, it generally occurs in primitive mountains, accompanying metallic ores; when in beds, it is usually found in alluvial land, covered by or resting on gravel.

It consists essentially of alumine and silex, but generally contains, besides, a variable proportion of oxyd of iron. Carbonated lime, too, is by no means an unfrequent ingredient, and when this abounds, the clay passes into marl. See MARL.

4. Subsp. *Indurated clay.—Clay-stone.*

Its colours are greenish-grey, bluish, ash, smoke, and pearl-grey, or brownish-red. It occurs in mass; is opake and without lustre. Its fracture is fine grained earthy, passing into slaty, splintering, and imperfectly conchoidal. It adheres but slightly to the tongue; is soft and easily frangible.

When put into water, it falls to pieces by degrees, but even then possesses very little ductility. It occurs in rock masses, in veins and beds, and forms the basis of clay porphyry. It passes, on the one hand, into potter's clay, and, on the other, into jasper.

5. Subsp. *Shale.*

Its colour is smoke-grey, yellowish, ash, or bluish-grey, or greyish black. It occurs in mass. It is dull, but when mixed with mica is glimmering. Its fracture is slaty, approaching sometimes to earthy. It is opake, soft, and easily frangible; it is meagre to the touch, adheres slightly to the tongue. Sp. gr. about 2.6.

It occurs in the independent coal formation, also in the most recent floetz trap and alluvial formations.

It generally breaks down when put into water, and by exposure to the weather it decomposes into a very unctuous and tenacious clay.

Of the above sub-species, the first, on account of its rarity, is made no use of. The second is the basis of the European porcelains, for which it is well adapted, on account of its difficult fusibility, and its hardness and compactness of texture when baked; it is even less fusible than felspar, from the decomposition of which, in particular cases, it certainly originates: but felspar contains a very notable proportion of pot-ash, which disappears during its decomposition, being probably washed away; and to this, no doubt, is owing the greater infusibility of the clay.

The method of ascertaining the goodness of porcelain clay is to knead it into a mass with water, and after having dried it very gradually and thoroughly, to expose it to a full white heat in a muffle; if, after being thus baked, its colour is a pure white, if its texture is compact and porcellanous, and it exhibits no signs of fusion, it may be considered as of the very best quality: but as it generally contains a variable proportion of iron, so its colour will exhibit more or less of a reddish-yellow tinge; and as this prevails, so the value of the clay will be materially impaired. A slight ashery tinge may

may be got rid of in the manufacture, by the addition of a little smalt; but the ware thus acquires a bluish tinge, which, though not very perceptible alone, is sufficiently obvious when compared with porcelain made of pure unsophisticated clay.

The common clays, or those that belong to the third subspecies, may be divided, with regard to their utility, into the three classes of unctuous, meagre, and calcareous.

The unctuous contains, in general, more alumine than the meagre, and the siliceous ingredient is in finer grains: when burnt, it adheres strongly to the tongue, but its texture is not visibly porous. When containing little or no oxyd of iron, it burns to a very good white colour, and is very infusible; pipes are made of it, and it forms the basis of the white Staffordshire ware. If it contains oxyd of iron, or pyrites, sufficient to colour it red when baked (as is usually the case), it becomes much more fusible, and can only be employed in manufacturing the coarser kinds of pottery.

Meagre clay is such as when dry does not take a polish from rubbing it with the nail: it feels gritty between the teeth, and the sand which it contains is in visible grains. When burnt without addition, it has a coarse granular texture, and is employed in the manufacture of bricks and tiles.

Calcareous clay effervesces with acids, is unctuous to the touch, and always contains iron enough to give it a red colour when baked. It is much more fusible than any of the preceding, and is only employed in brick-making: by judicious burning it may be made to assume a semi-vitreous texture, and bricks thus made are very durable.

Any of the unctuous or meagre clays, that are very infusible and contain but little iron, may be employed in making crucibles, and other similar chemical vessels, that are required to stand a powerful heat.

Clay, in *Agriculture*, a soft, earthy substance, of an unctuous and tenacious quality, and which is found in a native state in different situations. It has been remarked by Dr. Fordyce, to form a tenacious mass when mixed with water, which hardens upon drying, and does not diffuse so readily in water again as sand; and that if a mass of it be heated red hot, it becomes hard, and burns to a brick, resembling crystalline earth in its properties. It is also found that soap-earth agrees in its properties with clay, of which it is a species, only it is much more diffusible in water, separates from it with greater difficulty, is of a smoother texture, and has finer particles. It is a substance that by culture becomes more diffusible in water. The earth or soil consists chiefly of strata of substances, in which the clay and crystalline earth are sometimes found pure, but more commonly there is a mixture of the two; and it is seldomer that pure clay is found than pure sand. It has been remarked by Lord Dundonald, that this kind of matter forms not only a large portion of the surface-soil of most countries, but it is also found in the mineral strata to an immense depth; that argillaceous matter, or clay, is no where found pure, but is more or less adulterated with other earths, and with different materials, such as mineral, vegetable, and animal substances. And that the purest clay contains upwards of sixty per cent. of siliceous matter, or sand.

It is the earth most retentive of moisture, by which it becomes ductile and tenacious, and loses these properties by the action of fire, or by being burnt. According to Mr. Kirwan, it is of various colours, as white, grey, brownish red, brownish black, yellow, or bluish; it feels smooth, and somewhat unctuous; if moist, it adheres to the fingers, and if sufficiently so, it becomes tough and ductile. If dry, it adheres more or less to the tongue; if thrown into water, it gradually diffuses itself through it, and slowly separates from it. It does not usually effervesce with acids, unless a strong heat be applied, or that it contains a few calcareous particles, or magnesia. It consists of argill and fine sand usually of the siliceous kind, in various proportions, and more or less ferruginous matter. The argill, according to him, forms generally from 20 to 75 per cent. of the whole mass; the sand and calx of iron the remainder. These are perfectly separable by boiling in strong vitriolic acid.

It is remarked by Dr. Darwin, in his "Philosophy of Agriculture and Gardening," that the too great adhesion of the particles of argillaceous earth, or clay, renders it, in its pure state, unfit for vegetation; as the tender fibrils of roots can with difficulty penetrate it; whence it becomes much improved for the purposes of agriculture, when it is mixed with calcareous earth and with siliceous sand, as in marl. It is commonly believed, he also says, that lumps of clay become meliorated by being exposed to frost in its moist state, which, by expanding the water which it contains, by converting it into ice, is supposed to leave the particles of the clay further from each other. This, however, he says, seems in general to be a mistaken idea, since, if the act of freezing seems to occur, as noticed by Mr. Kirwan in his "Mineralogy," vol. i. p. 9, who observes, that clay, in its usual state of dryness, can absorb two and a half times its weight of water without suffering any to drop out, and retains it in the open air more pertinaciously than other earths, squeezing out its water, and thus parting with more of it than other earths. This curious circumstance, that water as it crystallizes detrudes the clay which is diffused in it, corresponds, he remarks, with other facts of congelation. Thus when wine, or vinegar, or common salt and water are thus exposed to frosty air, the alcohol, the acetous acid, the marine salt, and the calx of copper, are all of them detruded from the aqueous crystals, and retreat to the central part of the fluid, or to that last frozen, or into numerous cells surrounded with partitions of ice, as he has frequently observed; whence it appears, that wet clay is in general rendered more solid and tenacious by being frozen, as well as when it is dried, and its moisture exhaled by too warm a sun, and by both those circumstances becomes less adapted to the purposes of agriculture. In most clays a kind of effervescence occurs, after they are turned over and thrown on heaps, and thus acquire air into their interstices, which renders them much fitter for the purposes of vitrification, and thus forwards the processes of the brick-kiln and pottery. This greater facility to vitrify, is probably effected by the union of oxygen with the iron, which most clays contain; as oxydes of lead and manganese are used in the more perfect vitrifications. When the clay abounds with vitriolic acid, so as to be converted into alum, it becomes very unfriendly to vegetation.

It has been found in practice, that vast improvement in many of the lighter sorts of soil may be effected by the use or application of clay upon them. And Mr. Rodwell has experienced great improvement from it on the poorer sorts of sandy soils, which are very loose, and even on black sands. See Claying *of Land*.

It has also been remarked by Mr. Young, in speaking of marl, that when that substance "is not to be had, clay in many places is to be found at a moderate depth. This manure has," he says, "few of the properties by which marl is to be known, but yet it works wonderful improvements on many soils. In some light lands it has been preferred by many good farmers to indifferent sorts of marl; and this preference has been the result of attentive experience. But," continues he, "the great point concerning clay, is not so much the comparison with marl, as the use of it where no marl is to be had. On all light sandy soils it should be used with a confidence of success; for the precedents of its good effects are so numerous, that we cannot have a doubt of its excellence. About sixty or seventy loads an acre, at the same

expence

expence as of marl, will work an improvement great enough to shew how much mistaken those men are who think nothing but the finest marls worthy of attention; and upon heavier soils, as wet loams, brick earths, upon clay, and loose hollow soils, that want a firmer texture, clay is an excellent manure; but there are vast tracts of such land that cover very fine veins of clay, and yet farmers know nothing of the use of it. It is much to be regretted," he thinks, "that their landlords do not give them a juster idea, by being at the expence of claying some small fields until the benefit of the improvement becomes conspicuous."

Clay-*Balls*, in *Mineralogy*, are the name by which, in some places, the stony nodulous fossils called *Ludus Helmontii* are known. These are usually reckoned among the extraneous fossils, and are found of various sizes from four or five inches to almost as many feet in diameter; they are usually flattened irregularly, and appear externally, like masses of soft matter kneaded or moulded imperfectly together; their internal substance is cracked, apparently by the shrinking of their substance in drying or hardening, and the joints or septa are more or less coated or filled with spar, often of a waxen colour, whence this fossil is sometimes called *Septariæ*, or *Waxen-vein*. Clay-balls are found in many of the British clay strata, and are usually lodged therein with the utmost regularity, like pavement, often touching each other, as is the case with two remarkable layers of this fossil near the top of the clay on which London stands. In the cutting of the Grand-Junction canal from Paddington towards Uxbridge, and the Croydon canal from Deptford towards Croydon, these layers were cut through and exposed in a very complete manner for examination, for great distances together; they are sunk through in all the wells near London, where the clay stratum is complete, or where none of its upper part is abraded or washed away. Sometimes a small spring of water ouzes out of these layers of clay-balls, and the same is found to possess mineral qualities, and they are, we believe, the source of most or all of the mineral springs in the immediate vicinity of the metropolis. When exposed to the air, rain, &c. clay-balls soon split, and fall into an ochry powder, and at length mix with the soil; but the spar occupying the septa is sometimes very durable, and remains entire after the substance of the ball is mouldered away. An important use was a few years ago discovered for these curious nodules, in the manufacture of a cement for water-works and stuccoing of buildings, for which Messrs. Parker and Co. of Bankside, London, have a patent; they call it Roman cement, and the same is now largely used in the construction of the walls of docks, reservoirs, &c. and for imitating stone-work in buildings; the new door-cases to the Treasury-Chambers, in Whitehall, are a specimen of the valuable qualities of this cement, the same having been applied, in very thick layers at once, during an intense frost a few winters ago, and yet it set immediately, and stands the weather as perfectly as the best stone. The front of the House of Lords, and many other buildings in Westminster, are now covering with this cement, under the direction of Mr. James Wyatt, who has applied it with effect on the new palace at Kew, and in some additions and repairs at Windsor Castle. It is not certain that all the clay-balls, lodged in the different clay strata, are exactly similar in their composition, or adapted to the manufacture of cement; where, however, they can be had in plenty, it may be worth the while of the owners of the soil to procure their analysis and trial. See Ludus Helmontii.

Clay *Castle*, in *Geography*, is situate about a mile S.W. from Youghal, in the county of Cork, Ireland, where the pieces of the bank that break off and are washed down by the sea, are by degrees petrified into a hard firm grit. This is composed of a mixture of fine sand, and a yellow clay tempered by the sea water which beats against the hill. Wood and several other things daubed over with this clay are petrified on the spot. Smith says, there is a similar petrification at Harwich in England. Smith's Cork.

Clay-*Farms*, in *Agriculture*, such as have the lands either wholly or in a great part of a clayey quality. There are many extensive tracts in different parts of the kingdom where this sort of land prevails, and which have been often cultivated to much disadvantage from the want of a due mode of cropping, and their not having of course a sufficient proportion of green winter food for the support of the requisite number of live stock, and the raising of the necessary quantity of manure. It has been suggested that these inconveniences may be fully obviated by having recourse to the cabbage husbandry. See Cabbage and Farm.

Clay *Hill*, or Copt-Heap, in *Geography*, a remarkable eminence on the south west branch of the grand ridge of England, about two miles W. of Warminster, and near the edge of the Chalk strata. The situation of the barrow or tumulus on the top of this hill was determined in the government trigonometrical survey in 1794, by an observation from Beacon-Hill station, distant 117,216 feet, and bearing 85° 54″ 8″ S.E. from the parallel to the meridian of Dunnose; and another from Wingreen station distant 84,554 feet; whence is deduced its latitude 51° 12′ 13″, and its longitude from Greenwich 2° 13′ 25″.8 W. or 8ᵐ 53ˢ.7 in time.

Clay-*Mill*, a machine used by the brick-makers near London for tempering their clay. In *Plate* XII. *Mechanics*, are represented two of these machines. In *fig.* 10, which is the most common, A B is an upright shaft turning on a pivot at the lower end, which works in a brass socket let into a piece of wood lying on the ground; the upper end has a similar pivot, the brass is fixed in the intersection of two beams, C D, of the frame; these beams are supported by four uprights at their ends, which are firmly fixed in the ground; the whole is braced together so as to form a very steady frame for the shaft A B to turn round in. E, F, G, H, are four arms mortised in the shaft somewhat below the middle, supported by braces from the upper part of the shaft, and connected together by four braces in the form of a square; the two arms, E, F, are longer than the other two, and have hooks, by which the horses draw, fastened to them. They have also each two irons, *ab*, *ab*, attached to them, whose lower ends work at the sides of a circular trough or ditch, KK, which is concentric with the shaft A B, and walled with bricks. The ends of the levers, G, H, carry harrows, L, M, (*fig.* 11.) working in the same trough; these harrows are sometimes fixed to the arms, as at G, by three struts, and sometimes they are connected with the levers by four chains, and loaded with heavy weights, as at H, and better explained in the following figure.

When the machine is in use, a quantity of clay is thrown into the circular trough, K K, which is about one-fourth filled with water by a pump, the trough from which is laid under the horse-walk. The horses are then put to the ends of the levers, E, F, and set in motion; as they turn the machine round, the harrows, L, M, drag the clay round, in the trough, and by agitating it in the water, soon dissolve part of the clay, forming it into the consistence of thick mud; as the horses continue to work and more water is added, the whole mass is thoroughly incorporated; a sluice, N, is then opened which allows the clay to run out into shallow pits, which are dug in the ground at some distance round the mill, and a little below its level; in these pits the clay is suffered to remain until the greater part of the water is evaporated; it is then dug out and carried to the brick-maker. The pump for

for supplying the mill, is in general worked by a man, but in the machine before us, it is worked by the mill; at the upper end of the shaft, AB, *fig.* 10. a wheel, P, is fixed, which has wooden projections nailed to it; these take the end of a lever, Q, moving on an iron bar, *d*, as a center; the weight of the lever is supported by a friction-wheel running on an horizontal bar R, fixed to the frame-work above; the lever, Q, has a rod, S, jointed to it near its end, which is supported by a frame, T, fastened to one of the upright posts, the end of this rod is jointed to one arm of a bent lever, the other arm of which has the pump-rod of the pump, O, hooked to it. As the horses turn the wheel its teeth move the end of the lever Q with it and raise the pump-rod; when the tooth quits the end of the lever the weight of the pump-rod pulls back the lever to its original position, ready for the next stroke; by this contrivance a constant supply of water is easily procured, and, by preventing the descent of the pump-rod, the pump-work is stopped when there is water enough. The iron bars, *a b*, *a b*, are intended to remove the clay which may get to the sides of the trough KK, and by that means escape the harrows.

The machine represented by *fig.* 11, though not so common, is much more simple in its construction. A is a stout post firmly fixed in the ground; it is hooped at top, and has a brass socket in the centre to receive the point of an iron pin, *a*, which goes through the intersection of two levers, EF, GH; this pin has a cast-iron plate, *b*, fastened to it, that is bolted to the lever, so as to connect them together. I, I, I, I, are four braces to strengthen the cross. O, O, O, O, are four other braces which carry a circular ring, R, and the whole is strengthened by four long screw bolts *d, d, d, d*; this ring fits the post loosely, and when the horse turns the machine it moves as steadily as the former machine; the harrows and the circular trough are the same. The two preceding machines are used, in those places where the clay used by the brick-makers is not very clean, but has many stones and other extraneous matter among it, as they sink to the bottom of the circular trough, and remain there when the clay is drawn off. Where the clay is naturally sufficiently pure, and requires only to be tempered, a different machine is used; it consists of a cylindric tub about three feet diameter and four feet high, in the centre of which is a vertical spindle, the lower end working in a brass socket at the bottom of the tub, the upper end turns in a collar supported by two iron bars nailed to the sides of the tub; at the top of the spindle, above this collar, a long lever is fixed for the horse to turn the spindle by; the upright spindle has six or eight arms fixed perpendicularly to it in different planes, working within the tub; these arms have spikes projecting from their upper and under sides, the tub has a small trap door in the side, near the bottom, which can be kept closed by a hasp; the clay is thrown in at the top of the tub, and the horse made to turn the spindle, the arms and the spikes fixed to it, cut the clay in every direction and mix it thoroughly, water being added in the proper quantity. When it is sufficiently ground the door at the bottom of the tub is opened, and, as the horse turns, the clay is thrown out, and carried to the brick-maker.

Clay-*Stone*. See Clay *indurated*.

Clay *Strata*, in *Mineralogy*. The recurrence of clayey strata, in the sinking of deep wells, and shafts for mines, in England, is more common than those of any other matter; and since the discoveries, and meritorious labour of Mr. William Smith, on the stratification of these islands, have been known among the circle of his friends, opportunities have offered, of ascertaining the peculiarities of the organic remains most commonly lodged in these strata. In the south-eastern part of England, or uppermost parts of the series of British strata, these are, cornua ammonii, belemnites, corallines, or coralloids, entrochi, gryphites, bituminous wood, &c.; at the same time that ludus helmontii, iron-ore, or ochre, pyrites, selenite, or gypsum, mica, &c. are not unfrequently found lodged in these clay strata.

The uppermost, or first clay stratum (or rather assemblage of clay strata) in the British series, is that on which the metropolis of the British empire and its environs stand; its upper part is red, and very tenacious when wet, forming perhaps one of the worst strata for cultivation, in England; which, but for the great population thereon, and consequent opportunities of obtaining manure, for a series of ages back, would probably, to the present day, have been in a similar state to the wastes or commons, with which the vicinity of London has been so often reproached. Near the top of this stratum, there are two remarkable layers of clay-balls, or ludus helmontii, as observed under the article Clay-*Ball*, and lower down, pyrites, and other fossils; a layer or stratum of sand, containing black particles, occurs near the bottom of the London clay strata, which, in the sinking of wells, is sometimes found nearly dry, and at others produces a spring of unpalatable water. Beneath the London clay strata, a thick sand stratum is found, resting upon the chalk strata, and, by means of the numerous and large cracks and fissures in the *chalk*, the sand is supplied with a most powerfully pent or confined spring, which often rises near 250 feet, on the sinking of a well, through the clay strata above mentioned, and runs over the surface, as in Mr. Vulliaumy's well, near Kensington Gravel-pits, described in the "Philosophical Transactions" for 1797, and many others in and near London, which have been sunk within a few years past. Near the bottom of the London clay strata, there are layers, or strata, of smooth, flat, and round chert pebbles, of uniform sizes, which do not appear to be worn or rounded fragments of a chert rock, but nodules, many of them consisting of concentric layers, originally formed, of the particular sizes in which we now find them.

The next clayey stratum in the British series, is found beneath the chalk strata; from its white colour, it is denominated chalk-marl in many places; when overflowed, and kept wet, by springs from the edge of the chalk strata, as at the foot of the chalk hills N. of Dunstable, this chalk-marl is very tenacious and barren; but where its out-crop is dry, as on the south side of the North Downs, near Ryegate, Godstone, &c. or the north side of the South Downs, as at Clayton, Plumpton, &c. its surface forms very good land, particularly for wheat; while the inner parts of it are, in such situations, disposed to harden into a substance almost like stone, in thin laminæ. Cornua-ammonii, shark's teeth, and a curious variety of extraneous fossils, are found in this chalk marl, of which we hope that the publication of Mr. Smith's intended work, will enable us to give a more detailed account, under the head of each fossil, as we arrive at the same in the progress of our work.

The next considerable assemblage of clay strata which we meet with in the British series, has a remarkable stratum of red potter's-clay on its surface, on which there is a variety of tile and pottery kilns in Sussex, beneath which a whitish tenacious clay is found, and therein a thin stratum of lime-stone, called Sussex marble, in many places where it is used, particularly in the slender grouped pillars of Gothic buildings, like Westminster Abbey; this thin and curious stratum of lime-stone, consists almost entirely of a congeries of turbinated, or perriwinkle-like shells, of very uniform sizes; in some specimens these are all smaller than pease, and in others they are of the ordinary size of perriwinkles; whether these are the produce of different beds in the same stratum, or whether a thickness of clay separates them, we have not yet been able to to ascertain. This subject we must, for the reason above stated, resume on future occasions.

The most usual vegetable productions found upon clay strata, are of the following genera; *viz.* in wet situations, carex, juncus, schœnus, aira, orchis, carduus, poterium, salix, &c. while, in dry situations, the following prevail, *viz.* primula, arum, rhinanthus, orchis, poa, rosa, rubus, prunus, acer, quercus, &c.

CLAYE, in *Geography*, a town of France, in the department of the Seine and Marne, and chief place of a canton in the district of Meaux, 2½ leagues W. of it. The place contains 1007, and the canton 10,725 inhabitants; the territory includes 195 kiliometres, and 25 communes

CLAYES, in *Fortification*, are wattles made with stakes, interwoven with oziers, &c. to cover lodgments.

CLAYETTE, La, in *Geography*, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Charolles, 3½ leagues E.N.E. of Marcigny. The place contains 1089, and the canton 10,887 inhabitants; the territory comprehends 202½ kiliometres and 17 communes.

CLAYEY Land, in *Agriculture*, that sort of lands in which the clayey ingredient is more or less abundant, and which differs very materially in proportion to the nature and qualities of the clay, as well as the quantity in which it enters into their composition; some being extremely sterile and unproductive, while others are capable of affording an abundant produce of different kinds of vegetable crops.

According to the observations of the very intelligent and able author of the "Treatise on the Connection of Agriculture with Chemistry," there is no clayey land or soil that is pure and free from sand; and there are but few clays that are free from a mixture of calcareous matter, magnesia, vegetable and animal matters, mineral oil, and other mineral or metallic substances; some clays are of a much more unctuous, and, as it were, greasy nature than others. They do not differ more in this respect, than they do in the appearance they assume, when submitted to a moderate degree of heat. Those clays which are the most unctuous and greasy to the touch, are, by calcination, changed to a black colour. This must be owing, either to their containing animal or vegetable matter, although, previous to calcination, it escapes observation; or, the inflammable matter in the clay may exist in the state of a colourless mineral oil, adhering obstinately to the clay, and not capable of being separated from it by water, with which oil can hold no union; yet capable of being changed into a black carbonaceous matter by the action of fire. A due mixture of clay, serves the important purposes of retaining in the soil the attenuated vegetable and animal substances, as also the mineral oil. Of this description are those clays, or clayey loams, which have been deposited by the sea, or muddy streams, containing a considerable proportion of the exuviæ, or remains of animal and vegetable bodies, in an extreme degree of attenuation. Such lands as these are the most permanently fertile, and, where the climate is favourable, produce the heaviest and best filled grain. He further states, that soils, formed by depositure, for the most part contain a sufficient quantity of calcareous matter. Adding lime to such lands may prove injurious, by its expending, taking up, or otherwise altering the arrangement and combination of the animal and vegetable matters, which should carefully be preserved for succeeding crops. Under any circumstances, lime should, he thinks, be given to such soils but sparingly. But there are clayey soils containing little or no animal, vegetable, or bituminous matter, and which are equally deficient of calcareous matter, consisting only of clay, sand, and the earth of iron. To improve and render fertile a soil of this description, is truly an Herculean task, and will seldom repay the industry of the cultivator, unless situated in the neighbourhood of a town, where more dung may be procured than can be spared from the farm in its contiguity. A soil of this nature can receive little or no benefit by the application of lime, as it contains nothing for the lime to act upon or combine with. When under such circumstances, that dung, or such like manure, cannot be procured, a preparation of peat, with a very moderate proportion of lime, seems to be the next best application. A soil of poor lean clay, such as above described, will, he says, require 8 tons of lime, and 48 tons of peat, for one dressing. Doing things partially can never answer; this quantity is the least that ought to be applied; a much greater may be given, if the articles can be cheaply and easily procured. In this the farmer must be regulated, in a great measure, by his ability in doing, or extent of his capital. His primary object, in this case, should be to promote the growth of pasture grasses, because the land or soil at first will be in no heart to produce crops of grain; and, secondly, because the promoting of the growth of such grasses, and judiciously depasturing and folding, is the surest way of improving such lands. After the grass has taken hold of the ground, and is beginning to carry a tolerably thick sward, its thickness and quality may be greatly improved, by some one or more of the top-dressings, or preparations, recommended under that head. See Top-Dressings.

It is evident that clayey lands are therefore as different in their natures as in their colours. Some of them are so obstinate that it is scarcely possible to subdue them. Others are so soft and unctuous, as to be easily reduced to a proper state for nourishing plants; while others, again, are so hungry, as to absorb in a short time whatever kind of manure is applied, without either materially altering the nature of the land or soil, or improving the crops. Clay being, as has been seen, a solid compact body, and its particles adhering firmly together, it does not easily admit water, although capable of receiving a large quantity, nor does it part with it but by slow degrees. When dry it is hard and dense; and the more rapidly water is drained off or exhaled, the harder it becomes, frequently opening into small chasms or rents, when suddenly dried. As clay, from its tenacious quality, retains water longer than any other soil, the roots of the plants, in a rainy season, are frequently soaked in water for a considerable time, and the plants themselves, if not entirely destroyed, are so chilled and weakened as to produce very indifferent crops. On the other hand, from the natural closeness of its texture, added to the circumstance of its hardening very quickly and to a great degree when the moisture is suddenly extracted, the plants in a dry season are prevented from extending their roots in search of nutriment; while the dews and light summer showers, so essential to the growth of all vegetables, and which easily penetrate the more friable soils, are repelled by the clay, and again exhaled by the influence of the sun. From this account of the nature and properties of all clayey lands or soils, it is scarcely necessary to mention the great importance of keeping them as dry as possible at all seasons, especially during winter. When that is properly attended to, the farmer has it in his power to plough and sow on the first return of favourable weather in the spring, as thereby, in a great measure, he avoids the risk of his crops suffering either from heavy falls of rain, or a long continued season of dry weather, particularly the latter, for when a clayey soil is reduced to a proper state by the harrows and rollers, after the seed is sown, it very seldom happens that the crop sustains any material injury from the want of rain during the remainder of the season. But although the nature and properties of clayey lands be such as above described, yet, by industry,

industry, and the application of such manures as are best calculated for correcting their bad qualities, and for bringing those most favourable to vegetation into action, this sort of land is often made to produce abundant crops, of many different kinds.

But clayey lands, of whatever kind they may be, the author of the "Synopsis of Husbandry" thinks "require a more laborious exertion to reduce them to a fineness necessary for the purpose of husbandry than any other soils, and are distinguished under various names, arising from the colour; but the intrinsic good or ill quality of this soil depends not on these vague distinctions, but on the proportion of sand intermixed with it; and where this ingredient is happily blended with the clay, and where the soil is of a reasonable depth, and the springs do not rise too near the surface; when these several good qualities are united, there are few soils more kindly for the several purposes of husbandry; and though in their cultivation the clays may require a greater strength both of horses and tackle than any other, yet, on many accounts, they deservedly claim the preference either to a chalk, gravel, or sand." Of this kind, he observes, are the lands in the wealds of Kent and Sussex; and he knows of no part of the kingdom where the several purposes of husbandry are more effectually answered than in these counties: the size and fatness of the beasts evince the fertility of their pasture, whilst the luxuriancy of its several growths of hops and corn proclaim the superior goodness of the arable land; and the large spreading oaks are a demonstrable proof that it is kindly to the growth of timber. But there are other kinds of clayey soils which, being by nature so stiff and tenacious as not to be meliorated either by tillage or manure, bid defiance to the most skilful plan of husbandry, and can never be brought to yield a sufficient quantity of earth to heat the seed, unless in a season the most propitious; and even with every advantage that can attend it, this ground will fail to produce a crop by any means adequate to the pains and expence required in working it; so that it demands some judgment to discriminate the various kinds of clays, which, though they all rank under the same general denomination, do yet differ most essentially in their properties. Those of the more sterile kind are rarely of any considerable depth, having a bed of gravel for the under stratum, and are generally within a near proximity to the springs; for this kind of land being always overcharged with wet, or parched with drought, and therefore subject to accidents which it is seldom in the power of the husbandman to foresee or prevent, is, on these accounts, inferior to most others: whilst clays of the first denomination are deservedly ranked, as has been observed, among the most fertile soils. To determine the goodness of a clayey soil, one should have recourse, he says, to the appearance of the trees, corn, and other vegetables: the prosperous growth of the trees and hedges, the flourishing state of the corn, and the verdure of the meadow-land, are favourable omens; whilst the stunted appearance of the trees, thin crops of corn, and short grass, are plain indications of the poverty of the soil.

"In the business of tilling this kind of land, the renter will act wisely," he says, "in providing himself with stout and able horses, strong ploughs, and other instruments of husbandry; and his hinds, likewise, ought to be those of the most hardy breeds. Of the many different kinds of ploughs now in use, there are none better adapted for working these stubborn grounds than those commonly distinguished by the name of swing-ploughs: these are constructed without wheels, and the horses draw singly, following each other in the furrow, in both which respects this plough claims the preference to wheel-ploughs, where the horses, by going a-breast, tread the ground much more than in the former instance; though in Kent the farmers usually work their stiff land with the common turn-rest, or, as it is vulgarly called, turn-rise plough, which is made far more weighty than the Hertfordshire or any other wheel-plough; and, from the circumstance of turning the rest at the end of every furrow, is not chargeable with the defect before mentioned, of subjecting the fresh ploughed ground to be trodden by the horses. In some counties they till their stiff lands with a foot-plough, which, by means of the iron that is let into the beam, and rests in the furrow, works with more steadiness than the swing-plough, but in the other parts of its construction nearly resembles the last-mentioned instrument. As most of the ill qualities attending the soil originate in its adhesive nature, every art should be made use of to meliorate and pulverise the stubborn clods, so as to reduce them to that degree of fineness necessary for the purpose of vegetation."

"And in the practice of winter-fallowing a clayey soil, let," says he, "the ground that is proposed to be sown with oats or beans in the spring, be fallowed up as soon as possible after the wheat season is finished, and be careful that the lands may not be made over-large; perhaps five bouts or wents may be a proper size, so that each land may measure about half a rod over; but this is to be determined by the nature of the soil and the locality of the situation. It has been shewn already, that clays differ essentially from each other, and hence it seems of consequence, at the fallowing of those which are of the wet, spewy kind, to lay the ridges in such manner that they may be least incommoded by the winter rains; whereas, in those of a moderate texture, and which are less inclined to moisture, this caution is not necessary, but to guard against the contingency of moisture during the winter, by laying the land as dry as possible, is a point to be attempted by all possible means on every different description of this soil. The ground having been thus fallowed at an early season, and having partaken of the benefit of the winter frosts, will generally work kindly towards the middle of February, which is the proper time for planting beans on clays. For oats, perhaps, three ploughings may be required, provided the season be favourable for performing them; for, in a very wet spring, it may be more prudent to dispense with one ploughing, and to sow after the first stirring in April; but if the weather be kindly, it will be advisable, when the bean season is finished, to stir such ground as is intended for oats; and this fallow, having enjoyed the benefit of the March winds, will work well at the second stirring in April, the proper time for sowing oats on stiff lands. The ground having been thus managed, will come in for beans the next year, or be in a state of tillage proper to sow with clover, which generally suceeds well when cultivated on these soils; and fields which were put in with beans, if the ground be in good heart, will come in for a wheat season at the following autumn. And this shews how necessary it is for a farmer to look forward, in order that his land may not only be well prepared for the growth of the present crop, but be in readiness for the reception of a different grain in the following years."

In fallowing for wheat in clayey lands, it has been already observed, he adds, that "wheat might very properly succeed a crop of beans on these soils, a method which is generally pursued in Kent and Sussex; but where the land is of a very stiff nature, it is absolutely necessary to give it a summer fallow once in four or five years or oftner, according to its goodness, by which method its adhesion is destroyed and the pores are opened for the admission of the sun, air, rains and dew, all of which abound with such principles as may

may contribute, in a high degree, towards the melioration and fertility of the soil. The proper time to fallow for wheat, on a clay, is in the month of April, as soon as the lent season is finished; and if the weather will permit, the stirring should be effected in May, and this is sometimes all that can be done to the field till after the rains in August; for, should a dry time happen in June, it will be impracticable to work the land, it having been rendered so hard as to preclude the entrance of the plough, or if this can be effected, the surface will, in this case, break up in such large clods, and withal so shallow, as to render the tillage of little worth; but should the weather permit, it will be proper to give the ground a second stirring in June, and to lay the fields in ridges; for in such form the soil will more conveniently imbibe the various influences of the atmosphere, than in broader lands. The number of ploughings throughout the summer depends so much upon contingencies, that no stated rule can be laid down upon that head; for if the weather be either too wet, or tending to the contrary extreme, this work of the more obstinate kind of clays will be wholly impracticable, and on this account, the farmer is frequently disappointed of a wheat season; but on clays which are less adhesive, and where the land has been conducted in a husbandlike manner for a series of years, there is not so much hazard of being thrown out at the wheat season; and a time generally offers for sowing the corn between the latter end of August and the beginning of October, which is the latest term to which the sowing of this grain ought to be protracted on these heavy lands. If the weather shall have been kindly throughout the summer, the land will have been stirred at least twice during that period: and thus with the fallowing, and the last ploughing at seed time, the ground will have been four times ploughed, which will most probably have reduced it to a degree of fineness proper for the reception of the wheat, after which the field should be sufficiently harrowed, so as to cover the corn to a proper depth."

And it is observed, by the practical author of the "Present State of Husbandry," that "the manures most proper to be applied to these lands, are lime, chalk, sea-sand, and ashes. It appears, he says, from the accounts given by those chemists who have analized these substances, that they are admirably calculated to correct the stubborn density of clay, so as to render it more easily reducible by the plough; to open its pores, so that it may more readily imbibe and transmit water; and that they operate as a powerful stimulus, and some way or other dispose whatever principles in clayey soils are friendly to vegetation, to exert themselves. Long and established practice confirms this observation: lime, for instance, has been applied to these soils for many years in the counties of Durham, Gloucester, Hereford, Montgomery, Berwick, Stirling, Perth, and many other districts where such soils prevail. Chalk is used both in its natural and calcined states, in Hertford, Middlesex, Essex, Kent, Wilts, and other southern counties. Sea-sand is employed as a manure in Cornwall, Devon, Pembroke, Anglesey, Caernarvon, and also in several districts in Scotland. Coal-ashes, in the neighbourhood of London, are laid with astonishing success on clayey-soils, whence brick earth has been taken. Peat ashes have produced wonderful effects in Berkshire; and ashes of both kinds are used to great advantage, as a top-dressing on the strong soils, in all those counties where that practice is established. Besides these manures, composts, especially when formed chiefly of light sandy, or gravelly earths, with lime and chalk, are also applied to clay soils with success in many parts o fEngland. Few composts being made on the better cultivated clayey soils in Scotland, the common method is to lay on farm yard dung, the same season in which a field is limed; by adopting this practice the lime is found to operate more rapidly, and at the same time more powerfully."

It has been remarked by lord Dundonald, that "there is a great extent of poor clayey land or soil, similar to that which has been mentioned, in many parts of the north of England and in Scotland for the most part lying at a considerable height above the level of the sea; and frequently in the vicinity of peat mosses in the county of Lanark, or Clydesdale, he says, there are computed to be 40,000 acres of peat-moss totally unimproved, producing nothing itself nor contributing in any way to the fertility of the adjacent poor lands, which are as destitute of vegetable matter, as the moss contains a superabundance. It requires a much longer time, and a much greater application of dung and vegetable matters, than would be generally believed, before poor lands of this description can be rendered highly fertile, and made in all respects, similar to land that has been long, or for ages under cultivation. Ten times the quantity of peat, or vegetable matter, recommended to be given at once, or 480 tons would scarcely bring poor barren land to the colour of rich black mould, known in Scotland by the name of infield-land, and to which, for ages, the dung of the farm has been exclusively applied. Experiments made with an intimate mixture of poor lean clay and peat warrant this assertion; here purposely stated, he says, that the over sanguine cultivator or improver of ground may not imagine, that with a summer fallow, and a dunging or dressing or two, he may be enabled to complete so arduous a task. Land is always requiring a supply of manure, and repays, in general, more abundantly for the last expence when brought to an advanced state of cultivation, than for that which at first is incurred. Both seed and labour are thereby saved, and good crops, with much more certainty, are to be depended upon."

"Paring and burning the sward of some clayey soils, he thinks, may be practised with advantage, as the burnt clay will diminish the stiffness of the soil, and render it more pervious to water. This may be still more economically effected, and in other respects, with less injury to the soil, by half burning the clay, in clamps or in kilns: a preference which can however only be given in situations where fuel can at a cheap rate be procured for this purpose." See Burnt *Clay*.

Mr. Donaldson says, that, "while it may be admitted, that, by the application of such manures and proper cultivation, clayey lands are made to produce, occasionally, luxuriant crops; to every person acquainted with these soils, it must be obvious, that the crops are, upon the whole, more precarious and uncertain than those on deep fertile loams, and other similar soils or sorts of land. And the natural produce of clay-lands, with regard to weeds, is rushes, goose-grass, or wild tansey, large daisies, thistles, docks, May-weed, poppies, and other coarse herbage of a similar kind."

The following is the method of improvement that was employed in the bringing of a tract of ninety-three acres of clayey-land which had remained long in an uncultivated state into a proper condition, in order to lay it to grass, as practised by Mr. Best, and stated in the fourth volume of "Communications to the Board of Agriculture." "These lands," says he, "since the memory of man, were let at 18 *l.* per annum: from this sum they increased, owing to the advance of the times, to 22 *l.* 5 *s.* which is the most they were ever let for." In the year 1788, he began on a field of eight acres, by employing some men to take up brambles, furze, and other natural incumbrances, with which

which two parts in three of that field were covered; in the winter he had it under-ground drained. This, he thinks, is the first step which a farmer ought to take, before he converts his land to tillage. He laid the top turf on two shoulders, about sixteen inches deep, leaving a channel open under, which got the land very dry, and so it continues. The expence of draining, when he first began, was about 30 *s.* an acre, but now it is near 40 *s.* In December, 1790, he ploughed the whole of this field, and in the February following, spread about ten tons of well-mixed dung and earth over every acre. In April he sowed it with flax; this is a crop that requires, (particularly in strong land, which this is, being on a strong clay, with some spots of flinty gravel), in its early part, at least twelve hours rain in every week. Unfortunately for him, he had not half rain enough; consequently, that crop failed. He then made as good a fallow, as the nature of the land and the season would permit. At Michaelmas, 1791, he sowed it with wheat, which produced about eighteen bushels (single Winchester) per acre. As soon as the ground was cleared of the wheat, it was ploughed and sown to vetches, of which he had a great crop; he fed these off with sheep in the spring, 1793, and the ground which they cleared by day they lay on at night. After the vetches were all eaten, he made a very good fallow, and, in September, dressed it over with ten hogsheads of lime (which cost 1 *s.* 6 *d.* per hogshead), per acre, which he had, in the month of May, mixed with the head-lands well together. About Michaelmas, he sowed it with wheat again, and had too great a burden; for, in the month of May, 1794, he was obliged to have a man with a keen reap-hook, to cut off all the luxuriant blades, the ear not having made its appearance. This precaution, however, did not fully answer his purpose, for a great part of the crop was thrown; notwithstanding, he had full twenty-five bushels per acre. He then made a fallow, and, in the spring 1795, sowed the field with white oats and grass-seeds of different sorts, *viz.* rye-grass, cow-grass, Dutch clover and hop. The oats were very thick and long; in consequence of which, the grass-plants in some places did not thrive; for, in spots of five or six feet square, there was no appearance of any. He had eight quarters of oats per acre. He fed the grass with sheep the years 1796, 1797, and till August, 1798, when he again ploughed it, and dragged in some vetches. He had a great crop, and, in the spring 1799, fed it off with sheep, folding them on the ground as they eat the vetches. When this was done, he made a fallow, as good as a wet summer would admit of, and sowed it to wheat again, at the usual season, without any additional manure, and had about twelve bushels per acre, a good crop for this year, some lands in the neighbourhood not producing more than six or seven. The acre in this county is customary measure, not statute.

It is added, that, from finding this land drained so well, he has, every winter, drained a little, as fast as he could get the land cleansed; and last winter he completed the whole ninety-three acres. He has drained a great many acres of land besides these, and has had it done in the same manner, which answers extremely well. Twenty acres of the above, ninety-three he has kept in pasture, having, in the space of five or six years, dressed it over twice with about fifteen tons per acre each time. His manure consists of dung, earth, soap-ashes, and the scrapings of turnpike roads: this latter article answers remarkably well on a strong clay soil. The whole of these ninety-three acres are on such a soil, with some gravel. During the summer, it is necessary to turn it twice, in order that it may be well mixed; and, by doing this, it is brought to a fine mould; when spread on the lands, once brushing over with some thorns makes it soon disappear. The above twenty acres are at this time worth 25 *s.* per acre. In November, 1795, he began ploughing another piece of ground of fourteen acres. From the manner in which this piece of ground lay, his servant could not throw it plain, (it being left, the last time it was ploughed, in six-furrowed ridges), so as to bring it with any advantage to a crop in the spring. In April, 1796, he ploughed it across; after this, worked it well with drags and barrows. Finding this would not do (owing to the turf not being sufficiently rotten, which he accounts for, by lying in a rough open state all the winter), he set some men to hack it over: and, harrowing it well with four horses abreast, it became tolerably fine, with the exception only of the rush and sedge, of which there was a great abundance. The weather being dry, he employed twelve or fifteen women and boys beating over these rush and sedge roots, in order to get them out of the earth, some men going after them with three-pronged forks, throwing them in heaps and burning them. By doing this, he raised a great quantity of ashes, which he spread over the land, and, as soon as sufficiently cold, he harrowed in some turnip seed, which came up very well: but the land being of a close stiff nature, they did not get larger than about the size of a cricket-ball; he had them hoed, otherwise they would not, in his opinion, have grown to that size. He kept 450 sheep upon them, with a little hay, a month and a few days. In the month of May, previous to this, he put on the head-lands 140 hogsheads of lime, which he caused to be well-turned and mixed, and, as the sheep ate the turnips, this was carried and spread on the land. The latter end of October it was sown with wheat, and produced a good crop, averaging better than twenty bushels per acre. As soon as the wheat was carried off, it was ploughed and sown to vetches (a greater burden than lands of the value of 40 *s.* an acre could produce;) and in the spring 1798, he fed them off with sheep, folding them by night, where they fed by day. He always makes it a point, as soon as the sheep have cleared a day's work for the plough, to plough the land; by doing this, he preserves the manure of the sheep from the sun, and turns in what vetches were left, which, in his opinion, are equal, if not superior, to the droppings of the sheep. He has observed, that where the greatest quantity has been left and ploughed in, that part of the ground generally works much lighter at seed-time; and that, at harvest, the wheat is superior. This may not do so well on a light sandy loam. He finished sowing this field to wheat (the second time) by Michaelmas, 1798. He was obliged in May to cut off all the tops of it (as he did in the other field), in order to keep it standing. When harvest came, he had sixty tithing per acre, which produced no more than 300 bushels, and about two pecks in the whole field. If the kern had been such as it was the year before, he should, he believes, have had thirty bushels per acre. Last year it was sown to barley and grass-seeds. As the barley is not threshed, he cannot exactly state the quantity grown, but, from appearance, it was judged to be about twenty bushels per acre: a good crop for this country last season; the grass plants look remarkably well, and consist of the following sorts:—rye-grass one peck, cow-grass 6 lbs., Dutch clover 2 lbs.; this he allowed for every acre. It is customary, he says, for the tenant to be at the expence of the grass-seeds. The hop-grass did not answer in the other field; it is his opinion that the soil is too heavy and close for it. He very much disapproves of mowing the first year after laying down, particularly on strong lands.

 He

He further states, that, in November, 1795, he ploughed another field, of eleven acres, and threw it very plain. As soon as it was finished ploughing, he had it rolled with a heavy roller, that it might be as close as possible all the winter, in order to rot the spine or turf the better. In the early part of April he dragged in some black oats; shortly after they were up, an easterly wind (to which the field lay quite exposed) struck them very yellow, exactly like straw, and the ground being so very poor, they never recovered it. The ground lay in this state till September, when it was ploughed across, and so it remained till the March following. The frost having opened it, and by dragging and harrowing it well, he brought it to be tolerably fine. In May he dressed it over with 20 hogsheads of lime per acre, (which was well mixed with the head-lands in April), then ploughed it as thin as possible, and sowed some turnip-seed, which came up very well, but did not flourish, owing, in his opinion, as he has before observed, to the soil being too stiff and heavy for turnips. At Michaelmas, 1798, it was sown to wheat without any other manure. The crop produced him nineteen bushels per acre. As soon as the wheat was carried off the land, he sowed it to vetches (which he is convinced is the best artificial sowing on strong lands), and he had a very good crop, which he fed off with sheep in the same manner as before described; and last Michaelmas it was sown the second time to wheat without any additional manure; at present it is impossible for plants to look better. He intends taking three crops from this field, as he did from the last, and then to lay it down for three years. He thinks no land should have more than three crops of corn without rest; at the same time sowing between those crops, some sorts of artificials, for sheep-feed, which will keep the land clean and in good condition. The soil will dictate to the farmer what sort of artificials to sow for his advantage. He has, at this time, another field of ten acres in fallow, which has been ploughed these twelve months. He intends pursuing exactly the same method with this and the remaining thirty acres, as he has done with the former, and when finished, he has no donbt but that the ninety-three acres will be worth one hundred pounds per annum.

The great advantage of adopting proper modes, in bringing lands of this nature into the state of good grass, or *sward*, is here shown in a very striking manner; and it is rendered still more evident in the practice detailed below.

In respect to the breaking up and re-laying clayey land to the state of sward, Mr. Amos has observed in the same volume of "Communications," that it is the most obdurate and unmanageable soil which the farmer has to encounter, the too great adhesion of its particles rendering it unfit for vegetation, but which may be in some degree corrected by lime, sand, ashes, long dung, marle; by frequently exposing fresh surfaces of it to the influence of the sun and atmosphere; by planting on it succulent plants, as beans, red clover, &c.; which having top roots not only render the mass less cohesive thereby, but also add to it much carbon. And that as the lower leaves of the dense foliage of these vigorous vegetables also give out much carbonic acid by their respiration in the shade: which, perpetually sinking down upon the surface of the soil, supplies it with carbon, which renders it more nutritive to other vegetables, which may afterwards grow upon it. The mode displayed at fig. 1. in Plate X. on *Agriculture*, answers the purpose in the most effectual manner, as shown by the section of a 12 feet ridge.

But in breaking up grass land of this kind of soil, great attention should be paid to ploughing the furrows, so as to expose the greatest surface possible to the influence of the sun and atmosphere, and to furnish the greatest quantity of mould for covering the seed.

It is supposed that furrows nine inches broad and three inches and a half thick are the best proportioned size. He is however truly sensible that no certain standard can be fixed for the breadth and width of the furrows; that must entirely depend upon the depth of the soil. By limiting the breadth and thickness of the furrow as above, he only means that those proportions should neither be much exceeded nor abated where the staple of the soil will permit.

"In regard to the first crop, as the size of the ridges is already formed upon all grass lands, nothing can be done, but to plough the ridges in the manner described, early in February. As soon as the weather permits, in the last week of February, or on the first or second week in March, to sow five bushels of good oats upon every acre; then to harrow the land only just enough to cover the seed; afterwards to let the whole be water furrowed, and the drains opened, so that no water may stand upon the land. Nothing more is wanted to be done till the latter end of May or beginning of June, when the crop should be well weeded.

And for the second crop, the land should be gone over "early in November to see that no water stands upon it, and that the water furrows and cross grips or drains are kept clear and open. And as soon in February, as the weather and condition of the soil will permit, to drill ten pecks of beans upon every acre, twenty-seven inches between each row and three inches deep; then to harrow the ridges twice or thrice with *swinging trees* as long as the ridges are broad, to which as many harrows should be tied as will cover them, and the horses walk in the open furrows. But as soon as the beans are fairly above ground, they should be rolled and harrowed; some time in May be horse-hoed, by ploughing a furrow off from the beans on each side, making a ridge in the intervals between the rows. The beans will then stand upon a ridge of about six or eight inches wide, which must be well hand-hoed. In about a week after, the earth must be returned again to the beans in the rows. In about two weeks more the double mould-board plough should be used to scour up the middle of the intervals, and to lay the earth closer to the beans. If any more weeds appear they must be pulled up by the hand. And as soon as the ground is cleared of the beans, the land should be scuffled the cross way of the ridges, then harrowed once or twice, and the weeds collected in heaps and burnt.

"And early sowing should be practised, as the mildew is more injurious to late crops than forward ones, owing to the great dampness of the ground in autumn.

"For the third crop, after having scuffled, and cleansed the ground well, it must then be ploughed up in the manner denoted above, four inches deep if the staple will permit. And when the seed is to be drilled the ridges should be harrowed twice or thrice in a place, then ten pecks of wheat drilled upon every acre, and finished by harrowing the land once; the less harrowing the better, provided there is depth of mould for permitting the seed to be drilled two inches and a half deep. But when the seed is to be sown broad cast, it should be sown after the land is ploughed, at the rate of twelve pecks to the acre; harrowing the land just enough to cover the seed; then water furrow it, and afterwards grip or drain it completely in both cases."

Where "the stems and foliage of the wheat are too vigorous, it may be advantageous to eat it down with sheep the latter end of March, or beginning of April, and afterwards to harrow it the length way and to roll it the cross way

way of the ridges. And about the latter end of May the wheat should be breast or horse-hoed if drilled; if sown broad cast, the weeding must be done by hand; the same operations should be performed a second time in the month of June."

For the "fourth, or fallow crop, the land should be ploughed across into ridges four inches and a half deep, early in November, and afterwards well water-furrowed, and gripped or drained completely. The field will then lie in deep open furrows and high narrow ridges, and consequently be exposed to the largest extent of superficies that is possible, which is the *sine qua non* of ploughing such land. Sometimes in February, as soon as the season and weather will permit, the ridges must be split down the middle and reversed, so that the whole surface-soil may be equally exposed to the influence of the sun and atmosphere. And about the beginning of April, the ridges should be drawn down by the break or drag-harrow going across them once or twice; after lying in this state some time, the land should get a clean ploughing four inches deep the latter end of the same month. About the middle of May is the last time to lay on the auxiliary earths, *viz.* four chaldrons of lime, or six chaldrons of chalk, or fifty tons of calcareous marl, or four chaldrons of ashes, or twenty cubic yards of tanners' bark, or fifty tons of sand, or fifty tons of peat-earth, &c. upon every acre; then drag-harrow the land both length and crossways to incorporate the whole intimately together. If the land is very rough, it may be reduced a little either by the spike-roller, or a heavyish plain one, to a roundish clod; but it should not by any means be made too fine. When long dung is the intended manure, it should not be laid on till after the second clean ploughing has been given, which should be done the later end of May in both cases: after the middle of June, the dung may be laid on after the rate of ten or twelve tons to the acre; the land in either case must then be ploughed into ridges of from nine to twelve feet wide, and gathered up in the manner described above; then sow half a peck of cole-seed upon every acre, if sown broad cast, or a quarter of a peck, if drilled; and then harrow the whole once. If any weeds spring up, they must be hand-hoed, whether the seed has been drilled or sown broad-cast.

"The cole should be eaten off in the month of September; then plough the land immediately after the cole has been eaten off three inches and a half deep, reserving the furrows, which must be left clear and open for the sake of draining the land in winter; open also all the cross grips or drains completely, so that no water may be suffered to stand upon the land; for to all improvements draining is the first step. As soon as the weather permits, in April, the land must be ploughed, for the last time, into three inches deep furrows, which must be reserved again; reduce the surface to a very fine tilth, by harrowing and rolling it completely for the reception of the seeds. Then upon every acre he advises the sowing the following seeds:"

"*Of artificial Grass-seeds.*

Cow clover, - - - - -	8 pounds.
White ditto, - - - - -	10 ditto.
Trefoil, - - - - -	4 ditto.

"*Of natural Grass-seeds.*

Sweet scented vernal grass, - -	½ peck.
Meadow foxtail grass, - - -	1 ditto.
Rough-stalked meadow grass, - -	1 ditto.
Meadow fescue grass, - - -	½ ditto.
Rye grass, - - - - - -	2 ditto."

This "composition and proportion of seeds are the most suitable for clayey or moist soils, and will form in two or three years a most excellent meadow, as all the plants sown are strong and hardy perennials. After the seeds have been all sown, the land should be bush-harrowed once, the length way of the ridges, and then rolled across."

And "the next thing to be done," he says, "is carefully to open all the water-furrows with a double mould-board plough, four inches deep, no width at bottom, but eight inches wide at top. Then open all the cross grips or main drains in the manner expressed" at *fig.* 2. in the same plate. "Afterwards roll the whole down the cross way of the lands."

It is added, that "no stock should be suffered to graze on the seeds till they have got proper hold of the ground; when that happens, ewes, and lambs, and yearly beasts are the most proper stock for them the first year. And as the act of [illegible] the quantity of leaves round the root of young grass, [illegible] the central stems by them and [illegible] in the [illegible], whence new [illegible] produced [illegible] the first [illegible] of the stem [illegible] it [illegible] way [illegible], which are [illegible] grazed, are so much thicker or closer covered with grass roots, than those which are annually mowed. Hence the impropriety of mowing the grass the first, or even the second, third, or fourth year; especially upon this soil, which produces them very tardily." By the above management, the land will, he thinks, keep one-third more stock than it did for several years. But, after a certain period of time, the grasses degenerate, and the pasture returns to its original state, which, he says, shews the necessity of converting grass land into tillage, and of laying down such lands with grass-seed alternately."

CLAYEY *Loam*, that sort of loam which contains a large proportion of clay in its composition. It is a sort of land that is of the more stiff kind, but which is highly productive when properly cultivated. It abounds much in many districts. See LOAM and SOIL.

CLAYEY *Marl*, that sort of marle which has much of the clayey ingredient in its composition. See MARL.

CLAYEY *Soil*, that sort which is principally constituted of clayey materials. Extensive districts are met with in which the soil is chiefly of this sort. See SOIL.

CLAYING OF LAND, the process of applying this sort of material on land, which, in many cases, is found extremely beneficial in affording a better texture and consistence. In the county of Norfolk the term claying is often improperly applied to the practice of marling.

In many situations, where marl is not to be had, clay may often be found at no great depth below the surface, and may be had recourse to with the greatest benefit on the more light poor sorts of land. See SOIL.

The application of it is a business that may proceed during most of the summer as well as the autumnal months, and often in the winter, with much propriety and convenience; but it is constantly the most advantageously laid on before the commencement of the winter frosts, as in that way it is more perfectly reduced and incorporated with the land. The manner of performing the work is similar to that made use of for marl. See MARLING.

CLAYING *of Sugar.* See SUGAR.

CLAYONAGE, *in the Military Art*, hurdles for covering the wooden work of a gallery for the passage of the ditch, and for securing the people employed in carrying on the saps against the fire of the besieged when it is dangerous.

CLAYTON, THOMAS, in *Biography*, took his degree of doctor in medicine at Oxford towards the end of the seventeenth

teenth century, and soon after went to Virginia, from whence he corresponded with the Royal Society. Several of his communications, treating of the culture and different species of the nicotiana (tobacco), are published in numbers 201, 4, 5, and 6, of the "Philosophical Transactions," and in number 454 is an ample account of medicinal plants which he had discovered growing in that country. Haller supposes that the "Flora Virginica exhibens plantas quas T. Clayton in Virginia observavit et collegit," was composed from papers left by him. It was published by Gronovius, at Leyden, in 1743, 8vo., and again in 4to. in 1762. Haller. Bib. Bot.

CLAYTON, ROBERT, a learned prelate of the church of Ireland, was born in the capital of that kingdom, in 1695. He was the son of Dr. Clayton, minister of St. Michael in that city, and dean of Kildare. He received his classical education at Westminster school; whence he removed to Trinity college, Dublin, of which he was some time after elected a fellow. The date of his first degrees, and of his ordination, are not known, but he became doctor in divinity in 1729. On his father's death, coming into possession of a handsome fortune, he conscientiously resigned his fellowship without any prospect of compensation by church preferment; a measure, it must be confessed, not very usual among members of Universities. But this scrupulous generosity of disposition appears to have been a prominent feature of Dr. Clayton's character; for on his marriage in 1728, he presented the fortune which he received with his wife to her sister; and made a better provision for his own sisters than had been done by his father, by doubling the legacies which he had left them. It was this beneficent temper that led principally to his advancement in his profession. During a temporary residence in London, shortly after his marriage, a person applied to him for pecuniary relief, whose case was recommended by Dr. Samuel Clarke. Dr. Clayton, entering fully into the situation of the petitioner, presented him with a donation of three hundred pounds. This munificent act procured him the acquaintance and the friendship of Dr. Clarke; and it is thought that this intimacy contributed to the heterodoxy which Dr. Clayton afterwards manifested with regard to many of the doctrines of his church. Dr. Clarke took an early opportunity to introduce his friend to queen Caroline, who had already, from the report of his beneficence, entertained a favourable opinion of his character, which was greatly strengthened and confirmed by the kind offices of lady Sundon, a relation of Dr. Clayton by marriage, and at that time a great favourite at court. Under these very favourable auspices, which Dr. Clayton's personal merit gradually secured for him, he obtained the queen's recommendation to the lord lieutenant for the first vacant bishopric in Ireland, and in consequence was presented to the see of Killala in January 1729—30. In November 1735 he was translated to Cork, and to Clogher in 1745. Thus far Clayton had been distinguished rather as the polite gentleman than the erudite scholar and divine; and from his long silence in the literary world, even after his elevation in the church, and his unassuming diffidence upon topics of learned disquisition, so low was the common opinion of his abilities, that the first publication which appeared under his name, "An Introduction to the History of the Jews," was generally attributed to some other hand. This ungrounded prejudice was, however, soon removed by unquestionable evidence that he possessed talents of a superior kind. In 1747 he published in 4to. an elaborate work, entitled, "The Chronology of the Hebrew Bible vindicated, with some Conjectures in Relation to Egypt," &c. In 1749, he pursued his biblical disquisitions, by publishing "A Dissertation on Prophecy," which was followed in 1751 by "An impartial Enquiry into the Time of the Coming of the Messiah, in two Letters to an eminent Jew." In the course of this year was published, in octavo, "An Essay on Spirit, wherein the Doctrine of the Trinity is considered in the Light of Reason and Nature, as well as in the Light in which it was held by the ancient Hebrews, &c." This work, as may naturally be supposed from its title, excited much attention. In consequence of the bishop of Clogher having prefixed a dedication to it, addressed to the primate of Ireland, and subscribed with his name, he was universally considered as the author, and all the odium which it excited by the supposed heresy of its tenets, was thrown upon him, so as to place an inseparable bar in his way to farther ecclesiastical promotion. In fact, however, the bishop was only its foster father, the work having been written, as afterwards appeared, by a young clergyman of his diocese, who was too strongly apprehensive of the consequences to bring it forward under his own name. The alarm spread by this publication among the clergy may be estimated by the number of pamphlets to which it gave occasion. The controversy to which it prompted was not, however, marked by any display of superior talent and erudition. Dr. Clayton next appeared before the public in a work universally allowed to be his legitimate production; it was entitled, "A Vindication of the Histories of the Old and New Testament, in Answer to the Objections of the late lord Bolingbroke, in two Letters to a young Nobleman." It was published in octavo, 1752. This was only the first part of an extensive design, which Dr. Clayton afterwards prosecuted; for in 1754, he published "A second Part, wherein the Mosaical History of the Creation and Deluge is philosophically explained, the Errors of the present Theory of the Tides detected and rectified, &c." There is much ingenuity and learning displayed in these works; but many of the remarks discover a deficiency of judgment, and a mind too much swayed by hypothetical fancies. In the interval between the publication of these two pieces, Dr. Clayton published a translation of "A Journal from Grand Cairo to Mount Sinai and back again; from a Manuscript written by the Prefetto of Egypt, in Company with the Missionaries *de propaganda Fide* at Grand Cairo. To which are added, some Remarks on the Origin of Hieroglyphics and the Mythology of the ancient Heathens." The principal object of the bishop in the translation and publication of this work, was to recommend to the attention of the Society of Antiquaries certain ancient inscriptions which are mentioned in it, as existing in a part of the wilderness of Sinai, known by the name of the *Written Mountains*, and from which his lordship conceived that it might be possible to recover the ancient Hebrew character. The society did not, however, second his views, notwithstanding his munificent offer of assistance to defray the expences which might attend the experiment. Nor do his lordship's conjectures appear to have been well founded, for when Mr. Edward Wortley Montague afterwards visited the very spot where such important discoveries were expected to be made, he was grievously disappointed by finding the inscriptions intermixed every where with representations of human figures, which clearly demonstrated that they were not the work of any of the descendants of Jacob. The bishop published, in 1755, a correspondence which had passed between him and Mr. William Penn on the subject of baptism. The next year was marked by a bold attempt on the part of his lordship to introduce some material innovation into the liturgy of the established church. He had in his writings expressed his disapprobation of the Athanasian and Nicene creeds; and, prompted by his wish to have them expunged, he determined ed to bring the matter to a fair difcuffion, by introducing the fubject in the form of a motion to the Irifh Houfe of Lords, which he did on the 2d of Fe&ruary, 1756, by moving, That thofe creeds fhould, for the future, be left out of the liturgy of the Church of Ireland. The fpeech which he delivered on this occafion was afterwards publifhed, and paffed through feveral editions. Dr. Clayton's conduct and fentiments on this occafion gave very general offence to his ecclefiaftical brethren, and created him a holt of powerful enemies. Great, however, as was the outcry raifed againft him, no fteps of a public nature were taken to arraign his conduct, until the appearance of the third part of the "Vindication of the Hiftory of the Old and New Teftament" in 1757, in which, unappalled by the formidable afpect of his adverfaries, he purfued his fpeculations even farther than he had before done. But his prefent attack was deemed by his more orthodox ecclefiaftical fuperiors and brethren to be of fo hoftile a complexion, that they came to a refolution to make his proceedings the fubject of legal inquiry. Under their influence, his majefty, George the Second, directed the duke of Bedford, then lord lieutenant of Ireland, to inftitute a profecution againft the bifhop of Clogher. Agreeably to this, a day was fixed for a general meeting of the Irifh prelates at the houfe of the primate, and Dr. Clayton was fummoned to attend. Before, however, the time arrived, an end was put to their malicious proceedings, by the death of the venerable object of their enmity and perfecution. The thought that he was abandoned by the king, from whom, as placed above the influence of the paltry animofities by which his fubjects may often be divided, he had hoped for fhelter and protection in the gathering ftorm, joined to his repugnance, to have paffed againft him a verdict of cenfure or deprivation, is thought to have affected his fpirits fo deeply, as to bring on an obftinate nervous fever, of which he died, February 26th, 1758, in the 64th year of his age. Biog. Brit.

Clayton, Thomas, an Englifh mufician, and one of the royal band in the reign of king William and queen Mary, who having been in Italy, had not only perfuaded himfelf, but had the addrefs to perfuade others, that he was equal to the tafk of reforming our tafte in mufic, and eftablifhing operas in our own language, not inferior to thofe which were then fo much admired on the Continent. And the firft mufical drama that was wholly performed after the Italian manner, in recitative for the dialogue or narrative parts, and meafured melody for the airs, was "Arfinoe Queen of Cyprus," tranflated from an Italian opera of the fame name, written by Stanzani of Bologna, for that theatre, in 1677, and revived at Venice 1678. And the Englifh verfion of this opera, fet by Clayton, was our firft attempt at a mufical drama after the manner of the Italians, with recitative in the dialogue, inftead of declamation. In the compofer's preface to the printed copy of the words, he fays, that "the defign of this entertainment being to introduce the Italian manner of mufic on the Englifh ftage, which has not been before attempted, I was obliged to have an Italian opera tranflated: in which the words, however mean in feveral places, fuited much better with that manner of mufic, than others more poetical would do. The ftyle of this mufic is to exprefs the paffions, which is the foul of mufic; and though the voices are not equal to the Italian, yet I have engaged the beft that were to be found in England; and I have not been wanting, to the utmoft of my diligence, in the inftructing of them. The mufic being recitative, may not, at firft, meet with that general acception, as is to be hoped for, from the audience's being better acquainted with it: but if this attempt fhall be a means of bringing this manner of mufic to be ufed in my native country, I fhall think my ftudy and pains very well employed."

The fingers were all Englifh, confifting of Meffrs. Hughes, Leveridge, and Cook; with Mrs. Tofts, Mrs. Crofs, and Mr. Lyndfey. This opera was firft performed at Drury-lane, January 16th, by fubfcription; the pit and boxes were referved for fubfcribers, the reft of the theatre was open as ufual, at the fubfcription mufic. In the Daily Courant, Arfinoe is called "a new opera, after the Italian manner, all fung, being fet by mafter Clayton, with dancing and finging before and after the opera, by fignora F. Margarita de l'Epine." This finging was probably in Italian.

Clayton is fuppofed to have brought from Italy a collection of the favourite opera airs of the time, from which he pillaged paffages and adapted them to Englifh words; but this is doing the mufic of Arfinoe too much honour. In the title-page of the mufic, printed by Walfh, we are affured that it was wholly compofed by Mr. Thomas Clayton; and in juftice to the mafters of Italy at that time, it may be allowed to be his own, as nothing fo mean in melody and incorrect in counterpoint was likely to have been produced by any of the reigning compofers of that time. For not only the common rules of mufical compofition are violated in every fong, but the profody and accents of our language. The tranflation is wretched; but it is rendered much more abfurd by the manner in which it is fet to mufic. Indeed, the Englifh muft have hungered and thirfted extremely after dramatic mufic at this time, to be attracted and amufed by fuch trafh. It is fcarcely credible, that in the courfe of the firft year this miferable performance, which neither deferved the name of a *drama* by its poetry, nor an *opera* by its mufic, fhould fuftain twenty-four reprefentations, and the fecond year eleven.

But fuch was now the paffion for this exotic fpecies of amufement, even in its lifping infant ftate, that the perfpicacious critic and zealous patriot, Mr. Addifon, condefcended to write an opera for the fame Englifh fingers as had been employed in Arfinoe. Mr. Addifon, though he had vifited Italy, and was always ambitious of being thought a judge of mufic, difcovers, whenever he mentions the fubject, a total want of fenfibility as well as knowledge in the art. But this admirable writer and refpectable critic in topics within his competence, never manifefted a greater want of tafte and intelligence in mufic than when he employed Clayton to fet his opera of Rofamond. Indeed, it feems as if nothing but the groffeft ignorance, or defect of ear, could be impofed upon by the pretenfions of fo fhallow and contemptible a compofer. But, to judges of mufic, nothing more need be faid of Mr. Addifon's abilities to decide concerning the comparative degrees of national excellence in the art, and the merit of particular mafters, than his predilection for the productions of Clayton, and infenfibility to the force and originality of Handel's compofitions in Rinaldo, with which every real judge and lover of mufic feem to have been captivated.

This opera, in fpite of all its poetical merit, and the partiality of a confiderable part of the nation for Englifh mufic and Englifh finging, as well as fervent wifh to eftablifh this elegant fpecies of mufic in our own country without the affiftance of foreigners, after fupporting with great difficulty only three reprefentations, was laid afide and never again performed to the fame mufic.

In the year 1733, this Englifh drama was fet, as a *coup d'effai*, by Mr. Thomas Aug. Arne, afterwards Dr. Arne, and performed at the little theatre in the Haymarket; in which his fifter Mifs Arne, afterwards Mrs. Cibber, performed

formed the part of Rosamond; that admirable actress appearing first on the stage in this character as a singer. The three following airs were admirably set, and remained long in favour: "No, no, 'tis decreed,"—"Was ever nymph like Rosamond," and "Rise glory, rise." See OPERA and ADDISON.

CLAYTONIA, in *Botany*, (named from John Clayton, who collected plants, chiefly in Virginia, for Gronovius, which were published by him in his "Flora Virginica.) Linn. Gen. 287. Schreb. 402. Gært. 745. Juss. 314. Vent. 3. 260. Lam. Ill. 394. Class and Order, *pentandria monogynia*. Nat. Ord. *Succulentæ*, Linn. *Portulaceæ*, Juss. Vent.

Gen. Ch. *Cal.* two-leaved, persisting; leaves egg-shaped, rather acute, opposite. *Cor.* Petals five, egg-shaped or oblong, obtuse, narrowed at the base, longer than the calyx. *Stam.* Filaments five, awl-shaped, a little shorter than the corolla, affixed to the claws of the petals; anthers oblong, incumbent. *Pist.* Germ superior, roundish; style simple, the length of the stamens; stigma trifid. *Peric.* Capsule egg-shaped, one-celled, three-valved, included in the calyx. *Seeds* three, roundish.

Eff. Ch. Calyx two-celled. Petals five. Stigma three-cleft. Capsule one-celled, three-valved, three-seeded.

Sp. 1. C. *virginica*, Linn. Sp. 1. Mart. 1. Lam. 2. Pl. 144. fig. 1. Willd. 1. Gron. Virg. 25. Bot. Mag. 941. (Ornithogalo affinis virginiana; Pluk. Alm. tab. 102. fig. 3. Rudb. Elys. 2. p. 139. fig. 6.) "Leaves linear-lanceolate, petals entire." *Root* small, tuberous. *Stems* about three inches high, slender. *Root leaves* narrow-linear, almost gramineous. *Stem-leaves* generally two, opposite, linear, green, smooth, a little fleshy. *Flowers* white, spotted or streaked with red on the inside, in a loose terminal raceme. A native of Virginia, flowering in April. There is a variety with lanceolate leaves, and acutish calyxes. 2. C. *sibirica*, Linn. Sp. 2. Mart. 2. Lam. 2. Willd. 2. Gmel. Sib. 4. p. 89. Gært. tab. 129. fig. 3. (Limnia, Linn. Act. Ups. 1746. tab. 5. Act. Holm. 1746. tab. 5.) "Leaves nerved, root and stem ones egg-shaped; petioles trifid," Willd. *Root* tuberous. *Stem* declining. *Root-leaves* petioled, quite smooth. *Stem leaves* two, opposite, sessile. *Flowers* red, racemes two, unilateral, one of them two-leaved. A native of Siberia. 3. C. *perfoliata*, Willd. 3. Donn. Hort. Cant. p. 25. "Leaves without nerves, root ones rhomb-egg-shaped, stem ones somewhat connate; flowers umbel-verticillate; petals entire," Willd. *Root* annual. *Stem* four or five inches high, erect. *Root-leaves* petioled, somewhat fleshy. *Stem* ones two, opposite; either rhomb-egg-shaped, attenuated, cohering; or egg-shaped, connate on one side, emarginate on the other. *Flowers* white, two or three about the middle of the stem, peduncled, each of them supported by a small oblong bracte; six or eight in a terminal umbel, peduncled, without bractes. A native of North America.

C. *portulacaria*. See PORTULACARIA.

CLAZOMENÆ, in *Ancient Geography*, a town of Asia Minor, and one of the 12 Ionian cities situated in Lydia. Herodotus, who mentions it, assigns it in one place to Ionia, and in another to Lydia. The ancient city stood on the continent, and was fortified by the Ionians at a great expence, in order to put a stop to the Persian conquests. But, after the defeat of Crœsus, and the surrender of Sardis, the inhabitants were so terrified, that they abandoned the city, and withdrew, with all their effects, to one of the neighbouring islands, where they built the city of Clazomenæ, so often mentioned in the Roman history. Pausanias (Achaic. c. 3.) informs us, that Alexander joined it to the continent by a causeway 250 paces long; whence Strabo, Pliny, Ptolemy, and most of the ancient geographers, count it among the cities on the continent. The Romans, according to Livy, (lib. xxxviii. c. 39.) always treated the inhabitants with great kindness, apprized of the importance of this city to their conquests in Asia; for they not only declared them a free people, but put them in possession of the island of Drymusa, and often quarrelled with the princes of Asia on their account. Augustus repaired and embellished their city with many magnificent buildings; whence, on some medals, he is styled the founder of Clazomenæ, though this city was undoubtedly founded by the Ionians, and from the beginning was one of the Ionian confederacy. Some antiquarians take Clazomenæ for the ancient city of Grynium, which gave the epithet of Grynæus to Apollo; for, in ancient times, Apollo had a famous temple in the vicinity of Clazomenæ. Cybele was likewise one of their chief deities, and also Diana, as we learn from several ancient medals and inscriptions. The Clazomenians held out against the Lydians, after most of the other cities of Ionia were reduced by Alyattes, who besieged, but could not master Clazomenæ. The Persians gained possession of it in the time of Darius Hystaspis, and such was its importance in their estimation, that they would not part with it at the famous peace of Antalcides. Alexander reinstated them in their ancient liberty and privileges; which were enlarged by the Romans, whom they assisted on all occasions with great fidelity. Clazomenæ anciently derived great profit from its oils. On one occasion its inhabitants had recourse to a singular contrivance for restoring their finances. After a war that had exhausted the public treasury, they found themselves indebted to the disbanded soldiers to the amount of 20 talents (4,500 *l*); which, being unable to raise, they paid them, during some years, interest, which they fixed at 5 *per cent.* They afterwards struck copper money, to which they affixed the same value as if it were silver. The rich consented to take it: the debt was liquidated, and the revenues of the state administered with economy, enabled them gradually to call in the adulterated coin circulated in commerce. The ancient Clazomenæ was the native place of Anaxagoras. On or near the ruins of this illustrious city, was built the present *Dourlak*, or *Vourla*, a small town, situated on the south coast of the gulf of Smyrna.

CLEAN *Lough*, in *Geography*, a small lake of the county of Leitrim, Ireland, which is considered as the fountain of the noble river Shannon. This lake is not four miles distant from the river Bonnet, which carries boats into Lough Gilly, and thence into Sligo bay. Perhaps, says Dr. Beaufort, the day may come, when the spirit of enterprize and commerce will open itself a passage by this channel.—Beaufort.

CLEANDRIA, in *Ancient Geography*, a place of Asia Minor, in the Troade, where Strabo places the source of the Rhodius.

CLEANTHES, in *Biography*, a stoic philosopher, and a disciple of Zeno, was born in the year 339 B. C. and died in 240 B. C. He wrote many pieces, none of which are come down to us, except his "Hymn to Jupiter," and a few fragments; the several editions of which have been enumerated, with the various readings, and critical remarks, by the learned reviewer of Butler's edition of "Marcus Musurus," &c. containing this hymn, and other fragments, (Monthly Review, enlarged, vol. xxv, p. 18, &c.) It was first published by Fulvius Ursinus, in 1568; then by Henry Stephens, in his "Poesis Philosophica," in 1573; afterwards by Cudworth, in his "Intellectual system," fol. 1678; again in Mosheim's Latin translation of Cudworth, in 1733; a fifth time in the third dissertation added to Daniel Secundum Septuaginta, Rom. fol. 1773; a sixth

time

time in the 2d edition of Mosheim's translation of Cudworth, published after his death, Leyd. Bat. fol. 1773; again in Brunck's "Analecta," in 1776, and afterwards by Brunck, in his edition of the "Gnomici Poetæ;" a ninth time in the "Eclogæ Physicæ" of John Stobæus, published at Gottingen, 8vo. 1792, by A. H. Heeren. It has also been translated into German, Latin, and English. For the English translation by Mr. West, at the desire of a friend, who was pleased to find such just sentiments of the deity in a Heathen, and so much poetry in a philosopher; see "Odes of Pindar," &c. vol. ii.

CLEANTHES, one of the first inventors of painting in Corinth. He is said to have learned the art from Ardices, his countryman, and was one of those painters who were styled monochromatists, because their art extended no farther than to draw the simple outline of the figure, and fill it up with one colour only. Strabo, however, describes some large compositions of this master. Winkelman. Orlandi. Della Valle, Vite d'Pitt. Ant.

CLEAR, in *Building*, is sometimes used among the workmen for the inside work of a house, &c.

CLEAR, in *Sea Language*, is applied to the weather, when it is fair and open; to the coast, when the navigation is not interrupted by rocks, &c. to the cordage, cables, &c. when they are disentangled so as to be ready for immediate service. In these senses it is opposed to foul.

CLEAR, *Cape*, in *Geography*, in the island of Clare south of the county of Cork, the most southern point of land in Ireland. N. lat. 51° 19'. W. long. 9° 24'.

CLEAR *lake*, a lake in the N.W. part of North America, connected with the Athabasca lake by the river Hay, and with the Peace river by the river Pine. See ATHABASCA.

CLEARE, St. a village in Cornwall, being a vicarage in the West Hundred; the situation of the steeple of its church was determined in the government trigonometrical survey in 1796, by an observation from Bindown station, distant 35,256 feet; and another from Kitt Hill station distant 42,931 feet, and bearing 74° 42' 9" N.E. from the parallel to the meridian of Butterton station; whence is deduced its latitude 50° 29' 16" N. and its longitude from Greenwich 4° 27' 20".6 W. or 17^m 49^s.4 in time. In 1777 the Liskeard canal was in contemplation to terminate at Bark-Mill bridge in this parish, for bringing up lime and sea sand for manures, coals, &c. and exporting corn, &c.; but the same has not been carried into effect. See CANAL.

CLEARER, a tool used in *Rope-making*, similar to the hatchell, but with finer teeth, as the hemp is always finished on it for linen and twines for sail-makers, &c.

CLEARING, in *Agriculture*, a term sometimes applied, in threshing corn, to signify a heap large enough to be winnowed.

CLEARING *the Anchor* and *the Hawse*. See ANCHOR and HAWSE.

CLEARING *of Land*, in *Agriculture*, the removing of such obstacles and impediments as retard or prevent its cultivation and improvement. See *Removing Obstructions to* TILLAGE.

CLEARING of *Liquors*. See CLARIFICATION.

CLEAS, in *Agriculture*, a provincial word, signifying the hoofs or claws of cattle, sheep, hogs, &c.

CLEATS, in *Ship building*, are pieces of wood of different shapes, used for various purposes in mast-making, block-making, and rigging. Those used for stopping of shores are commonly made of elm, similar to wedges, but only taper from one side; those for stopping of rigging are haunched on the back with a hollow, from one-third of the length, the thin end being shaped with a duck's bill; these are made of oak; but, for mast-heads, of elm. Cleats used in block-making are made of oak plank or board, and when sawed to different shapes for the purposes to which they are to be applied, they are made smooth, and finished with gouges, chissels, and rasps. In rigging they are used for stops, and ropes are fastened to them. *Arm* or *sling cleats* are nailed on each side of the slings of the lower yard, and have an arm at one end, which lies over the straps of the jeer-blocks, to prevent their being chaffed; these are made of elm-plank, in length one and a quarter of the diameter of the yard, in breadth one-fourth of the length, and in thickness two-thirds of the breadth; the shoulder is one-third of the length of the cleat, and hollowed on the back from the shoulder to the end. *Belaying-cleats* are shaped like range-cleats, but smaller; they have two arms or horns, and are nailed through the middle to the masts, or elsewhere, and to them ropes are belayed. *Comb-cleats* are made of ash, or elm, board; they are semicircular, with their backs rounded so as to resemble a cock's comb, and they have one or more hollow cavities gouged in the middle for the purpose of confining a rope to one place. *Range-cleats* to which are belayed tacks and sheets, are from three to seven inches thick, and in length seven times the thickness. The arms are each one third of the length, and made round; the middle, between the two arms, is left square, twice the thickness in breadth, through which it is bolted or fastened; the back is curved in the length, that the arms may rise from the inside straight. *Shroud cleats* are similar to belaying-cleats, with the addition of an inside piece, out of the same solid, long enough to have a score on each side of the middle part of the cleat, to contain the seizings which fasten it to the shroud; the inside is hollowed to fit the shroud, and another score cut across the middle of the cleat for the middle seizing; the scores are rounded on the outside edges, and cut deep enough to bury the seizing, in order to prevent its being worn when the rope is belayed. *Sling-cleats* are made of elm-plank, in length one and a quarter of the diameter of the yard, in breadth one-fourth of the length, and in thickness two-thirds of the breadth. The shoulder is to be one-third of the length of the cleat, and hollowed on the back from the shoulder to the end; these are used as stops to the straps of jeer-blocks, &c. to the lower yards. *Stop-cleats* are made of oak plank or board, of all lengths under twelve inches; the largest are commonly for gammoning bowsprits and as stops to stay collars. The breadth is one-fourth of the length, the thickness two-thirds of the breadth, and they are hollowed on the back. Those for lashings on the mast-heads are made of elm, three times the thickness in breadth, and one and a half of the breadth in length. Stop cleats are nailed to the yard-arms, to prevent the slipping of the rigging and the gammoning, &c. *Thumb-cleats* are similar in shape to arm-cleats, but are much smaller; they are nailed up vertically to hang any thing on; or horizontally, as stop-cleats. Cleats are nailed wherever they are wanted with more or fewer nails, according to the strain they resist.

CLEAVERS, or CLIVERS, in *Botany*. See GALIUM *Aparine*.

CLEBUCZ, in *Geography*, a town of European Turkey, in Dalmatia; 11 miles S.S.E. of Moster.

CLEBURG, a town of Germany with a castle, in the circle of the Upper Rhine, and duchy of Deux Ponts, which gives name to a branch of the Palatine family; 28 miles S.S.W. of Deux Ponts.

CLEBURY. See CLEOBURY.

CLECHE', or CLECHY, a French term in *Heraldry*, signifying any ordinary or bearing that is pierced throughout, *i. e.* when the whole figure is so much perforated that the chief which substance is taken from it, and nothing remains visible but the edges.

CLECY, in *Geography*, a town of France in the department of Calvados, and district of Falaise; containing about 1700 inhabitants; 3½ leagues W. of Falaise.

CLEDAGH, the name of several rivers in Wales; one runs into the Usk in Monmouthshire; another runs into the river of Neath, 5 miles N. of Neath in Glamorganshire; a third runs into the Muthvey, 2 miles E. of Langadock in Caermarthenshire; and a fourth runs into the Clethy in Pembrokeshire.

CLEDAGNVAGH, a river of Wales, which runs into the Usk, about a mile W. of Abergavenny.

CLEDEN, a town of France, in the department of Finisterre, and district of Quimper; 2 leagues W. of Pontcroix.—Also, a town in the same department, and district of Morlaix; 1½ league W. of St. Pol-de Leon.—Also, a town in the same department and district of Chateaulun; 5 miles S.W. of Carhaix.

CLEDGE, a name given by miners to the upper part of the stratum of fuller's earth.

CLEDGY, in *Agriculture*, a term applied to such kinds of land as are stiff, stubborn, and of a hard tenacious quality, from the mixture of clay in them.

CLEDHEWEN, a river of Wales, which runs into the Dungledy, in Pembrokeshire.

CLEDONISM, CLEDONISMUS, a kind of divination in use among the ancients.

The word is formed from κληδων, which signifies two things, *rumor*, a report, and *avis*, a bird: in the first sense *kledonism* should denote a kind of divination drawn from words occasionally uttered. Cicero observes, that the Pythagoreans made observation not only of the words of the gods, but of those of men; and accordingly, believed the pronouncing of certain words, *v. g. incendium*, at a meal, very unhappy. Thus, instead of prison, they used the word *domicilium*; and to avoid *erinnyes*, furies, said *eumenides*.

In the second sense, cledonism should seem to be a divination drawn from birds: the same with ornithomantia.

CLEEF, JOAS, or JOOST VAN, in *Biography*, a painter, native of Antwerp, who enjoyed the reputation of being one of the best colourists of his time. The period of his birth is not known, but it appears that he entered into the company of painters at Antwerp, in the year 1511.

Soon after the marriage of Philip of Spain to Mary queen of England, he came to London; but seeing some pictures of Titian preferred to his own, he became frantic with rage and disappointment, and from that time was nick-named Joost the Madman. There was an altar picture by him at the church of Notre Dame at Antwerp, which is said to have possessed much of the purity of the Roman school of painting: the subject was S. Cosmo and Damiano. The period when this artist died is unknown. Descamps. Heinecken. Pilkington.

CLEEF, HENDRICK, HENRY, MARTIN, and WILLEM VAN, three brothers, painters of Antwerp; the first, HENDRICK, excelled in landscape, and having spent many years in studying at Rome, published upon his return many views of the ruins of ancient temples existing in that city. He was received into the company of painters at Antwerp in 1533, and died in 1589. MARTIN, the second brother, was the disciple of Francis Floris, and was admired for his history pieces with small figures. Many landscape painters, and amongst others Gillis Coninxloo employed him to paint the figures in their landscapes. He became one of the company of painters at Antwerp in 1551, and died aged 50. WILLEM, the other brother, excelled in large figure painting, but died young. Martin had four sons, all painters, Gillis, Martin, George, and Nicolas. The first painted well in small, but died young; the second lived a long time in Spain, and afterwards went to the Indies: Nicolas was still living at Antwerp in the time of Van Mander, in the year 1604. According to Strutt and Heinecken, Henry and Martin Van Cleef engraved a few pieces. Descamps. Heinecken.

CLEEF, JOHN VAN, a Flemish painter of considerable note, was born at Venloo, in 1646, and having discovered, when young, a strong inclination for the art, was placed under the tuition of Gentile, an historical painter at Brussels, with whom, however, he remained but a short time: he then became a disciple of Gaspar de Crayer, to whom he was so much attached, that he continued with him until his death; when he was judged capable to put the last hand to some designs left unfinished by Gaspar, particularly the cartoons for the tapestry intended for Lewis XIV.

He had a manner peculiar to himself, and in composition and design far surpassed his master, though he fell short of him in colouring. His pencil was bold and flowing: his pictures, though full of figures, are free from confusion; and he thoroughly understood the introduction of architectural decoration.

He painted the principal altar-pieces of Ghent, many of which are described by his historian, Descamps. Amongst the most celebrated is a large picture at the church of St. James, representing Christ delivering the Souls out of Prison; and another in the church of a convent, where the Nuns are relieving those afflicted with the Plague; the Virgin and Child, S. Austin, S. Catherine, and other saints, are seen in the sky. This artist died in the year 1716, aged 70. Descamps.

CLEENISH, in *Geography*, a small island in Lough Erne, county of Fermanagh, Ireland, about three miles from Enniskillen.

CLEES, LES, or LES ESCLEES, a town of Swisserland, in the canton of Berne, seated on the Orbe, in the road to France; 8 miles S.W. of Yverdun.

CLEETA, in *Biography*, an ancient Greek architect and sculptor. He built the Palæstra, or large court near Olympius, used for the horse and chariot races at the celebrated Olympic games, which were held in this place at the close of every olympiad, that is every fifth year. It was magnificently decorated with porticoes and other ornaments, and the author was so proud of his performance, that he introduced the following inscription under one of the statues which he had made at Athens; "Cleeta, the son of Aristocles, who invented the Palæstra of Olympius, did this." Milizia. Mem. degli Arch.

CLEF, (from *clavis*, Lat. and κλεις, Gr. *a key*), a character in *Music* to denote what part of the general scale the sounds before which it is placed are to be sung or played. Previous to the time of pope Gregory, to whom the square and lozenge notes used in canto fermo are ascribed, and which are now best known by the name of *Gregorian notes*, there were various methods of pointing out the elevation and depression of the voice in chanting the mass, not only before the time-table was formed, but even before lines and spaces were used. These indications of change of voice were placed over the words long before a single line ascertained the difference of their situation. This was followed by a 2d, a 3d, and a 4th line, to which, with the spaces, canto fermo, in Roman missals, is still limited.

The names and examples of all the first characters used for the modulation of voice may be seen in the General History of Music, vol. ii. from p. 33 to 55.

After lines had increased to 8, in the 10th century, only the

the ſpaces were uſed, not for the notes, but ſyllables, the notes being placed in a kind of frame, on the left ſide, one to each ſyllable of the words. After this an alphabetic character was placed at the beginning of each line, capitals for the grave ſounds, and minuſcules for the acute. To this kind of notation *points* ſucceeded. Padre Martini has given three examples of only one line, to regulate the points uſed as notes over the words, a red line for the key of F, and a yellow one for that of C. This ſeems the origin of clefs, which are only Gothic letters corrupted.

Vincenzio Galilei (Dial. della Muſ. Ant. e Mod. p. 36.) ſays, that a little before the time of Guido the points were placed on ſeven lines only, without uſing the ſpaces; perhaps in imitation of the ſeven ſtrings of the ancient lyre.

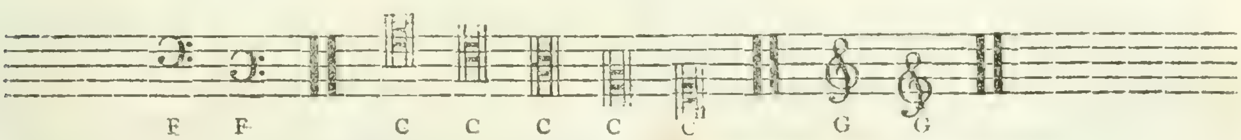
Few, however, of theſe methods of notation ſeem to have been generally received in contemporary miſſals, after the Greek characters were diſuſed; for in the MS. ſpecimens which we have ſeen, the marks placed over the words, in the middle ages, previous to the time of Guido, often appear arbitrary, and to have been adopted only in ſome particular church, convent, or fraternity.

The ſinging clefs, or *claves ſignatæ* of the middle ages, were nothing but a c, a g, or an F, placed on one of the four lines uſed in canto fermo, as thus, 
Having traced the origin of clefs from ancient MSS., and the progreſſive improvements in ſimplifying them in proportion as the muſical art became more complicated, we ſhall waſte no time or paper in deſcribing new ſchemes of notation, and expedients for diminiſhing or augmenting the number of clefs in preſent uſe, but proceed to exhibit their form and explain their practical uſe in the moſt preciſe and clear manner we are able, without deviating from the method in which they have long been taught by the moſt learned, intelligent, and experienced muſicians, who have ſubmitted to the drudgery of inſtructing, not only pupils who receive pleaſure from the ſkill of others, and wiſh to entertain themſelves, but even thoſe on whom it is forced, and who having neither ear nor inclination for muſic, dread the ſight of a maſter, and regard him in no better light than a perſecutor.

The *tenor clef*, that ſtumbling block to the idle and liſtleſs, would be as legible as the treble or baſe, if learned in the ſame manner, and the pupils were accuſtomed to play favourite airs in all kinds of tenor clefs, and tranſpoſe by them early in their ſtudies. The printing new editions of old authors of organ and harpſichord pieces, without the admiſſion of tenor clefs, is a miſchievous indulgence, which having precluded the trouble of learning theſe clefs, renders all the old editions of the beſt authors of the laſt century unintelligible; as it does all the muſic in ſcore written or printed abroad; all vocal muſic from Italy, and harpſichord leſſons from Germany compoſed 20 or 30 years ago; all the works of Sebaſtian Bach, and the early productions of his admirable ſon, Emanuel, for the harpſichord, of which the treble or right-hand part is in the ſoprano clef, or tenor on the firſt line. Theſe, however excellent, are become totally obſolete and illegible to all but regular bred profeſſors, in our country only.

Three clefs, removeable from time to time, include the whole ſyſtem of muſical ſounds. Theſe are denominated Base, Tenor, and Treble.

It is to be remembered that theſe ſeveral clefs are always placed on a line at the beginning of the five-line ſtaff, never on a ſpace; and though removeable, always retaining the power of giving the name of F, C, or G, to whatever line they are removed: as the baſe clef makes every line on which it is placed F; the tenor C; and the treble G.

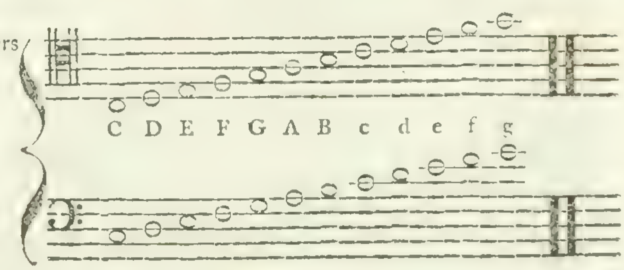


Now as theſe clefs have different appellations to diſtinguiſh them from each other, we ſhall give a gammut of thoſe leaſt in uſe, as a kind of dictionary, with equivalent ſounds in the two well-known clefs of G and F, to explain them.

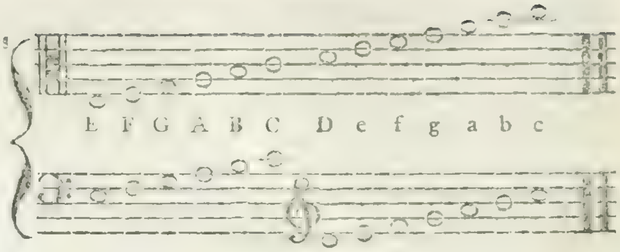
The baſe clef on the 3d line is called the *baritono clef*, and is 3 notes higher than the common baſe clef on the 4th line.

The tenor clef on the 5th line is equivalent to the baſe clef on the 3d line, and in old muſic, theſe two clefs are uſed promiſcuouſly.

Alto tenore, or high tenor clef on the 4th line, renders ſounds 5 notes higher than the baſe.

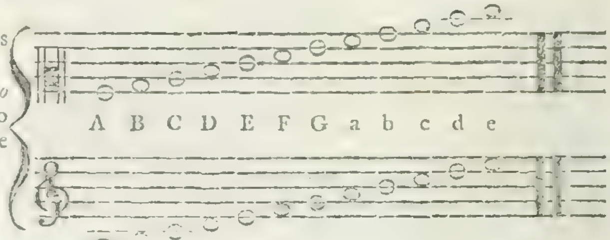


Contralto, or counter-tenor clef on the 3d line, 7 notes lower than the treble, and 7 notes higher than the base.



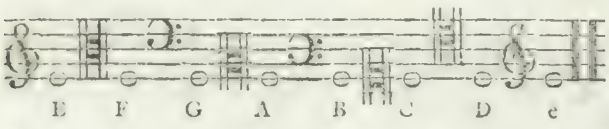
The *mezzo soprano*, or second treble clef on the 2d line, is 5 notes lower than the treble.

This clef is now seldom used; but in Purcell's time the *alto viola*, or instrumental-tenor part, was written in the mezzo soprano clef, which was the custom in France till the middle of the last century.

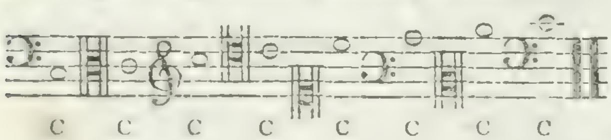


Soprano, or supreme clef, in which all treble voice-parts are composed in Italy and Germany, is the tenor clef on the first line, and renders every sound a 3d lower than the treble.

Dr. Pepusch, after giving his pupils a regular scale in each clef, made them familiarize themselves to the changes which they occasioned in the names of the notes and in their situation on the staff, by written exercises, giving them a series of 8 or more notes on the same line or space, and obliging them to find a clef for every note which will make it ascend or descend one degree, as thus:



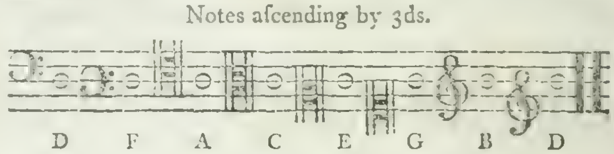
or, though seeming to ascend, remaining stationary,



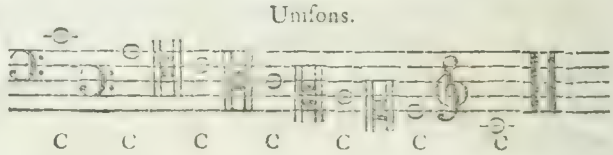
This method was recommended by Mr. Galliard, in his translation of "Tosi's Observations on florid Song," Pl. No. 2. p. 17. pointing out its utility in transposition. But he was not the first who suggested this expedient; we find it in "Cerone della Musica," p. 515. a work in Spanish, published at Venice 1614. See TRANSPOSITION.

Rousseau (Dict. de Mus.) has adopted the same method, and given in *Plate* A, *fig*. 4 and 8, the two following examples.

Notes ascending by 3ds.



Unisons.



CLEF *de mousquet, de carabine, de pistolet, d'arquebuse à rouet*, the spanner or lock of a musquet, carabine, &c.

CLEFMONT, in *Geography*, a town of France, in the department of the Upper Marne, and chief place of a canton in the district of Chaumont; 17 miles S. of Bourmont. The place contains 380, and the canton 6996 inhabitants; the territory includes 180 kiliometres and 21 communes.

CLEFS, a town of France, in the department of the Maine and Loire, and district of Baugé, 2 leagues N. of it.

CLEFS *d'une ville ou place de guerre*, the keys of all the gates of a strong place, as a fort, citadel, castle, town, or city of war, which an officer is charged with carrying every evening after the

the ſhutting of the gates, to the governor, or the perſon who commands in his abſence. The magazines, which contain pieces of artillery, are locked under three keys; one of which is carried to the commandant of the place, the ſecond to the commiſſary of artillery, and the third remains in the hands of the perſon who has charge of the magazine.

CLEFT, in *Grafting*. See Engrafting.

CLEFTS, or Cracks, in the heels of horſes, are occaſioned by hard labour, unwholeſome food, want of exerciſe, and waſhing them when hot. They are cured by cutting off the hair, and anointing with the oil of hemp-ſeed or linſeed, and keeping them clean.

CLEGG, John, in *Biography*, a pupil of Dubourg on the violin, who travelled into Italy with Lord Ferrers, where he improved himſelf ſo much, that, on his return in 1723, he excelled in force and execution every performer in England, till the year 1742, when he had ſo deranged his faculties by intenſe ſtudy and practice, that he was confined in the hoſpital of Bedlam; where, during intervals of ſanity, he was allowed the uſe of his inſtrument; and it was long a faſhionable, though inhuman, amuſement, to viſit him there, among other lunatics, in hopes of being entertained by his fiddle or his folly. He was long the ſubject of praiſe, and regarded as a young man of ſuch ſuperior genius and abilities, that no one who had ever heard him would allow that he was equalled by any performer, on the ſame inſtrument, in Europe.

CLEGHORN, George, a diſtinguiſhed practitioner in medicine, was born at Granton, near Edinburgh, in December 1716. Shewing early an inclination to the ſtudy of medicine he was ſent to Edinburgh, and placed under the tuition of Dr. Alexander Monroe. While there he became acquainted with Dr. Fothergill, by whom he was materially aſſiſted in his ſtudies. In the year 1736 he was appointed ſurgeon to the 22d regiment of foot, then ſtationed in the iſland of Minorca, where he continued thirteen years. During his reſidence in this iſland, he employed his leiſure time in diſſecting monkeys and other animals, with which the place abounded; he alſo examined and acquired a knowledge of the plants and other natural productions of the country. In theſe purſuits he was much aſſiſted by correſponding with Dr. Fothergill, who procured and ſent him the neceſſary books, accompanied with hints, ſuggeſting the objects moſt deſerving his attention. In 1749 he quitted Minorca, and went to Ireland, and the year following he came to London, and publiſhed his "Treatiſe on the Diſeaſes of Minorca," 8vo. the reſult of his obſervations during his long reſidence in the iſland. The work is valuable, containing accounts of the air and ſoil, with deſcriptions of the medicinal plants. Then follow accounts of the diſeaſes moſt frequent in the country, with the methods he found moſt efficacious in combating them. He now went to Dublin, and commenced lecturer in anatomy, in which he acquired ſuch celebrity, that in 1754 he was appointed profeſſor in that ſcience by the univerſity. In 1774 he was made honorary member of the College of Phyſicians in Dublin. He was alſo one of the original members of the Academy for promoting Arts and Sciences in that city; and, about the ſame time, he had the honour of being nominated fellow of the Royal Medical Society at Paris. As Dr. Cleghorn had no family, he ſent for the widow of his brother, with nine children, whom he adopted, and treated as his own. He died December 1789. Lettſom's Memoirs of Medicine.

CLEGUEREE, in *Geography*, a town of France, in the department of Morbihan, and chief place of a canton in the diſtrict of Pontivy, two leagues N.W. of it. The place contains 2793, and the canton 14,964 inhabitants; the territory comprehends 187½ kiliometres and 9 communes.

CLEIDES, or Clides *inſulæ*, in *Ancient Geography*, ſmall iſlands of the Mediterranean, lying to the eaſt of the iſland of Cyprus, and very near it. Strabo reckons two, and Pliny four. The promontory near theſe iſlands had the ſame name, according to Herodotus.

CLEIDION, in *Antiquity*, the ſame with *clavicula*. See Claviculæ.

CLEIDOMASTOIDEUS, in *Anatomy*, a name given by Albinus to that part of the ſterno-cleido-maſtoideus, which ariſes from the clavicle, and is deſcribed by him as a diſtinct muſcle. See Sterno-cleido-mastoideus.

CLELBY River, in *Geography*, one of the ſtreams which fall into Milford Haven in South Wales, navigable up to Canniſter bridge near Narberth. See Canal.

CLELLES, a town of France, in the department of the Iſere, and chief place of a canton in the diſtrict of Grenoble; the place contains 681, and the canton 3811 inhabitants; the territory includes 162½ kiliometres and 9 communes.

CLEMA, in *Antiquity*, a ſpecies of vine, a twig of which was the enſign of a centurion's office.

CLEMATIS, in *Botany*, (from κλημα, *riticula*, *ſarmentum*, becauſe it climbs trees, by means of its pliant twigs, like thoſe of the vine), Linn. Gen. 696. Schreb. 950. Willd. 1083. Gært. 456. Juſſ. 232. Vent. 3. 55. Claſs and order, *polyandria polygynia*. Nat. ord. *Multiſiliquæ*, Linn. *Ranunculaceæ*, Juſſ. Vent.

Gen. Ch. *Cal.* none. *Cor.* Petals four, rarely five, ſix or eight, oblong, lax, pubeſcent. *Stam.* Filaments numerous, awl-ſhaped, ſhorter than the corolla; anthers adnate to the filaments. *Piſt.* Germs from four to twenty, roundiſh, compreſſed; ſtyles awl-ſhaped, longer than the ſtamens. *Peric.* none. *Seeds* numerous, roundiſh, compreſſed, tailed with the long permanent ſtyle in various forms.

Eſſ. Ch. Calyx none. Petals four, five or ſix. Seeds tailed.

Obſ. 1. Gærtner calls the external integument of the ſeed a capſule; but acknowledges at the ſame time, that, as there is no viſible umbilical cord, the ſeed may not improperly be ſtyled naked.

Obſ. 2. La Marck aſſerts that there is no real generic diſtinction between clematis and atragene; and that Linnæus abſurdly calls the ſame part of the fructification *corolla* in one, and *calyx* in the other. According to him, what Linnæus took for petals in atragene are only enlarged and often barren filaments of the exterior ſtamens; a circumſtance which occurs in ſeveral acknowledged ſpecies of clematis, and in ſome of nymphæa.

* *Stems climbing.*

1. C. *cirrhoſa*, Linn. Sp. Pl. 7. Mart. 1. Lam. 9. Willd. 1. (Clematitis peregrina, foliis pyri inciſis, Bauh. Pin. 300. Petiv. Gaz. tab. 126. fig. 1. Tourn. Inſt. 293. C. altera bætica, Cluſ. Hiſt. 1. p. 123. C. cretica foliis nunc ſingularibus nunc ternis, Tourn. Cor. 20.) Ever-green virgin's bower. "Cirrhoſe; leaves ſimple." Linn. "Leaves generally ſimple; ſtem cirrhoſe; peduncles lateral, calycled under the flower." Lam. *Stem* woody, reſembling that of the vine, ten or twelve feet high, ſending out branches from every joint, which render it a thick buſhy plant. *Branches* cylindrical, leafy, attaching themſelves to neighbouring objects by means of a kind of cirri, which are, in fact, only the permanent petioles of fallen leaves, none of them being found on the young ſhoots. *Leaves* on the ſame plant both ſimple and ternate; thoſe on the woody part of the ſtem,

and on the branches of two years growth, simple, petioled, egg-shaped, toothed, a little resembling those of the pear tree, but smaller; growing on the knots, often several together, in the axils of the cirri; those on the young shoots commonly ternate, opposite, petioled; leaflets egg-shaped, a little cut or crenulate, smooth, green, shining. *Flowers* white; peduncles scarcely an inch long, lateral, axillary, one-flowered; petals large, elliptical, pubescent on the outside; calycle, or rather involucre, one-leafed, concave, two-lobed, situated two or three lines below the corolla. *Seeds* with a plumose or silky tail. A native of Andalusia and the island of Candia, but is sufficiently hardy to bear the cold of our winters without injury. There are plants in Chelsea garden which have stood more than fifty years in the open air without protection from the severity of the weather. It is used as a covering for arbours and other trellis-work, which it completely covers with its thick foliage, and adorns with its large flowers. Gerard, by whom it was cultivated in 1596, calls it "Travellers' joy of Cardia;" Johnson, "Spanish traveller's joy;" and Parkinson, "Spanish wild climber." 2. C. *florida*, Willd. 2. Hort. Kew. 2. p. 258. Thunb. Jap. 240. Bot. Mag. 894. "Leaves twice compound; leaflets binate and ternate; petals egg-shaped." *Root* perennial. *Stem* striated, purple, entirely smooth. *Leaves* opposite, pinnæ sessile, egg-shaped, acute, entire, or very rarely cut, villous. *Flowers* yellowish, large, spreading, axillary, solitary, peduncled; peduncle villous, one-flowered, longer than the leaves; petals egg-shaped, acuminate: stamens linear-lanceolate, purplish, unequal, half the length of the corolla, Thunb. A native of Japan. 3. C. *viticella*, Linn. Sp. Pl. 1. Mart. 2. Lam. 12. Willd. 3. Bot. Mag. 565. (Clematitis cærulea vel purpurea repens, Bauh. Pin. 300. —— flore pleno, 301. Tourn. 294.). "Leaves compound, and twice compound; leaflets egg-shaped, quite entire." Linn. "Leaves compound, and twice compound; petals margined, dilated at the tip, spreading." Lam. *Root* perennial. *Stems* slender, weak, branched, leafy, with many joints. *Leaflets* from nine to fifteen, ovate-acute, smooth, entire, sometimes with one or two lobes; upper ones simple or ternate. *Flowers* blue, obsolete-purple, bright purple or red, peduncled; petals bordered on each side by a thin, whitish, pubescent membrane, which grows broader near the tip, and makes them appear wedge-shaped; stamens small; filaments short; styles quite smooth. A native of Spain and Italy in hedges. Four varieties are cultivated in the nurseries: single blue, single purple, single red, and double purple. The latter is esteemed the most ornamental, and continues the longest in flower, opening its flowers in June or July, and retaining them to the end of August. There is another variety, but not much esteemed, with white flowers, only three or four feet high, which Miller received from mount Baldo. 4. C. *viorna*, Linn. Sp. Pl. 2. Mart. 3. Lam. 13. Willd. 4. (Flammula scandens, flore violaceo clauso, Dill. Elth. tab. 118. fig. 144.) Leathery-flowered virgin's bower. "Leaves compound and twice compound; some of the leaflets trifid." Linn. "Leaves compound and twice compound; petals coriaceous, acute, half shut." Lam. *Root* perennial. *Stems* three or four feet high, cylindrical, striated. *Leaves* opposite, petioled; leaflets from nine to twelve, three on each pinna, generally entire, a few trifid, ovate-acute, green and smooth on the upper surface, veined and paler underneath. *Flowers* purple or bluish violet, axillary, solitary; peduncles long, with a pair of simple leaves in the middle; petals with a whitish, cottony border, smaller than that of the preceding species; anthers terminated with a tuft of hairs. *Seeds* with long plumose tails. A native of Virginia and Carolina. 5. C. *crispa*, Linn. Sp. Pl. 3. Mart. 4. Lam. 14. Willd. 5. Dill. Elth. tab. 73. fig. 84. Curled virgin's bower. "Leaves simple and ternate; leaflets entire or three-lobed." Linn. "Leaves compound, and twice compound; leaflets lanceolate; petals half-shut, somewhat curled at the sides; margin membranous, undulated, wrinkled." Lam. *Root* perennial. *Stems* weak, fastening themselves to the neighbouring plants by the twining petioles of their leaves. *Leaflets* from nine to fifteen, narrower than those of the preceding species. *Flowers* large, reddish, solitary; peduncles short; petals less thick than those of C. viorna, with many longitudinal furrows; anthers hairy at the summit. Tails of the seeds thick, awl-shaped, not plumose, but pubescent with short close-pressed hairs. A native of Carolina. Thunberg describes a Japanese plant under the same name, with a stem striated, zig-zag, smooth; leaves five-nerved, petioled, acute, smooth; and flowers in a compound, trichotomous panicle; but its mode of inflorescence must surely determine it to be a distinct species. 6. C. *calycina*, Mart. 16. Willd. 6. Hort. Kew. 2. 259. Vahl. Symb. 2. 75. Bot. Mag. 959. (C. balearica, Lam. 10.). Minorca virgin's bower. "Involucre calycine, approximating; leaves ternate, middle one three-parted." Hort. Kew. "Leaves compound, finely laciniated; flowers calycled, lateral; petals spotted within." Lam. *Root* perennial. *Stem* six feet high or more, branched, leafy. *Leaves* opposite, green, smooth, continuing nearly all the year; petioles tripartite, remaining after the leaves, and discharging the office of tendrils. *Flowers* white, large, solitary, axillary; peduncles two inches long; involucre one-leafed, bell-shaped, two-lobed, changing sometimes into a pair of leaves; petals elliptic-oblong, nerved, pubescent on the outside; sprinkled on the inside with small, red, longish spots; filaments a little enlarged at their base; anthers small; styles plumose and silvery. A native of Minorca, flowering in autumn, and often in winter when the season is mild. 7. C. *orientalis*, Linn. Sp. Pl. 4. Mart. 5. Lam. 5. Willd. 7. (Clematitis orientalis apii folio, Tourn. Cor. 20. Flammula, Dill. Elth. tab. 119. fig. 145.). "Leaves compound; leaflets cut, angular, lobed, wedge-shaped; petals villous on the inside." Linn. "Leaves compound; leaflets wedge-shaped, three-lobed, somewhat toothed, acuminate; petals villous on the inside." Willd. *Root* perennial. *Stems* from four to eight feet high, striated, leafy. *Leaves* glaucous. *Flowers* yellowish, with a tinge of russet on the outside; petals lanceolate, almost smooth on the outside, in short panicles on tripartite peduncles. Tails of the *seeds* plumose, silky. A native of the Levant. 8. C. *glauca*, Willd. 8. Willd. Arb. tab. 54. fig. 1*. "Leaves compound; leaflets egg-shaped, sometimes lobed, obtuse, mucronate; petals smooth within side, pubescent at the edge." Perfectly distinct from the preceding in its whole habit, as well as in the particulars expressed in the specific character. 9. C. *hexapetala*, Linn. Jun. Supp. 271. Forst. Prod. n. 230. "Leaves compound; leaflets egg-shaped, serrated; peduncles two-leaved; corolla spreading, with six petals." *Root* perennial. *Flowers* yellowish, dioicous; peduncles branching, trichotomous. A native of New Zealand. 10. C. *triflora*, Willd. 10. Vahl. Symb. 3. p. 74. (C. mauritiana, Lam. 6.) "Leaves ternate; leaflets egg-shaped, mucronate; peduncles three-flowered." Vahl. "Leaves ternate; leaflets somewhat heart-shaped, serrated; tail of the seeds very long, plumose." Lam. *Root* perennial. *Stems* slightly striated. *Flowers* whitish; peduncles lateral, opposite, axillary near the end of the short pendant branches; petals oblong, villous on both sides. *Seeds* purple, villous. A native of the islands of Bourbon and Madagascar, in woods. The natives of Madagascar make

a cataa cataplasm of the leaves, and employ it as a cure for the tooth-ache. The cataplasm is carefully wrapped up in eight or ten folds of linen, and applied externally to the cheek of the patient. If suffered to touch the skin, it will produce a blister. 11. C. *virginiana*, Linn. Sp. Pl. 6. Mart. 7. Lam. 7. Willd. 11. Pluk. Mant. tab. 389. fig. 4. (C. Floridensis flore albo odoratissimo; Albin. Anat. tab. 7. C. aquatica trifoliata; Gron. Virg. n. 270.) "Leaves ternate; leaflets heart-shaped, somewhat lobed and angular; flowers dioicous." *Root* perennial. *Stems* numerous, six feet high, or more. *Leaves* smooth, dark green on the upper surface, almost three-nerved underneath; veins branched, reticulated. *Flowers* white, in short panicles, resembling umbels; peduncles once or twice ternate; petals villous on the outside, naked and veined within. The female flower has stamens, but the anther is destitute of pollen. 12. C. *japonica*, Mart. 9. Lam. 16. Willd. 12. Thunb. Jap. 240. "Leaves ternate; leaflets elliptic-ovate, serrated; flowers cylindrical." *Root* perennial. *Stem* filiform, striated, purple, villous. *Leaves* petioled, ternate, growing several from each joint; petiole three inches long, capillary, loose; leaflets an inch long, on short petioles, acuminate, uniformly serrated from the middle to the tip, nerved, villous, the terminating one largest. *Flowers* purple, solitary, lateral, peduncled; peduncles the length of the leaflets. A native of Japan, flowering in August and September. 13. C. *trifoliata*, Willd. 13. Thunb. in "Linnæan Transactions," vol. ii. p. 337. (Scandens, Flor. Jap. n. 43.) "Leaves opposite, ternate, smooth; leaflets egg-shaped, repand-toothed." A native of Japan. 14. C. *dioica*, Linn. Sp. 5. Mart. 10. Lam. 8. Willd. 14. Sloan. Jam. 84. Hist. tab. 128. fig. 1. "Leaves ternate, quite entire; flowers dioicous." *Root* perennial. *Stems* slender, tough, ten or twelve feet high. *Leaves* coming out on each side of the stem; leaflets large, egg-shaped, with three or five longitudinal nerves. *Flowers* white; peduncles on the joints close to the petioles, one on each side, long, naked, horizontal, extending beyond the leaves, before they divide and branch; branching into three or four pairs of subordinate peduncles, these dividing again into three smaller, each of which supports a single flower. The lowest pair of primary peduncles extends four or five inches, the others gradually diminishing to the top, and forming a pyramidal thyrse of flowers; petals narrow, reflexed; stamens erect. Miller. A native of South America. La Marck doubts whether it be specifically distinct from C. virginiana, but from Miller's description, the inflorescence is clearly different. Loureiro found a plant in Cochin China, which he supposed to be the same as the C. dioica of Linnæus. It has about eighty seeds disposed in a head, which are obtusely three-cornered, and compressed, with a very long tail, fringed with many white hairs. But its identity may justly be doubted. Its inflorescence seems to approach nearer that of C. virginiana. 15. C. *americana*, Mart. 17. "Leaves ternate; leaflets cordate-acuminate, quite entire; flowers in corymbs." *Root* perennial. *Stems* strong, twenty feet high, or more, fastening themselves by their claspers to the neighbouring trees. *Flowers* white; peduncles axillary, long, naked, branching. *Seeds* finely feathered. Sent to Miller from Campeachy, by Dr. Houston. 16. C. *indivisa*, Willd. 15. (C. integrifolia, Forst. Prod. n. 231.) "Leaves ternate; leaflets egg-shaped, quite entire, mucronate; peduncles axillary, panicled, two-leaved." A native of New Zealand. 17. C. *paniculata*, Willd. 16. Thunb. in "Linnæan Transactions," 2. 337. (C. crispa, Thunb. Jap. 239.) "Leaves quinate-pinnated; leaflets heart-shaped, egg-shaped, entire." *Root* perennial. *Stem* zig-zag, striated, smooth. *Branches* alternate. *Leaves* petioled; leaflets petioled, acute, undivided, smooth; lower ones the largest; petioles zig-zag. *Flowers* white, axillary; peduncles thrice-ternate-panicled, filiform. A native of Japan. 18. C. *chinensis*, Mart. 18. Willd 18. Retz. Obs. 2. tab. 2. "Leaves quinate-pinnated; leaflets lanceolate." *Root* perennial. *Stems* tetragonous, weak, so as to want support, scarcely climbing. *Leaflets* petioled, the pairs remote from each other. *Flowers* pale purple, small, opposite, axillary; peduncles three, or five-flowered; lateral pedicels with a pair of small bractes, far removed from the flower; end one naked; petals linear-lanceolate, inner edge marked with a tomentous line. Tail of the pistils scarcely shorter than the anthers. Retz. A native of China. 19. C. *sinensis*, Lour. Cochin. 345. 3. "Leaves quinate; leaflets ovate-lanceolate, nearly sessile." *Stems* round, very long, branched, climbing. *Flowers* red purple; peduncles axillary, many-flowered; corolla spreading. *Seeds* three to five. Common in China. Professor Martyn justly remarks, that this plant seems specifically distinct from the preceding. 20. C. *minor*, Mart. 21. Lour. Cochinch. 345. "Leaves quinate; leaflets conical, three-nerved; peduncles very long." *Stem* somewhat shrubby, not very long, cylindrical, slender, climbing, branched. *Leaflets* small, bluntish at the end, quite entire, smooth. *Flowers* white, axillary, several together; petals oblong, striated; stamens about forty, unequal; styles four, hairy, a little longer than the corolla. A native of the suburbs of Canton in China. 21. C. *vitalba*, Linn. Sp. Pl. 8. Mart. 11. Lam. 1. Willd. 17. Gært. tab. 74. fig. 3. Curt. Lond. Fasc. 4. tab. 37. Jacq. Aust. tab. 308. Eng. Bot. tab. 612. (C. sylvestris latifolia, Bauh. Pin. 300. Viorna, Ger. em. 886.) Common virgin's bower, Traveller's joy, or Old man's beard. "Leaves pinnated; leaflets heart-shaped; petioles twining." β. C. Canadensis. "Leaves broader; leaflets growing by threes." *Root* perennial. *Stems* branched, leafy, furrowed, twining round other plants by means of the twisted petioles of the fallen leaves. *Leaves* opposite, unequally pinnated; leaflets growing by fives, petioled, egg-shaped, acute, either entire, or irregularly cut, rather smooth. *Flowers* white, sweet-scented; panicles axillary, dichotomous, pubescent, with small bracteal leaves; petals coriaceous, villous on both sides. *Seeds* with long plumose tails, which adorn the hedges in autumn, and during great part of the winter. Dr. Smith. *Seeds* about twenty, membranous, slender, reddish; on a small villous, somewhat globular receptacle. Gært. The recent leaves, when rubbed on the skin, produce blisters, and are said to be used by beggars, to give the appearance of foul ulcers on different parts of the body or limbs, for the sake of exciting compassion. But these ulcers, though large, are never deep, and are very little troublesome, being easily removed at pleasure, by an application of beet-leaves, to preserve them from the influence of the atmospheric air. A native of England, and the south of Europe, chiefly on a calcareous soil. Though not enumerated by Messrs. Dawson, Turner, and Dilwyn, among the rare plants in their "Botanist's Guide;" it is certainly very local. We have never observed it north of Alconbury hill, on the great north road; nor of Northampton, on the middle one. Where it terminates on the Chester road, we cannot exactly ascertain, but suppose it must disappear nearly in a continuation of the same line, not having met with it in Warwickshire, or any of the counties farther north, on that side of England. In the "Botanist's Guide through the Counties of Northumberland and Durham," it is mentioned as growing only on the Ballast hills of St. Anthony's, and Willington Quay, in Northumberland, where no one will suppose it indigenous. It is, we believe,

believe, a total ſtranger to the great limeſtone tracts in Yorkſhire, and the biſhoprick of Durham; nor was it found by Lightfoot in Scotland. The pith of the ſtems is ſo porous, that if one end of a piece, cut off between the knots, be ſet on fire, ſmoke may be copiouſly drawn into the mouth from the other. This, we well remember, was a favourite amuſement of our boyiſh days, in the neighbourhood of Northampton, when we knew the plant by no other name than that of tobacco-pipe tree. Variety β is a native of Canada. 22. C. *flammula*, Linn. Sp. Pl. 9. Mart. 12. Lam. 4. Willd. 19. (Clematitis ſive flammula repens, Bauh. Pin. 300. Tourn. Inſt. 293. Rai. Hiſt. 621). "Lower leaves pinnated, twining, laciniate; upper ones ſimple, quite entire, lanceolate." Linn. "Leaves twice pinnated; pinnæ generally three-leaved; leaflets ſmall, egg-ſhaped, rarely lobed." Lam. *Root* perennial. *Stems* numerous, about two feet long, rather creeping than climbing, ſlender, ſtriated, leafy. *Flowers* white, ſmall, ſweet-ſcented, in a kind of terminal panicle; peduncles once or oftener divided in a ternate manner; with ſmall, oppoſite, ciliated bractes under their diviſions. *Seeds* few, with a plumoſe tail.

* * *Stems erect.*

23. C. *maritima*, Linn. Sp. 10. Mart. 13. Lam. 3. Willd. 20. (C. maritima repens; Bauh. Pin. 300. Prodr. 135. Tourn. 294. Allion: Nic. 122.) "Leaves pinnated, linear; ſtems ſimple, hexagonal." Linn. *Root* perennial. *Stems* a foot and half high, ſlender, ſtriated, decumbent near the bottom, afterwards aſcending, or quite erect. *Leaves* oppoſite; leaflets linear, narrow, clothed with ſhort hairs, ſomewhat rigid, nearly ſeſſile, generally undivided, ſometimes bifid or trifid. Magnol and Ray make it a variety of C. flammula; but Linnæus thinks it more nearly allied to C. recta, and perhaps only changed by difference of ſituation. A native of the ſea coaſt in the ſouth of France and the neighbourhood of Venice. 24. C. *anguſtifolia*. Willd. 21. Jacq. Ic. Rar. 1. Tab. 104. (C. hexapetala, Pall. Itin. 3. App. n. 96. tab. Q. fig. 2. Atragene; Gm. Sib. iv. p. 194.) "Leaves pinnated; leaflets lanceolate, obtuſe; lower ones tripartite; ſtems ſimple, ſtriated, erect; corollas polypetalous." Willd. *Root* perennial. *Flowers* white; petals ſix or eight. A native of Siberia and Auſtria. 25. C. *recta*, Linn. Sp. Pl. 11. Mart. 14. Lam. 2. Willd. 22. Jacq. Auſt. tab. 291. Hall. Helv. n. 1144. Wood. 21. Med. Bot. tab. 62. (Flammula recta; Bauh. Pin. 300. Clematitis ſive flammula ſurrecta alba, Tourn. Inſt. 294.) "Leaves pinnated; leaflets ovate-lanceolate, quite entire; ſtem erect; flower pentapetalous and tetrapetalous." Linn. *Stems* three feet high, leafy, ſtriated, herbaceous, greeniſh or reddiſh. *Leaves* large, oppoſite; leaflets from five to nine, pubeſcent underneath, petioled. *Flowers* white; in upright, ſtiff, terminal umbels; peduncles ſeveral times ternate; petals oblong, obtuſe, ſomewhat villous, a little longer than the ſtamens. *Seeds* few, dark brown, ſmooth, orbicular, much compreſſed; tails long, yellowiſh, plumoſe. A native of uncultivated hills in the ſouth of France, Spain, Switzerland, Auſtria, Hungary, and Tartary. This, like ſome of the other ſpecies of this genus, is extremely acrid, on which account it was called flammula by the old botaniſts, and has obtained a place in the Edinburgh diſpenſatory. It had long been mentioned as an external remedy, but was firſt recommended by baron Stoerck of Vienna in 1769, as an uſeful internal medicine in inveterate ſyphilitic diſeaſes, and ulcers proceeding from other cauſes, cancers, &c. He employed the leaves and flowers, as well as an extract made from the former; but he chiefly uſed an infuſion of two or three drams of the leaves in a pint of boiling water, of which he gave four ounces three times a day, and applied the powdered leaves as an eſcharotic to the ulcers. Unhappily the phyſicians of this country have not found it equally efficacious. See Woodville's Medical Botany. 26. C. *ochroleuca*, Mart. 19. Willd. 23. Hort. Kew. 2. p. 260. Pluk. Mant. tab. 379. fig. 5. "Leaves ſimple, egg-ſhaped, pubeſcent, quite entire; flowers erect." A low unbranched ſhrub. *Stem* pubeſcent. *Leaves* oppoſite, ſeſſile, ſtrongly nerved. *Flower* terminating, ſingle, pale yellow. A native of North America. 27. C. *integrifolia*, Linn. Sp. Pl. 12. Mart. 15. Lam. 15. Willd. 24. Jacq. Auſt. tab. 363. Bot. Mag. 65. (C. nutans, Crantz. Auſt. p. 124. C. inclinata, Scop. Carn. p. 668. Clematitis cærulea erecta. Bauh. Pin. 300. Tourn. Inſt. 294.) "Leaves ſimple, ſeſſile, ovate-lanceolate, flowers drooping." Linn. *Root* perennial. *Stems* a foot and half or two feet high, annual, erect, ſimple, ſometimes with two branches near the top, angular, ſtriated, almoſt ſmooth, leafy. *Leaves* oppoſite, quite entire, pubeſcent at their edges. *Flowers* blue, large, ſolitary, terminal, ſcentleſs; petals large, lanceolate, acute, waved, thick, ſpreading very much. (half open, Lam.); filaments very pale yellow; villous, twice the length of the petals. *Seeds* roundiſh, compreſſed, ſomewhat villous, with a long plumoſe tail. A native of Germany, Auſtria, Carniola, Hungary, and Tartary, flowering from June to Auguſt. Cultivated by Gerard in 1596; and now not uncommon in the nurſeries about London. Forſter, Flor. Auſt. n. 231. has given the ſame name to a very different plant from New Zealand with ternate leaves; the leaflets ovate, entire, mucronate; the peduncles axillary, panicled, two-leaved.

CLEMATIS, in *Gardening*, comprehends plants of the flowery, perennial, and fhrubby kinds of hardy growth; of which the fpecies chiefly cultivated are; the purple virgin's bower, (C. *viticella*); the leathery-flowered virgin's bower, (C. *viorna*); the oriental virgin's bower, (C. *orientalis*); the virginian virgin's bower, (C. *virginiana*); the curled-leaved virgin's bower, (C. *crifpa*); the evergreen virgin's bower, (C. *cirrhofa*); the fweet-fcented virgin's bower, (C. *flammula*); the upright virgin's bower, (C. *erecta*); the entire-leaved virgin's bower, (C. *integrifolia*). They have all climbing flender ftems and branches, except the two laft, in which they are upright with numerous flowers. Of the firft fort there are varieties with fingle blue, fingle purple, fingle red, and double purple flowers, in cultivation.

And of the eighth fort there is a variety with only two or three pairs of leaflets, which are narrower and ftand farther afunder, having fhorter ftalks and larger flowers.

Method of Culture.—The firft or purple virgin's bower, and the different varieties, as well as the fix following forts, are capable of being readily increafed by layers, and fome of them even by cuttings of the young fhoots, planted out in the fpring or fummer months, but the firft is the moft ufual method.

In this the layers fhould be made from the fhoots of the preceding or the fame year, and be laid down in the fummer before they become woody, as in this way they fucceed with greater certainty. The branches fhould have their tops left a few inches out of the earth, a little water being given at the time. When they are become well rooted, as in the following autumn or fpring, they may be taken off and planted out where they are to remain, or in the nurfery, to remain till they have attained fome growth.

The fhoots of the evergreen fort may however be laid down at any feafon, but the above is the beft. It is alfo capable of being raifed from cuttings of the young fhoots planted out in either the fpring or fummer months in pots of good earth, plunging them in a very moderate hot-bed. The fuckers from the roots may likewife be taken off and be planted out in the fame manner as the layers, when they will often produce good plants, and in a fhort time. The two laft forts are capable of being readily increafed by parting the roots, and planting them out either in the autumn or the early fpring months, in a bed of good mould. In this way every part which has fibres preferved at the bottom, and a bud in the upper part, will readily take root and become a plant. And thefe forts, as well as fome of the others, may alfo be propagated by fowing the feeds either where the plants are to remain, or in a fpot of good mould in the early autumn or fpring feafon, in the latter cafe removing the plants into their proper fituations, when of fufficient growth. In this mode the plants are, however, longer in arriving at the flowering ftate. The roots may be divided every two or three years, according to the number of divifions that are to be made. Where the foil is dry the plants fhould be new planted in the autumn; but in the contrary circumftances, in the fpring, in order to make them flower ftrong and in a perfect manner. All thefe plants are of a hardy growth; and capable of fucceeding in almoft any fort of foil. The climbing forts require proper fupport, to prevent their trailing upon the ground, and are well adapted for ornamenting naked walls, arbours or other fimilar places, as well as for running upon trees or fhrubs in particular fituations. And the two laft forts are well fuited for ornament in the clumps and borders of pleafure-grounds, to be fet out fingly or in affemblage with other plants of fimilar growths.

CLEMATITIS, in *Botany*, Bauh. Pin. Tourn. See CLEMATIS.

CLEMATITIS *novum genus*, Pluk. See EUPATORIUM *fcandens*. The older botanifts were accuftomed to call almoft every climber either clematis or clematitis.

CLEMENCY, in *Antiquity*, a deified perfonage, to whom an altar was erected at Athens, by the kindred of Hercules, and to whom a temple was dedicated by order of the Roman fenate, after the death of Julius Cæfar, on fome of whofe denarii this goddefs appears. She is defcribed by the poets as the guardian of the world, and exhibited, holding a branch of laurel or olive, and alfo a fpear, fhewing that gentlenefs and pity ought principally to diftinguifh victorious warriors. The Greeks and Romans gave the name of Afylum to the temples that were erected to this goddefs. According to Mr. Spence, "the diftinguifhing character of Clemency, both in her ftatues and in the poets is, the mildnefs of her countenance; fhe has an olive branch in her hand as a mark of her peaceful and gentle temper." The term "clemency" in common language, denotes a remiffion of feverity towards offenders, and particularly on the part of princes or perfons invefted with high authority. In praife of clemency joined with power, it is obferved, that the exercife of it is not only the privilege, the honour, and the duty of a prince, but that it alfo contributes to his perfonal fecurity and that of his dominions more effectually than all his garrifons, forts, and guards; that the prince is truly royal who mafters himfelf, looks upon all injuries as below him, and governs by equity and reafon, and not by paffion and caprice. Many remarkable inftances occur both in the Grecian and Roman hiftory, in which clemency was exercifed with great honour and correfponding advantage.

The council of Thirty, eftablifhed at Athens by Lyfander, committed the moft execrable cruelties; but they were overthrown by Thrafybulus, who, after the recall of the exiles propofed the celebrated amnefty, by which the citizens engaged upon oath that all paft tranfactions fhould be buried in oblivion. The government was re-eftablifhed upon its ancient foundation, the laws reftored to their priftine vigour, and magiftrates elected with the ufual forms. This, fays Rollin, (Anc. Hift. vol. iii. p. 309.) is one of the fineft events in ancient hiftory, worthy of the Athenian lenity and benevolence, and has ferved as a model to fucceffive ages in good government. Never had tyranny been more cruel and bloody than that from which the Athenians had been refcued. Every houfe was in mourning; every family bewailed the lofs of fome relation. It had been a feries of public robbery and rapine, in which licence and impunity had authorifed all manner of crimes. The people feemed to have a right to demand the blood of all accomplices in fuch notorious malverfations, and even the intereft of the ftate to authorife fuch a claim, that by exemplary feverities fuch enormous crimes might be prevented for the future. But Thrafybulus rifing above thofe fentiments, from the fuperiority of his more extenfive genius, and the views of a more difcerning and profound policy, forefaw, that by giving way to the punifhment of the guilty eternal feeds of discord and enmity would remain, to weaken the republic by domestic divisions, which it was necessary to unite against the common enemy, and occasion the loss to the state of a great number of citizens, who might render it important services from the view itself of making amends for past misbehaviour. Such a conduct, continues Rollin, after great troubles in a state, has always seemed, with the ablest politicians, the most certain and ready means to restore the public peace and tranquillity. Another instance occurs in the history of Pausanias, one of the kings of Sparta, when at the head of the Grecian army. After the victory of Platæa, as Herodotus relates the fact, (Lib. v.) one of the principal citizens of Ægina advised him to revenge upon the body of Mardonius the death of so many brave Spartans as were slain at Thermopylæ, and the unworthy treatment which his uncle Leonidas had met with from Xerxes and Mardonius, who fixed his body to a gibbet. "Would you advise me then, says he, to imitate the barbarians in the the thing we hate? If the esteem of the people of Ægina is to be bought at so dear a rate, I shall be content with pleasing the Lacedæmonians, who set a value upon virtue and merit. As to Leonidas and his companions, they are without doubt sufficiently revenged by the blood of so many thousand Persians as have been slain in the battle." In this battle out of 300,000 men commanded by Mardonius, scarcely 40,000 escaped.

When two patricians, adverting to the history of Rome, conspired against Titus the Roman emperor, (Suet. c. 9.) they were discovered, convicted, and sentenced to death by the senate. But the clemency of Titus dictated a very different conduct. Having sent for them, he privately admonished them, that in vain they aspired to the empire, which was given by destiny; exhorting them to be satisfied with the rank in which Providence had placed them, and offering them any thing else which it was in his power to bestow. At the same time he dispatched a messenger to the mother of one of them, who was then at a great distance, and deeply concerned about the fate of her son, to assure her, that her son was not only alive, but forgiven. Another instance is recorded by Zosimus (ii. 674). When Licinius had raised an army of 130,000 men, he endeavoured to wrest the government out of the hands of his brother-in-law, Constantine, the emperor. But his army having been defeated, he fled to Nicomedia, whither he was pursued by Constantine, who immediately invested the place. On the second day of the siege, the emperor's sister intreated him with tears to forgive her husband, and grant him at least his life. Constantine was prevailed upon to comply with her request; and the next day, Licinius, finding no way of escape, presented himself before the conqueror, and throwing himself at his feet, yielded to him the purple and the other ensigns of sovereignty. Constantine received him in a friendly manner, entertained him at his table, and afterwards sent him to Thessalonica, assuring him, that he should live unmolested as long as he raised no new disturbances. Another instance occurs in the conduct of Cicero, when Rome was divided into two factions upon the occasion of the death of Cæsar, who had been killed by the conspirators; recollecting the celebrated amnesty of Thrasybulus above-mentioned, he proposed, after the example of the Athenians, to bury all that had passed in eternal oblivion.

In a manner somewhat similar, cardinal Mazarine observed to don Lewis De Haro, prime minister of Spain, that this gentle and humane conduct in France had prevented the troubles and revolts of that kingdom from having any fatal consequences, and "that the king had not lost a foot of land by them to that day;" whereas "the inflexible severity of the Spaniards was the occasion that the subjects of that monarchy, whenever they threw off the mask, never returned to their obedience but by force of arms; which sufficiently appears, (says he) in the example of the Hollanders, who are in the peaceable possession of many provinces, that not an age ago were the patrimony of the king of Spain."

Montesquieu observes (Spirit of Laws, vol. i. p. 134.) that clemency is the peculiar characteristic of monarchs. In monarchies great men are governed by honour, which frequently requires what the law forbids, and they are so much punished by disgrace, by the loss (though often imaginary) of their fortune, credit, acquaintances, and pleasures, that rigour in respect to them is needless. It can lead only to divest the subjects of the affection they have for the person of their prince, and of the respect they ought to have for public posts and employments. So many are the advantages which monarchs gain by clemency, such love, such glory attend it, that it is generally a point of happiness with them to have an opportunity of exercising it.

However, when there is danger in the exercise of clemency, the danger is visible: it is an easy matter to distinguish it from that imbecility which exposes the princes to contempt, and to the very incapacity of punishing. The emperor Maurice formed a resolution never to spill the blood of his subjects. Anastasius punished no crimes at all. Isaac Angelus made an oath that no one should be put to death during his reign. These Greek emperors had forgotten that it was not for nothing that they were entrusted with the sword.

CLEMENS NON PAPA, in *Biography*, an excellent Netherlandish musical composer, principal maestro di cappella to the emperor Charles V. Ludovico Guicciardine tells us, that this musician was dead when he wrote his "Description of the Low Countries," 1556. Seven books of his motets in four parts ("Cantionum Sacrarum") were published after his decease, at Louvain, 1567, as was his "Missa Defunctorum," 1580. We have found no better music of the kind, than that of this composer; his style is clear, his harmony pure, and every subject of fugue or imitation simple and natural. In each of the great number of his works that we have scored, there is always some excellence; the last, however, that is seen, always appears the best. The several parts, in his French songs, sing better, and the composition is, in general, more pleasing, and like the best productions of a much better period, than any of the songs in the collections to which he was a contributor, that were published at Louvain about the middle of the sixteeth century, under the title of "Livres des Chansons a 4 Parties."

CLEMENS *Romanus*, *St.* CLEMÉNT, one of the apostolical fathers, and first bishop of Rome of that name, was a native of that city, as some have said; on mount Coelius, his father's name being Faustinus and his mother's Mattidia; but these particulars are uncertain. Some have asserted, that he was a Jew, or of Jewish extraction, alleging a passage in his epistle to the Corinthians, in which he calls Jacob our father; but such an expression, it has been said, is not unusual even among those who had been converted from Paganism to Christianity. Nothing is more natural than for Christians to speak as if they were Abraham's children; as if the law, and the prophets, and the patriarchs, belonged to them as well as to the Jews. (See Jortin's Remarks on Eccl. Hist. vol. i. p. 336, &c.). It is generally allowed, that he had been acquainted with apostles and apostolical men; and that he was the Clement, to whom St. Paul bears testimony (Phil. iv. 3.), and whom he mentions among others of his "fellow-labourers, whose names are in the book of life." Some, indeed, such are Mr. Wolff of Hamburgh, and Dr. Wall, have thought, that the Clement mentioned in this passage was a different person, and that he was a Philippian and not a Roman. To the arguments alleged by these writers, Dr. Lardner replies, that Clement, bishop of Rome, was well acquainted with some of our Lord's apostles, whether he be the person mentioned by St. Paul or not. This learned writer, whose judgment in every case of this kind challenges great deference, says, that he sees no proof that Clement mentioned by the apostle was a Philippian; and if Paul's calling Clement his helper or "fellow-labourer," in his epistle to the Philippians, is a proof that Clement had laboured with him at Philippi, his salutation of Aquila and Priscilla, in the epistle to the Romans (xvi. 3.), would prove that they had been the apostle's "helpers" at Rome, before he had been there. He adds, Dr. Wall's argument from the age of Clement has no weight at all; because there is no great distance between the supposed times of his and St. John's death; and yet St. John had been an apostle of Christ some while before Paul was converted. Clement therefore, bishop of Rome, without any inconsistency, may be supposed to have been a companion and fellow-labourer of Paul at several places, and yet live to about the end of the first century. Some difference of opinion has prevailed concerning the time when Clement obtained the bishopric of Rome. Bishop Pearson supposes, that Clement was bishop of Rome from the year of our Lord 69 or 70 to the year 83, the second of Domitian. Pagi is of opinion, that Clement succeeded Linus in 61, and occupied the see of Rome till 77, when he abdicated, and died long after a martyr in the year 100. Those learned men, who place the bishopric of Clement so early, or who suppose that he might have written his epistle to the Corinthians before he was bishop, (as Dodwell,) usually place it before the destruction of Jerusalem. Others suppose, that this epistle was written shortly after the end of the persecution under Nero, between the 64th and 70th year of Christ. Le Clerc places it in the year 69, and Dodwell in 64. Du Pin, Tillemont, and others think, that he was not bishop till the year 91 or 93. This was the opinion of Dr. Cave, when he wrote his Apostolici (*vid.* Life of St. Clement, § 4.) but he altered it afterwards. This, says Dr. Lardner, is the more common opinion, and is agreeable to the sentiments of Irenæus, Eusebius, and others, the most ancient Christian writers. Irenæus makes Clement the third in succession after the apostles. Eusebius also says, that in the 2d year of Titus, A. D. 79, Linus, bishop of the church of Rome, when he had governed it 12 years, delivered it to Anencletus; and in the 12th year of the reign of Domitian, A.D. 92, Anencletus, having been bishop of the church of Rome 12 years, was succeeded by Clement, whom the apostle mentions in his epistle to the Philippians. In another place Eusebius says, that in the beginning of Trajan's reign Clement still governed the church of Rome, who was the third in that succession, after Paul and Peter; for Linus was the first, and after him Anencletus; and he afterwards says, that Clement died in the 3d year of Trajan, (that is, A.D. 100); having been bishop 9 years. St. Jerom agrees with Eusebius; and he observes, that it was indeed the more common opinion of the Latins, that Clement was next after Peter, but he does not follow them. Tertullian, the most ancient Latin father remaining, though not so ancient as Irenæus, says, that Clement was ordained by Peter. But in this particular Tertullian might be mistaken; and the testimony of Irenæus, confirmed by Eusebius, is much more valuable than his. Dr. Lardner has suggested several methods of reconciling Tertullian with others. According to the most credible testimonies, Clement's bishopric of Rome must have commenced in the year 91 or 92. Some have supposed that our Clement was of the family of the Cæsars and that he suffered matyrdom. But both these suppositions seem to be originally owing to his having been confounded with "Flavius Clemens," the consul; who was a near relation of Domitian, and was put to death by him on account of his attachment to Christianity. That Clement was no martyr is fairly concluded from the silence of Irenæus, Tertullian, Eusebius, and others; who could not have omitted this circumstance, if there had been any ground for it.

The "Epistle" of Clement, still extant, appears to have been written in the name of the whole church of Rome to the church of Corinth, and therefore it is called at one time the epistle of Clement, and at another the epistle of the Romans, to the Corinthians.

The main design of it is to compose some dissensions, which subsisted in the church of Corinth about their spiritual guides and governors; which dissensions had been excited by a few turbulent and selfish persons. Clement recommends not only concord and harmony, but love in general, humility, and all the virtues of a good life, and several of the great articles and principles of religion. The style of it is clear and simple. It is called by the ancients an excellent and useful, or great and admirable epistle; and though Photius, upon the whole, commends it, yet he says that it contains several things liable to censure, or, in modern language, that it is a Socinian epistle. It should be recollected, however, that Photius is apt to censure the writers, who did not come up to the orthodoxy of his time. Nevertheless, the epistle deserves the commendations that have been bestowed upon it. It is not indeed entire, some pages being deficient in the MS. of it; and as we have only one MS. of it remaining, it cannot be altogether so correct, as if we had a number of copies to compare together.

As to the precise time when it was written, there has been some difference of opinion. It appears from expressions that occur in it, to have been written after some persecution, or at the conclusion of it; either the persecution of Nero about 64, or that of Domitian in 94, or 95. Several passages seem to intimate, that it was written after the latter, and not so soon as that of Nero. Irenæus says, that in the time of Clement, when many were alive, who had been taught by the apostles and when there was no small dissension among the brethren of Corinth, the church at Rome sent a most excellent letter to the Corinthians, persuading them to peace among themselves, &c. Eusebius also bears testimony to the excellence of this epistle, and to the dissension at Corinth which occasioned it; and he adds, that this epistle has been formerly, and is still publicly read in many churches. St. Jerom also says, that Clement wrote a very useful epistle in the name of the church of Rome to the church of Corinth, which in some places is read publicly. Upon the whole we may conclude, with Dr. Lardner, that this epistle was written at the latter end of the reign of Domitian, in the year 95, or rather 96. In this epistle there is but one book of the New Testament expressly named, which is the first epistle of St. Paul to the Corinthians, and which, it is said, was written by the apostle Paul. It contains frequent references and allusions to the Scriptures both of the Old and New Testament. Words of our blessed Lord, found in the gospels of Matthew, Mark, and Luke, are recommended with a high degree of respect, though without the names of the Evangelists. There are also supposed allusions to the Acts of the Apostles, the epistle of Paul to the Romans, both the epistles to the Corinthians, the epistles to the Galatians, Ephesians, Philippians, Colossians, the first to the Thessalonians, first and second to Timothy, the epistle to Titus, the epistle to the Hebrews, the epistle of James, and

and the first and second of Peter; but all without any name, or so much as a mark of citation. Mill allows, that it appears from this epistle, that Clement had in his hands not only our first three gospels, but also the Acts of the Apostles, and the epistle to the Romans, both the epistles to the Corinthians, and the epistle to the Hebrews: and the testimony thus given to the antiquity, genuineness, or authority, of the books of the New Testament, is to be esteemed not only the testimony of Clement, but likewise of the church of Rome in his time. Moreover, it ought to be allowed, that the Corinthians likewise, to whom this epistle was sent, were acquainted with, and highly respected, the books quoted, or alluded to. In this epistle there are not any quotations or references to any of the apocryphal gospels, as they are called. "Nor do I remember," says Dr. Lardner, "that any of the passages of the gospel according to the Hebrews, or that according to the Egyptians, which have been collected by learned men from the writings of the ancient Christians, are taken out of this epistle."

The epistle of which we have given the above account, is the only piece of Clement, which can be relied on as genuine. The second epistle, which some have been inclined to own as such, is expressly rejected by Photius; and Grabe has observed, that Dionysius, bishop of Corinth, in the second century, mentions only one epistle of Clement; that Clement of Alexandria and Origen, who have quoted the first, never take any notice of the second; nor yet Irenæus, who has particularly mentioned the first, and could not well have omitted to mention the other also, if he had known any thing of it. From all these circumstances Grabe concludes with great probability, that this piece was not written before the middle of the third century. As to the Constitutions, and Recognitions, ascribed to Clement; see these articles. Cave's Hist. Lit. t. i. p. 28. Jones's Canon, vol. i. Lardner's Works, vol. ii.

Clemens, Titus Flavius, Clemens Alexandrinus, or St. Clement *of Alexandria*, was born and educated, as some say, at Athens, or, according to others, at Alexandria, where he resided a considerable time, after his return from his travels through Greece, Calabria, Italy, the East, Palestine, and Egypt. Eusebius intimates that he was originally a heathen. He flourished in the latter part of the second, and the beginning of the third century, in the reign of Severus and his son Antoninus Caracalla; that is, between the years 192 and 217. Du Pin supposes, that he lived to the time of Heliogabalus, and that he did not die before the year 220; but it is the more general opinion, that he died sooner. Several of the ancients give him the title of Presbyter; and he was likewise president of the catechetical school of Alexandria, having succeeded Pantænus in this office, when he went to Ethiopia, about the year 190. Sidetes, indeed, is of a different opinion, and says that Pantænus was the successor of Clement, and that Clement was the successor and disciple of Athenagoras. Dodwell has adopted this opinion, though it is contradicted by the more credible testimonies of Eusebius, Jerom, and Photius. It is very probable, however, that upon the publication of the edicts of Severus against the Christians, in the 10th year of his reign, A.D. 202, Clement was obliged to resign this office and to retire from Alexandria. The place and time of his death are not ascertained; but he probably died at Alexandria, whither he returned from his peregrinations to Jerusalem, Antioch, &c. in the reign of Antoninus Caracalla. Among the eminent men who proceeded from the school of Clement, we may mention Origen, Alexander, bishop of Jerusalem, and Hippolytus. Clement wrote a great number of books, of which Eusebius and Jerom have given catalogues, and they are also enumerated by Fabricius and Cave. The works which now remain, are "Protrepticum," or an Exhortation to the Gentiles; "Pædagogus," or the Instructor, in three books; the "Stromata," or Various Discourses, in eight books; and a small treatise entitled, "Who is the rich Man that may be saved." The Stromata were written after the death of Commodus, in the reign of Severus, as Eusebius has observed from a passage in the work itself. Dodwell was of opinion, that all the works of Clement, which are remaining, were written between the beginning of the year 193 and the year 195. Beside these, Eusebius frequently mentions another book of Clement, called "Hypotuposes," or Institutions, which is lost. But we have in Greek two small pieces, one called "an Epitome of the Writings of Theodotus and the Oriental Doctrine;" the other "Extracts from the Prophets;" both which are generally supposed to be collected out of the lost book of Institutions, or to be fragments of it. There is likewise in Latin a small treatise or fragment, called "Adumbrations" on some of the Catholic epistles, which, if it be Clement's, was probably traslated from the same work called "Institutions," as we learn from Eusebius and others, containing short explications of many books both of the Old and New Testament. Many of the ancients speak in high terms of the excellent character and distinguished learning of Clement. Many testimonies to this purpose, collected from Eusebius, Alexander bishop of Jerusalem, St. Jerom, &c. may be seen prefixed to the Oxford or Potter's edition of St. Clement's works, in 2 vols. folio, 1715.

In the writings of Clement we have a very valuable testimony to the four gospels of St. Matthew, St. Mark, St. Luke, and St. John, all which were owned and received by him; and he has also preserved a tradition concerning the order in which they were written, which he had received from proselytes of more ancient times. We have also an assurance of the genuineness of the genealogies in the first chapter of St. Matthew and the third chapter of St. Luke; which he had also received from more ancient presbyters. "This testimony to the first chapter of St. Matthew's gospel is so strong," says Dr. Lardner, "that it seems to put the antiquity and genuineness of it out of question." Clement's account of the occasion of writing St. Mark's gospel agrees with that of Papias and Irenæus, which informs us that this gospel contains the substance of Peter's preaching; and that it was composed by one who had been long a companion and follower of Peter, and who retained in his memory the things that had been spoken by that apostle. Clement supposes that St. John, who wrote last, had seen and approved the other three gospels. He owns the Acts of the Apostles, and ascribes it to Luke as the author, who is said to have likewise translated the epistle to the Hebrews. He also admits all the fourteen epistles of Paul, except the epistle of Philemon; but his omitting to mention this epistle might be owing to its brevity. He also quotes the first epistle of Peter, the first and second epistles of John, the epistle of Jude, and the book of Revelation; but we have in Clement no quotations from the epistle of James, the second of Peter, or the third of John, nor any evidence that these were owned by him. The epistle of Barnabas, that of Clement of Rome, and the shepherd of Hermas, are quoted by Clement with higher marks of respect than others, as they are deserving of it on account of their early age, and their authors' acquaintance with the apostles or apostolical men. But he affords us no evidence that he had the same respect for them which he had for the gospels and the epistles of the apostles. There are also other books, called apocryphal, which are cited by Clement; such are the Gospels according to the

Hebrews,

Hebrews, and according to the Egyptians; the Preaching of Peter, the Revelation of Peter, and the Acts of Peter, and the Traditions of Matthias. But there is no sufficient reason for supposing, that St. Clement received as "Scripture," in the highest sense of the word, any Christian writings, besides the books of the New Testament, now commonly received by us. Cave's Hist. Lit. t. i. p. 88, &c. Fab. Bib. Græc. t. v. p. 102, &c. Lardner's Works, vol. ii. p. 206 – 243.

CLEMENT, a name assumed by several of the bishops of Rome. Of *Clement* I. we have already given an account under the article CLEMENS ROMANUS.

Clement II. was the name assumed by Suiger, a native of Saxony, and bishop of Bamberg, upon his elevation to the pontifical throne, in 1046, in order to supply the vacancy occasioned by the death of Gregory VI. On the day of his election he crowned Henry emperor, and his queen Agnes empress; and in a council speedily assembled at Rome, he issued several canons against simony, which had prevailed almost universally all over the West. In this council he settled a dispute between the archbishops of Ravenna and Milan concerning precedency; determining, by his apostolical authority, in favour of the former, whom he ordered always to sit on his right hand, unless the emperor should be present, and, in that case, to sit at his left. This pope died at Rome on the 9th of October 1047, after a pontificate of 9 months and 15 days; and his remains were interred at Bamberg. St. Wiborada, a virgin martyred by the Hungarians in 925, was canonized by this pope, and the day of her death appointed as an annual festival.

Clement III. was Paul, cardinal bishop of Palestrina, and a native of Rome, who, being elected at Pisa on the 19th of December, 1187, as successor to Gregory VIII. was crowned the next day under this name. Soon after his election, he exerted himself in terminating a contest that had subsisted for 50 years between the pope and the Roman people. Accordingly an agreement was concluded, in 1188, after several previous conferences, upon the following terms: *viz.* that the pope should be invested with the sovereignty of Rome:—that the office of patrician should be abolished, and a prefect with more limited power appointed in his room:—that senators should be created annually, with the approbation and by the authority of the pope, who should take an oath of allegiance to his holiness, and promise to assist him when required:—that St. Peter's church and its revenues should be restored to the apostolic see:—that the tolls and all other public revenues should be at the disposal of the pope, on condition that he expended one-third of them for the use of the Roman people:—that the senate and the people should reverence the majesty and maintain the honour and dignity of the high pontiff:—that the Roman pontiff should bestow the usual gifts and largesses upon the senators, judges, advocates, and other officers of the senate:—that he should pay yearly a certain sum for the reparation of the walls of the city:—and that he should allow the walls of Tusculum to be razed to the ground, and assist the Romans in that undertaking. The papal dominion over Rome being thus established, Clement set out from Pisa for Rome without delay, and was cordially received by the senate, the nobility, and the people. The pope, having secured his sovereignty, zealously engaged in the prosecution of the holy war, and left no attempt untried for inducing all Christian princes to unite in a new crusade. His active efforts were crowned with singular success not only in Italy but in Germany, France, and England; and heavy taxes were imposed in order to defray the expence of the intended expedition. In England, particularly, a tenth was exacted of all revenues, of all moveables and chattels. Having thus provided a large sum of money, a war in the east was carried on, though with little success, by Richard, the son and successor of Henry II., after the death of his father in 1189. Clement, having compromised the difference that subsisted between William king of Scotland and the apostolic see, and exempted the church of Scotland from all submission to the English church, and having enjoyed the satisfaction of hearing that the kings of France and England had departed for the Holy Land at the head of two numerous armies, was humbled and grieved by the unexpected news of the death of the emperor Frederic, who, after having adjusted all his differences with the apostolic see, had taken the cross, and obtained many signal advantages over the infidels. Whilst he was pursuing these advantages, he fell from his horse in crossing a river, and lost his life before his assistants could afford him any assistance. The pope did not long survive this distressing intelligence. He died on the 27th of March in the following year, *viz.* 1191, and, being greatly beloved by the Romans, was buried with extraordinary pomp in the Lateran church. Before his death, he canonized Otto, bishop of Bamberg, the first who preached the gospel to the Pomeranians, and Stephen de Mureto, founder of the order of the Grandimontenses.

Clement IV. succeeded Urban IV. in 1265. His family name was Guido, and he was a native of St. Gilles on the Rhone, in the province of Narbonne. In his youth he followed the military profession, and afterwards applied himself to the study of the law, with such assiduity and success, that he was reckoned one of the best civilians of his time. Upon the death of his wife he entered into holy orders; and after several gradations of ecclesiastical preferment, he was created by Urban IV. in 1261, cardinal bishop of Sabina; and in 1263, he was sent, under the character of the pope's legate *à latere*, into England, to mediate a reconciliation between the king and his barons, who were then at open war. But, being forbidden to enter the kingdom, he stopped at Boulogne, and, summoning thither some of the English bishops, he solemnly excommunicated, in their presence, all who should thenceforth disturb the public peace of the kingdom, and ordered the bishops to publish that sentence, and to see it executed. In his return to Italy, he received the news of his election to the papacy; and having arrived safe at Perugia, he was there, or, as some say, at Viterbo, consecrated and crowned, assuming the name of Clement, because he was born on St. Clement's day. Instead of following the example of other popes, who had enriched and aggrandized their families at the expence of the church, he gave his relations to understand, that they must expect nothing from him as pope, but content themselves with the wealth and the rank which they possessed before his promotion. Clement is said to have abhorred plurality of benefices, as a most scandalous abuse; and he obliged even his own nephew, who had three, to resign two of them, allowing him to choose which of the three he pleased. The character of Clement was, in many respects, unexceptionable; nevertheless, in conformity to the conduct of his predecessors, he made it the whole business of his pontificate, utterly to extirpate the family of Frederic, to drive Manfred from the kingdom of Sicily, and settle Charles of Anjou upon the throne. Charles was accordingly invested with the kingdom of Sicily by four cardinals appointed by the pope; but under so many conditions annexed to the investiture, that he became, in effect, a tributary of the apostolic see. On the 6th of January, 1266, Charles was solemnly crowned in the church of St. Peter, as king of Sicily on this and the other side of the Pharos, or the straits of Messina; and hence probably originated.

ginated the modern title of king of both Sicilies. His wife, Beatrix, who had long panted for a crown, received it at the same time. Charles, however, was obliged to contest the possession of the kingdom, first against Manfred, who was defeated and slain in battle, and afterwards against Conrad, or Conradin, who was invited by the discontented barons to possess himself of his paternal and hereditary kingdom, which the pope had unjustly wrested from him, and conferred upon one who had not the least shadow of right to it. Conradin, in defiance of the citations and menaces of the pope, entered Italy; and at Rome he was received by the senate, the nobility, and the people, with the greatest demonstrations of joy. These measures so enraged the pope, that he thundered out the sentence of excommunication against Conradin, and all who should assist him, accompanied with menaced forfeitures, and with a declaration, that Conradin himself was incapable of holding any kingdom, fief, or dignity whatever. The Romans, however, protected Conradin, and supplied his army, as long as he remained in their city, with all necessaries, at their own expence. One of his generals having gained a victory in Sicily, Conradin was proclaimed king in all the chief cities of the island, and the Sicilians every where declared for him. However, Conradin having heard of the victory, left Rome in order to engage Charles; and the two armies having met at the lake of Celano, engaged in a combat, which proved disastrous to Conradin, and terminated in a complete victory on the part of Charles. The consequence of this event was an order issued by Charles, that all the cities which had declared for Conradin, should be given up to be plundered, and then laid in ashes. The citizens who had taken part with the rebels, as they were called, were either put to a cruel death, or confined for life. Conradin himself was publicly executed, and several of his partizans, of distinguished rank, shared the same fate. Clement, however, did not live to hear of these barbarous executions. He died at Viterbo, in the latter end of November 1268; whereas Conradin was not beheaded till October 1269. Clement, exclusively of his conduct in the events above related, and his implacable and unprovoked enmity to Conradin and his family, pursued a conduct that merited commendation. He relieved poverty and distress, rewarded virtue and merit, and left his relations at his death in the same rank and condition they were in when he first ascended the pontifical throne. Several learned treatises upon the canons, and canon law, are ascribed to Clement. But some of these were undoubtedly written by one Guido Papa, who has been mistaken for pope Clement, whose name, before his promotion, was Guido. The life of Clement has been elegantly written by the Jesuit, Claudius Clemens, and was printed at Lyons in 1629.

Clement V. was elected the successor of Benedict XI., after a contest in the conclave of cardinals which lasted near a year, in the year 1305. He was the son of Berald de Got, a nobleman of Aquitain, and, by favour of Boniface VIII. preferred in 1299 to the archbishopric of Bourdeaux. The ceremony of his coronation was performed at Lyons, whither he summoned the cardinals; and, on his return from the church of St. Justus to his palace, with the crown on his head, his horse was led part of the way by the king of France on foot, and afterwards by Charles de Valois and the duke of Brittany, likewise on foot. But the fall of a wall during the procession, which killed several persons of distinction, and caused the crown to fall from the head of the pope, excited a great alarm among the people, and gave occasion to the Italian writers to observe, that such were the auspices under which the holy see was translated from Italy to France, from Rome to Avignon, where it remained for an interval of more than 70 years. The first and chief care of Clement, after his elevation, was to fulfil his engagements to the French king, thus recompensing him for the effectual service which he had rendered in promoting his election. Besides the creation of 10 cardinals, all of whom were Frenchmen, and the restoration of the two Colonnas to the cardinalate, from which they had been degraded; he granted to the king the tenths of all the ecclesiastical revenues in his kingdom, for the space of 5 years; and he revoked and annulled a law, which declared, that the kingdom of France, and of course all other kingdoms, are subject to the see of Rome in temporals, as well as spirituals. In the year 1309, the pope transferred his see to Avignon, which was at that time subject to Charles, king of Sicily; and in 1311 he summoned a general council at Vienne, in order to determine with regard to the knights templars, who were charged with many enormous crimes, to procure immediate relief and supply for the Christians in the Holy Land, to reform the manners of the ecclesiastics, and to restore the decayed discipline of the church. The prosecution against the knights templars was carried on in different countries under the authority of the pope, and the order was suppressed by him in a private consistory in the year 1312. See KNIGHTS TEMPLARS. At the third session of this council, an order was issued for preaching a new crusade through all Christian countries, and great indulgences were granted to all who should engage in it. In the same session, the doctrines of the Beguardi and Beguines were condemned; and the constitution of Gregory X. relating to the conclave, confirmed by Celestine V. and Boniface VIII., was confirmed anew by this council; and it was further ordained, that no cardinal, under any pretence of excommunication, suspension, or interdict whatever, should be excluded from the election. In the year 1313, after the breaking up of this council, Celestine V. was canonized by the pope. Among the last acts of his pontificate, were the coronation of Henry VII. as emperor, and the creation of Robert king of Sicily, a senator of Rome, and a vicar of the empire. Soon after these events Clement died, at a place called Requemaure, in the diocese of Nismes, in his way to Bourdeaux, his native place, on the 20th of April 1314, (or as others say, 1316) when he had held the see from the day of his election, on the 5th of June 1305, 8 years, 10 months, and 15 days. The ambition of this pontiff was unbounded; and he acted during his whole pontificate as a mere tool of the French king, to whom he had owed his promotion. Clement wrote many constitutions relating to different subjects, and ordered them to be distinguished by the title of "The Seventh book of the Decretals." Since his time they have been known by the name of "The Clementines;" they were approved by the council of Vienne, and published by Clement at Montil, not long before his death, that is, on the 21st of March, 1314. As he was prevented by his illness and death, that soon ensued, from sending them to the universities; they remained in a manner suspended till the year 1317, when his successor, John XXII, sent authentic copies of them to all the universities, ordering them not only to be taught in the schools, but to be quoted, as standing laws, in the courts of justice. See CANON *Law*.

Clement VI. succeeded Benedict XII. and was crowned on the 19th of May 1342. His family name was Peter Roger. He was born in 1292, in the diocese of Limoges, and embraced a religious life among the Benedictines at the age of 10 years; having studied at Paris, and being admitted by the university of that city, at the age of 30, to the degree of master or doctor in divinity, he rose through several subordinate gradations of preferment to that of cardinal

 presbyter

presbyter of St. Nereus and Achilleus, to which rank he was advanced in 1338 by pope Benedict XII. Soon after his election he created 10 new cardinals, among whom was his brother Hugh Roger, who refused the pontificate upon the death of Innocent VI. The Romans congratulated him on his elevation to the papal see by a solemn embassy, and requested that he would reside at Rome, and order the jubilee to be celebrated every 50th year. They also conferred upon him, as Peter Roger, the supreme magistracy, but not as pope, least his predecessors should claim it. One of the deputies on this occasion was the celebrated Petrarch, who was very favourably received. Although he declined for the present complying with their request of residence at Rome, he ordered a jubilee according to their desire. Differences having subsisted for a long time between the emperor Lewis and the apostolic see, an embassy was sent by the emperor to the pope in the second year of his pontificate, proposing an accommodation and requesting absolution. Clement received the embassadors in a very haughty manner, and having advised with his cardinals, proposed, as the only terms of absolution, that he should own himself guilty of the heresies, with which he was charged, and abjure them all; that he should surrender the title of king or emperor, resign the government of the empire, and not resume it without the permission of the apostolic see; that he should submit to the absolute disposal of the pope himself, his children, and all his hereditary dominions and estates; and that he should acknowledge the empire to be in the gift of the apostolic see. These articles, however humiliating to the emperor, were agreed to by the ambassadors; and the emperor, astonished at the extravagant demands of the pope, resolved to improve them to his own advantage. Accordingly he sent copies of them to all the princes and states of the empire, and convoked a diet at Frankfort for the purpose of deliberating, concerning the most proper means of defeating the ambitious views and effectually resisting the encroachments of the pope. At this diet it was agreed, that these terms of conciliation should be rejected by the German states and princes. The pope, incensed at their refusal, confirmed all the sentences that had been pronounced against the emperor by his predecessor pope John, or himself, and ordered the electors to proceed immediately to the election of a new king of the Romans: Lewis of Bavaria having forfeited, "as an avowed and impenitent heretic," all right to that title and to the imperial crown, and to every other kind of dignity. This order was accompanied with the recommendation of Charles duke of Moravia, the son of John king of Bohemia, after he had previously stipulated the conditions on which his interest was to be employed in advancing the duke to the Imperial throne. The electors complied; Charles was elected; and the election was ratified by the pope's bull, issued Nov. 6th, 1346. About this time a revolution happened in the kingdom of Naples, which was occasioned by the murder of the king, in consequence of which the kingdom was invaded by the king of Hungary, the brother of the deceased sovereign. Upon this invasion queen Joan retired from the kingdom and repaired to Avignon in order to plead her cause before the pope and the cardinals. This she did with such effect, that Clement dispatched an apostolic legate into Hungary to negotiate a reconciliation between Joan and her husband, Lewis of Taranto, and the Hungarian king. In the meanwhile the Neapolitan nobility, who had become weary of the government of the Hungarians, invited Joan back to her own kingdom; who, in order to furnish herself with money for defraying the charges of her expedition, sold Avignon to the pope for 80 thousand florins of gold. The bargain was confirmed by Charles, who had been lately elected king of the Romans, and also renounced all the right claimed by the empire over that city and its territory. The bull containing this renunciation is dated Nov. 1, 1348. In this year a very dreadful plague raged over all Europe; and in this general calamity Clement was liberal and active in affording the sufferers necessary and seasonable relief. In 1349, a new sect arose called the "Flagellants;" but, being threatened excommunication by the pope, they were very soon extirpated. On occasion of the jubilee, which took place in the year 1350, Rome was crowded with pilgrims; and the number that thronged thither was so great, that one would have thought, says Petrarch, who was present, that the plague which had almost unpeopled the world, had not so much as thinned it. The pope distinguished himself by his active endeavours in restraining the exactions and oppressions which the pilgrims suffered from the cruelty and avarice of the Romans. In Germany many of the princes and cities refused to acknowledge Charles, who had been imposed upon them by the interference and influence of the pope; and actually proceeded to elect another emperor in his room. After some unsuccessful efforts for this purpose, the Germans, tired out with a long war, chose rather to submit to Charles than to involve their country in new troubles by new elections. In 1351, Clement undertook the defence of the mendicant friars, that had been eminently useful during the plague, and to whom many had left their estates in recompence of their services, against the secular clergy, who complained to the pope of their having degenerated from their original institution, and demanded the entire suppression of that order. At the close of this year Clement was taken dangerously ill, and the cardinals, apprehending the event of his death, prevailed upon him to mitigate the rigour of the constitution of Gregory X. with respect to the conclave. (See CONCLAVE.) During the same malady he issued another constitution, importing that if in disputing, preaching or teaching, either before or since his promotion to the apostolic see, he had advanced any thing contrary to the catholic doctrine, as to good morals, he retracted it; and submitted the whole to the judgment of his predecessors; and hence we perceive that he entertained but an indifferent opinion of his own infallibility. Having in the following year dispatched a legate into Sicily to crown Joan queen of Jerusalem and Sicily, and her husband Lewis king, Clement, towards the close of the year, was seized with a fever, which terminated his life on the 6th of December, after he had held the Roman see, from the day of his coronation, 10 years six months and 18 days. This pope was fond of pomp and grandeur, and lived more like a monarch than a bishop. It was his favourite object to aggrandize his family, and enrich his relations, several of whom he furnished with estates in France, and others of them he made cardinals, though they were under the stipulated age, or led scandalous lives. In his promotions, it is said, that he paid little respect to learning or virtue. Petrarch speaks of him as possessing an uncommon memory, so that he never forgot any thing he had read or heard, as a person of very great learning, and as no less eloquent than learned. He is said, by some of his biographers, to have preached frequently, and to have composed many excellent sermons. The only writings of Clement, extant in print, are a treatise on ecclesiastical power, some speeches, letters, decretals, and a book upon the canonization of St. Ivo, which took place in 1347. Among other acts of his pontificate he granted to the kings of France the privilege of receiving the sacrament in both kinds, whenever they pleased; he appointed Lewis, earl of Clermont, descended from

from the royal families of France and Castile, king of the Fortunate islands, now the Canaries, which were discovered in his time, for which grant he obliged Lewis and his heirs to pay yearly 400 florins of gold to him and his successors, as an acknowledgement of their holding their kingdom of the apostolic see; he disposed of some rich benefices in England to foreigners, which in 1343 occasioned a quarrel between him and Edward III.; he embellished, at a great expence, the pontifical palace at Avignon; and, exclusively of other charities, he founded at Rouen, and richly endowed a college, called the "Pope's College," or the college of "Clementine Priests."

Clement VII. was the name assumed by the cardinal de Medici, who succeeded Adrian VI., Nov. 28, in the year 1523. This choice, after a contest in the conclave which lasted fifty days, was universally approved. High expectations were formed of a pope, whose great talents, and long experience in business, seemed to qualify him no less for defending the spiritual interests of the church, exposed to imminent dangers by the progress of Luther's opinions, than for conducting its political operations with the prudence requisite at such a difficult juncture; and who, besides these advantages, rendered the ecclesiastical state more respectable by having in his hands the government of Florence, together with the wealth of the family of Medici. By this election the ambitious views of cardinal Wolsey, who aspired to the papal throne, were a second time disappointed; notwithstanding the interest employed in his favour by Henry VIII. with the emperor Charles V., and the activity of Wolsey himself, who instructed his agents at Rome to spare neither promises nor bribes in order to gain his end. The cardinal, after all his expectations and endeavours, had the mortification to see a pope elected of such an age, and of so vigorous a constitution, that he could derive little comfort from the chance of succeeding him. Wolsey was extremely indignant on the occasion; and though Clement endeavoured to soothe his vindictive nature by granting him a commission to be legate in England during life, with such ample powers as vested in him almost the whole papal jurisdiction in that kingdom, the injury he had received entirely dissolved the tie, which had united him to Charles, and from that moment he meditated revenge. However he had art enough to disguise his resentment; and he abounded on every occasion, private as well as public, in declarations of his high satisfaction with Clement's promotion. Clement had scarcely taken secure possession of the pontifical chair, before ambassadors were sent to him both by the emperor and the king of France, then at war in the Milanese, to engage him in their interest. The pope, however, instead of taking a decisive part with either of the contending parties, laboured with the zeal which became his character, to bring about a reconciliation; but his endeavours were ineffectual. The war was pursued with greater vigour than ever, and the French were expelled both out of the Milanese and the republic of Genoa; but Francis, the king of France, having gained considerable advantages over the Imperialists, who had invaded Provence and laid siege to Marseilles both by sea and land, and compelled them to abandon his dominions, crossed the Alps at mount Cenis, and advancing rapidly into the duchy of Milan, made himself master of that capital, and laid siege to Pavia. The pope, who already considered the French as superior in Italy, became impatient to disengage himself from his connections with the emperor, of whose designs he was extremely jealous, and to enter into terms of friendship with Francis. He laboured hard to bring about a peace that would secure Francis in possession of his new conquests; and as Charles, who was always inflexible in the prosecution of his schemes, rejected the proposition with disdain, and with bitter exclamations against the pope, by whose persuasion, while cardinal de Medici, he had been induced to invade the Milanese; Clement immediately concluded a treaty of neutrality with the king of France, in which the republic of Florence was included. Whilst the siege of Pavia was slowly carried on, the Imperialists attacked the French with a very powerful force, defeated them in what is called the battle of Pavia (Feb. 24, 1525) with great slaughter, and took the king prisoner. This victory excited the greatest alarm among the Italian states, and Clement, instead of pursuing the measures which he had concerted with the Venetians for securing the liberty of Italy, either intimidated by threats or allured by promises, entered into a separate treaty with Charles, binding himself to advance a considerable sum in return for certain emoluments which he was to receive. The money was instantly paid; Charles afterwards refused to ratify the treaty; and the pope remained exposed at once to infamy and ridicule; to the former, because he had deserted the public cause for his private interest; to the latter, because he had been a loser by that unworthy action. In the year 1526, an alliance was concluded between the pope, the Venetians, and Sforza, duke of Milan, for the security and liberty of Italy. The king of France, who had been released from captivity, and Henry VIII., king of England, acceded to it. The latter was declared protector of this league, which they dignified with the name of "holy," because the pope was at the head of it; and in order to allure them more effectually, a principality in the kingdom of Naples, of 30,000 ducats yearly revenue, was to be settled on him, and lands to the value of 10,000 ducats on his favourite Wolsey. Clement, as soon as this league was concluded, by the plenitude of his papal power, absolved Francis from the oath which he had taken to observe the treaty of Madrid, which had been the stipulated condition of his release; but the discovery of Francis's intentions to elude this treaty filled the emperor with a variety of disquieting thoughts, and he determined to insist on the strict execution of it. As soon also as he had received an account of the holy league, he exclaimed against Francis, as a prince void of faith and of honour; nor did he less complain of Clement, whom he solicited in vain to abandon his new allies. He, moreover, threatened him not only with all the vengeance which the power of an emperor could inflict, but by appealing to a general council, called up before him all the terrors arising from the authority of these assemblies, so formidable to the papal see. At the same time he exerted himself with unusual vigour, in order to send supplies not only of men, but of money, which was still more needed, into Italy. The Colonnas, who retained their attachment to the Imperial interest, and who, by placing themselves under the protection of the emperor, preserved the quiet possession of their own territories and privileges, took an active part against the confederacy, and particularly against the pope; and after for some time amusing and deluding him, marched to Rome, and made themselves masters of the city. Clement, terrified at the danger that threatened him, ashamed of his own credulity, and deserted by almost every person, fled with precipitation into the castle of St. Angelo, which was immediately invested. After a general plunder of the Vatican, the church of St. Peter, and the houses of the pope's ministers and servants, Clement, deprived of every thing necessary for subsistence or defence, was soon obliged to demand a capitulation; and the Imperial ambassador, Moncada, with the haughtiness of a conqueror, prescribed conditions, which it was not in his power to reject. The chief of these was, that Clement should not only grant a full pardon to the Colonnas, but receive them into favour, and immediately withdraw all the

 troops

troops in his pay from the army of the confederates in Lombardy.

The Colonnas, who talked of nothing less than deposing Clement, and of placing Pompeo, their kinsman, in the vacant chair of St. Peter, exclaimed loudly against a treaty, which left them at the mercy of a pontiff justly incensed against them. But Moncada, attentive merely to his master's interest, paid little regard to their complaints, and by this fortunate measure, broke intirely the power of the confederates. Clement, regardless of the treaty with Moncada, degraded the cardinal Colonna, excommunicated the rest of the family, seized their places of strength, and wasted their lands with all the cruelty excited by a recent injury. After this he turned his arms against Naples, and as his operations were aided by the French fleet, he made some progress towards the conquest of that kingdom; the viceroy being no less destitute than the other Imperial generals of the money requisite for a vigorous defence. The Colonnas and the other friends of the emperor soon retaliated on the pope; for the duke of Bourbon who commanded the Imperial army, wanting money to pay his troops and to purchase provisions for their subsistence, determined to force his way into the State of the Church, and to let his army live upon plunder. However, he concealed his intentions so succesfully, that Clement, though alarmed, could not discover whether Rome or Florence would be the first object of his depredation; and he was therefore kept for some time in a state of disquieting suspenee. Thus circumstanced, the pope concludes an agreement with Lannoy, viceroy of Naples, March 15, 1527, comprehending the following principal articles, *viz.* that a suspension of arms should take place between the pontifical and Imperial troops for eight months; that Clement should advance 60,000 crowns towards satisfying the demands of the Imperial army; that the Colonnas should be absolved from censure, and their former dignities and possessions be restored to them; and that the viceroy should come to Rome, and prevent Bourbon from approaching nearer to that city, or to Florence. On this treaty Clement fixed his reliance; a reliance which Guicciardini ascribes wholly to an infatuation which those who are doomed to ruin cannot avoid. Lannoy having thus detached Clement from the confederacy, wished to turn Bourbon's arms against the Venetians; but Bourbon had other schemes to accomplish. Although he received a message from the viceroy he paid no regard to it, but continued to ravage the ecclesiastical territories, and to advance towards Florence. Upon this Clement renewed his application to Lannoy, and intreated and conjured him to put a stop to Bourbon's progress. Lannoy made some ineffectual efforts for this purpose; but Bourbon's soldiers, having heard of the truce, raged and threatened, demanding the accomplishment of the promises in which they had confided. Whilst every person in Rome perceived the approaching and irresistible storm, Clement alone, relying on some ambiguous and deceitful professions which Bourbon made of his inclination towards peace, sunk back into his former security. Bourbon being under a necessity of changing his rout towards Florence by the arrival of the duke d'Urbino's army, determined to attack and plunder Rome. The resolution was bold, and the execution of it no less rapid. Clement was rouzed from his security; and though, under his feeble conduct, all was consternation, disorder, and irresolution, yet he collected such of his disbanded soldiers as still remained in the city; he armed the artificers of Rome, and the footmen and train-bearers of the cardinals; he repaired the breaches in the walls; he began to erect new works; he excommunicated Bourbon and all his troops, branding the Germans with the name of Lutherans, and the Spaniards with that of Moors. Thus prepared, he determined to wait the approach of an enemy whom he might easily have avoided by a timely retreat. Bourbon advanced with speed, and encamped in the plains of Rome on the evening of the 5th of May. Having animated his soldiers by presenting to their view the palaces and churches of the capital of the Christian commonwealth, into which the wealth of all Europe had flowed during many centuries, without having been violated by any hostile hand, he commenced the assault early on the next morning, and at the head of his troops he led them to scale the walls. They were at first received with a fortitude equal to their own; and whilst Bourbon's troops were ready to give way, their leader threw himself from his horse, seized a scaling ladder from one of the soldiers, and as he began to mount it, a musket ball from the ramparts gave him a deadly wound, which, at the moment of expiring, he endeavoured to conceal from his troops. As soon as this fatal event was known to the army, it seemed to animate them with new valour; the name of Bourbon resounded along the line, accompanied with the cry of blood and revenge. The veterans on the walls were overpowered, the enemy rushed on with incredible violence, and the city was taken. During the combat, Clement was employed at the altar of St. Peter's in offering up to heaven unavailing prayers for victory. But as soon as he heard that his troops began to give way, he fled with precipitation; and instead of making his escape, such was his infatuation, he shut himself up, with thirteen cardinals and others, in the castle of St. Angelo, which he had before found to be an insecure retreat. The misery and horror of the scene that followed may be more easily conceived than described. The pillage and cruelty that were exercised on this occasion exceeded those of the Huns, Vandals, or Goths, in the 5th and 6th centuries. The booty in ready money alone amounted to a million of ducats; and what they raised by ransoms and exactions far exceeded that sum. Clement himself, deprived of every resource, and reduced to such extremity of famine as to feed on asses' flesh, was obliged to capitulate on such conditions as the conquerors were pleased to prescribe. He agreed to pay 400,000 ducats to the army; to surrender to the emperor all the places of strength belonging to the church; and, besides giving hostages, to remain a prisoner himself until the chief articles were performed. The emperor feigned grief for the plunder of Rome, and the captivity of the pontiff; but it was, without doubt, mere hypocrisy. The concern felt by the kings of France and England on this occasion was more sincere; though perhaps not altogether disinterested. Francis and Henry, alarmed at the progress of the Imperial arms in Italy, had, even before the taking of Rome, entered into a closer alliance; this alliance was now cemented by the common desire of rescuing the pope out of the emperor's hands, a measure no less political than it appeared to be pious. With this view they perceived the necessity of abandoning their designs in the Low Countries, and of rendering Italy the seat of war, that they might thus deliver Rome and set Clement at liberty. Wolsey neglected no measure that could incense his master against the emperor. Besides these considerations of a public nature, Henry was influenced by a more private and selfish motive; because he had begun about this time to form his scheme of divorcing Catharine of Arragon, towards the execution of which he knew that the sanction of papal authority would be necessary; and he was therefore desirous of acquiring as much merit as possible with Clement, by appearing to be the chief instrument of his deliverance.

In the mean while, whilst the two kings were negociating their new alliance, the pope, unable to fulfil the conditions of his capitulation, remained a prisoner. The Florentines, as soon as they heard of his captivity, ran to arms in a tumultuous manner; expelled the cardinal de' Cortona, who governed their city in the pope's name; defaced the arms of the Medici; demolished the statues of Leo and Clement; and declaring themselves a free state, re-established their ancient popular government. The Venetians, taking advantage of the calamity of their ally the pope, seized Ravenna, and other places belonging to the church, under pretext of keeping them in deposit. The dukes of Urbino and Ferrara likewise laid hold on part of the spoils of the unfortunate pontiff, whom they considered as irretrievably ruined. At length, however, the progress of the confederates in Italy and other political considerations induced the emperor to concert measures for setting the pope at liberty. As he wanted a large supply of money, he thought of the resource which presented itself in the ransom of Clement. The pope himself had contrived to disarm the resentment of cardinal Colonna, and he had also by favours and promises gained Moroné, chancellor of Milan; and by the address and influence of these two men the treaty for his liberty was the more speedily concluded, upon the following conditions. He was obliged to advance 100,000 crowns for the use of the army, to pay the same sum at the distance of a fortnight, and at the end of three months 150,000 more. He engaged not to take part in the war against Charles, either in Lombardy or Naples; he granted him a crusade, and a tenth of ecclesiastical revenues in Spain; and he not only gave hostages, but put the emperor in possession of several towns, as a security for the performance of these articles. Having raised the first moiety by a sale of ecclesiastical dignities and benefices, and other expedients equally uncanonical, a day was fixed for his release. But Clement, impatient to be free, after a confinement of six months, and indulging the suspicion and distrust natural to the unfortunate, was so fearful of fresh obstacles on the part of the Imperialists, that he disguised himself the preceding night in the habit of a merchant, and made his escape undiscovered. Before next morning he arrived at Orvieto, and from thence wrote a letter of thanks to Lautrec, the commander of the French troops, as the chief instrument of procuring him liberty. Afterwards Clement, though he always acknowledged his being indebted to Francis for the recovery of his liberty, and often complained of the emperor's cruel treatment, was not influenced by gratitude, nor was he swayed by the desire of revenge. Whilst he amused Francis with promises, he secretly negociated with Charles; and in June 1529, he had the address and diligence to get the start of his allies, by concluding, at Barcelona, a particular treaty for himself. The terms were more favourable than Clement could have reason to expect. Among other articles, the emperor engaged to restore all the territories belonging to the ecclesiastical states; to re-establish the dominion of the Medici in Florence; to give his natural daughter in marriage to Alexander, the head of that family; and to put it in the pope's power to decide concerning the fate of Sforza, and the possession of the Milanese. In return for these ample concessions, Clement gave the emperor the investiture of Naples, without the reserve of any tribute, but the present of a white steed in acknowledgment of his sovereignty; absolved all who had been concerned in assaulting and plundering Rome; and permitted Charles and his brother Ferdinand to levy the fourth of the ecclesiastical revenues throughout their dominions. The dissensions already mentioned between the pope and the emperor proved extremely favourable to the progress of Lutheranism. Charles, exasperated by the conduct of Clement, and fully employed in opposing the league which he had formed against them, had little inclination and less leisure to take any measures for suppressing the new opinions in Germany. In a diet of the empire held at Spires, June 25, 1526, the state of religion came to be considered, and all that the emperor required of the princes was, that they would wait patiently, and without encouraging innovations, for the meeting of a general council which he had demanded of the pope. They acquiesced; but to his advice, concerning the discouragement of innovations, they paid so little regard, that even during the meeting of the diet at Spires, the divines who attended the elector of Saxony and landgrave of Hesse-Cassel thither, preached publicly, and administered the sacraments, according to the rites of the reformed church. The emperor's own example emboldened the Germans to treat the papal authority with little reverence. A manifesto against the pope, little inferior in virulence to the invectives of Luther himself, was industriously dispersed over Germany; and being eagerly read by persons of all ranks, much more than counterbalanced the effect of all Charles's declarations against the new opinions. (See LUTHER and REFORMATION.) Soon after the conclusion of the pope's treaty with Charles, they had an interview at Bologna. On this occasion the emperor, at the head of 20,000 veteran soldiers, able to give law to all Italy, kneeled down to kiss the feet of that very pope whom he had so lately detained a prisoner. After the re-establishment of the authority of the Medici at Florence in 1530, the publication of the peace at Bologna, and the ceremony of his coronation as king of Lombardy and emperor of the Romans, which the pope performed with the accustomed formalities, Charles prepared for his journey into Germany. During the long residence of the emperor and pope at Bologna, they held many conferences concerning the most effectual means of extirpating the heresies which had sprung up in Germany. Clement dissuaded the emperor from convening a general council; Charles, on the contrary, thought the convocation of a council no improper expedient for reconciling the Protestants; but promised, that if these gentler arts failed of success, he then would exert himself with vigour in reducing those stubborn enemies of the Catholic faith. For the measures which he pursued, see REFORMATION, AUGUSTAN *Confession*, and AUGSBURG.

Charles, in his way to Spain in 1532, had another interview with the pope at Bologna. On this occasion they differed with regard to the expediency of calling a general council. Charles urged the salutary effects of such a measure, whilst Clement, by all the artifices in his power, attempted to delay, in hopes of thus entirely defeating, the convocation of such an assembly. Besides the negotiation with Clement about calling a council, the emperor carried on another, of greater importance in his estimation, for securing the peace established in Italy. With this view he proposed that the Italian states should enter into a league of defence against all invaders, and that, when danger occurred, an army should be raised and maintained at the common charge. The proposal was not unacceptable to Clement; accordingly a league was concluded; and all the Italian states, the Venetians excepted, acceded to it. At this interview the emperor is said to have proposed a match between Sforza, the duke of Milan, and Catharine de Medici the daughter of the pope's cousin Laurence de Medici; but this match was rejected by the pope; and another was negotiated by Francis and Clement between Henry, the

king

king of France's second son, duke of Orleans, and Catharine. Clement was so highly pleased with an honour which added such lustre and dignity to the house of Medici, that he offered to grant Catharine the investiture of considerable territories in Italy by way of portion; he seemed ready to support Francis in prosecuting his ancient claims in that country; and consented to a personal interview with that monarch. Charles's jealousy was excited by this proposed interview, and he could not bear that Clement, after he had twice condescended to visit him in his own territories, should confer such a distinction on his rival, as to venture on a voyage by sea, at an unfavourable season, in order to pay court to Francis in the French dominions. But the pope's rashness to accomplish the match overcame all scruples of pride, or fear, or jealousy, by which he was likely to be influenced on any other occasion. The interview, notwithstanding several artifices of the emperor to prevent it, took place at Marseilles with extraordinary pomp, and demonstrations of mutual confidence; and the marriage, which the ambition and abilities of Catharine (See CATHARINE) rendered in the sequel as fatal to France, as it was then thought dishonourable, was consummated. The pope and Francis, however, were so careful to avoid giving any cause of offence to the emperor, that no treaty was concluded between them; and even in the marriage-articles Catharine renounced all claims and pretensions in Italy, except to the duchy of Urbino. Whilst Clement was carrying on these negotiations and forming a connection with Francis, which gave so great offence to the emperor, such were the artifice and duplicity of his character, that he suffered the latter to direct all his proceedings with regard to the king of England. Henry's suit for a divorce from Catharine of Arragon (See that article), had now continued six years, during which period the pope negotiated, promised, retracted, and concluded nothing. Cranmer's sentence annulled the king's marriage with Catharine; her daughter was declared illegitimate; and Anne Boleyn acknowledged queen of England. Henry, displeased with the conduct of Clement, began to make innovations in the church, of which he had formerly been such a zealous defender. Clement, who had already seen so many provinces and kingdoms revolt from the holy see, became apprehensive lest England should follow their example, and partly from his solicitude to prevent that evil, and partly in compliance with the French king's solicitations, he determined to give Henry such satisfaction as might still retain him within the bosom of the church. But the violence of the cardinals, devoted to the emperor, did not allow the pope leisure for executing this prudent resolution, and hurried him, with a precipitation fatal to the Roman see, to issue a bull, rescinding Cranmer's sentence, enforcing Henry's marriage with Catharine, and declaring him excommunicated, if, within a time specified, de did not abandon the wife he had taken, and return to her whom he had deserted. The consequence of this measure is well known. Henry was enraged; his subjects concurred in his indignation; an act of parliament was passed, abolishing the papal power and jurisdiction in England; by another act, the king was declared supreme head of the church; and all the authority of which the popes were deprived was vested in him. A short delay might have prevented the unhappy consequences to the see of Rome of Clement's precipitance. Soon after his sentence against Henry, he fell into a languishing distemper; which terminated his life after he had lived 56 years 4 months, on the 25th of September, 1534, and his pontificate, after a duration of 10 years, 10 months, and 7 days; the most unfortunate, both whilst it continued and in its effects, that the church had known for many ages. He died hated by the court, suspected by the princes, and generally reputed a man of no faith, and naturally averse from doing any man a good office. He was grave, circumspect in all his actions, much master of himself, a great dissembler, and endowed with excellent parts, and uncommon penetration. But the extreme timidity to which he was subject after his imprisonment seldom allowed him to make a free use of his own judgment. During his pontificate he created 31 cardinals; but none, his nephew Hyppolitus de Medici excepted, of his own choice; the rest he raised to that dignity, against his will, to gratify those, who recommended them, especially the emperor and the king of France. Bower's Hist. of the Popes, vol. vii. Robertson's Hist. ch. v. vols. ii. and iii.

Clement VIII. was the name assumed by Hippolito Aldobrandini, cardinal of St. Pancras, a Florentine, when he succeeded Innocent IX. in the see of Rome. He was chosen Jan. 30, 1592, and crowned on the 2d of February following. His pontificate is chiefly remarkable for the three following events; the conversion, absolution, and reconciliation of Henry IV. of France in 1595; the reversion of the dechy of Ferrara to the apostolic see, upon the death of duke Alphonsus II. in 1597; and the peace, concluded at Vervins in 1598, between France and Spain, by the mediation of Clement. The famous controversy between the Jesuits and Dominicans, concerning grace, free-will, and predestination, arose in the time of this pope, and was likely to produce fatal divisions in the church. This controversy was carried on with great asperity and violence till the year 1594, when Clement imposed silence on the contending parties, promising to examine the points in dispute. For this purpose he appointed a particular congregation, called "De Auxiliis" or of aids; but as nothing had been determined by this body in 1602, the pope resolved to preside at it in person, and he accordingly heard both parties with the greatest attention and patience. But as each ably defended the cause with great zeal and dexterity, Clement, not chusing to exercise his infallibility, lest he should disoblige one or other of the two most learned orders of the church, left the final decision of the points in dispute to his successor. He died March 3, 1605, after having presided in the see 13 years, one month, and three days. This pope has been represented by cotemporary writers as a man of uncommon abilities and of great prudence. It was by the urgent interference of this pope, that the Jesuits, who had been expelled France upon the murder of Henry III. were restored in 1603 by his successor Henry IV. Bower vol. vii. Mosheim E. H. vol. v.

Clement IX. and *Clement* X. were elected successively to the papacy in the years 1667 and 1670; but they were concerned in few transactions that deserve to be transmitted to posterity. The former was of the family of Rospigliosi, and several instances of his conduct are recorded that do him honour, and prove his dislike of nepotism, and his love of peace and justice. His pontificate commenced in 1667 and terminated in 1670; that of his successor closed in 1676. Mosheim.

Clement XI. was the name assumed by John Francis Albani, when he was raised to the head of the Roman church in the year 1700. He surpassed in learning the whole college of cardinals, and was inferior to none of the preceding pontiffs in sagacity, lenity, and a desire, at least, to govern well; but he was very far from opposing, with a proper degree of vigour and resolution, the inveterate corruptions and superstitious observances of the church over which he presided; on the contrary, he inconsiderately aimed at, what he thought, the honour and advantage of the church (that is, the glory and interest of its pontiff), by measures that proved detrimental to both, and thus shewed, by a striking example, that popes, even of the best sort, may fall imperceptibly into the greatest mistakes, and commit the most pernicious blunders, through an imprudent zeal for extending their jurisdiction, and augmenting the influence and lustre of their station. His pontificate closed in 1721. Mosheim.

Clement XII. began his pontificate in 1730, and terminated it in 1740.

Clement XIII. was elevated to the papacy in 1758, and held it till the year 1765.

Clement XIV. commenced his pontifical office in 1769, and closed it in 1775.

Clement, John, received his education at Oxford, where he made such progress in the knowledge of the Greek and Latin languages, as to attract the notice of sir Thomas More, who took him into his family to instruct his children. By the recommendation of sir Thomas, he was invited to settle in Corpus Christi college, Oxford, and appointed professor in rhetoric, in the year 1519, and soon after, to succeed to Linacre in the Greek professorship. It may not be improper to mention, that the first two public teachers of the Greek language at Oxford were physicians, for Clement, probably incited by the fame acquired by his predecessor, applied himself diligently to the study of medicine, which he practised with success. He was soon after made fellow of the Royal College of physicians, lately established in London. In 1529, he was ordered by his sovereign, Henry VIII. to attend cardinal Wolsey, who was dangerously ill at Esher; but the malady of that great statesman was not removeable by medicine. On the accession of king Edward VI., Clement, with a few other catholics, was excepted from the general pardon granted by that prince; he therefore went to Mechlin. What drew on him this severe treatment is not known, unless it was his rigid attachment to the Romish religion, which he imbibed while residing in the house of his patron sir Thomas More. On the death of Edward he returned to England, and resumed the practice of medicine in a part of Essex, near London. In this place he continued during the reign of queen Mary. On her demise he again migrated to Mechlin, where he died July 1, 1572. Of his medical knowledge he has left no memorial, his only works being some translations of pieces of divinity, and a book of Latin epigrams and other verses, now little known. Aikin's Biog. Sketches of Medicine.

Clement, Julian, a celebrated accoucheur, who contributed largely towards the improvement of the art of midwifery, was a native of Arles, in the department of the Rhone. It was there he received the rudiments of his education; but he was at an early age sent to Paris, and placed under the direction of James la Fevre, who then enjoyed considerable reputation for his skill in the practice of surgery, particularly that branch of it which teaches the method of delivering women in difficult labours. In time he succeeded to the practice of Le Fevre, whose daughter he had married. In December, 1663, he was called to assist the duchess de la Valiere; but as it was not usual at that time to employ men in this office, except in cases of difficulty or danger, the duchess is said to have removed to a private house, and even to have received him in a mask, so that he was not apprised of the quality of the lady he was attending. His success in this case was so agreeable to the king, Lewis XIV., that he was appointed accoucheur to the princesses of France, with a considerable pension. This circumstance, and his being employed in the subsequent labours of the duchess, and of many of the principal ladies about the court, added greatly to his popularity, and had a powerful influence in introducing the custom, which soon became general, of employing men to attend women in child-birth, instead of one of their own sex. Clement soon saw the absurdity of treating lying-in women as diseased persons, and introduced several salutary regulations for the women and children, particularly those of abridging the time of confinement of the women, and allowing a freer introduction of air into the room than had been before permitted. He also simplified and improved the method of turning the fœtus, in certain cases of wrong presentation, and first suggested the propriety of breaking the membranes early in labour, in cases of hæmorrhage, which was afterwards so successfully practised by his pupil and assistant, Puzos. The reputation of Clement became by these means, and by the general success of his practice, so great, that he was sent for to Madrid, to attend the queen of Spain, in three successive pregnancies, the last in the year 1720. About the year 1684, he was honoured by his sovereign and patron with letters of noblesse, with the condition attached to them, that he should continue to practise midwifery as long as his health and age should permit. He died on the 7th of October, 1729, being 80 years of age. Essais Historiques sur l'Art des Accouchmens, par M. Sue le jeune.

Clements' *strait*, in *Geography*, a branch of the great strait, that lies between Banca and Billiton in the East Indian ocean, being the "East Passage," between Middle or Passage island and Billiton. It is so called from captain Clements, the commander of a fleet of Indiamen, who is the first known navigator who attempted this passage in 1781, and struck out this new track to the ships of his own nation. The name of "Clements' Strait" distinguishes it from the "West Passage," or "Gaspar's Strait." See Banca.

Clements' Danes, St. a parish in the liberties of Westminster and county of Middlesex, which adjoins to the city of London: the situation of its church steeple, in the Strand, was determined in the government "Trigonometrical Survey," in 1788, by an observation from Argyle Street observatory, distant 6,074 feet; and another from Primrose-hill station, distant 14,391 feet: whence is deduced its bearing from the cross on the dome of St. Paul's cathedral 85° 57′ 37″ W. of the south meridian, and distance 3,592 feet. This steeple contains a singular clock with four dials, which strikes the hours, first on one of the great bells, and then repeats the same on a smaller bell; it repeats the quarters, and chimes the old hundredth psalm at 12, 5, and 9 o'clock.

CLEMENTE, Prospero, in *Biography*, a Modenese sculptor, who, according to Vasari, possessed considerable talents. In the Duomo of Reggio is a monument of white marble by this master, erected to the memory of bishop Rangone, who is represented in a sitting posture as large as life, with the accompaniment of two little angels beautifully executed. There is another monument by him at the Duomo of Parma, raised in 1548 to the memory of Bernardo degli Uberli of Florence, who was a cardinal, and bishop of Parma. Vasari ediz. di Bologna, tom. iii. p. 11. Orlandi.

Clemente, San, Don Bartolomeo di. See Lella Gatta.

CLEMENTI, in *Geography*, a town of European Turkey,

Turkey, in the province of Albania; 44 miles N. of Dulcigno.

CLEMENTINA, or CLEMENTINE HOMILIES, in *Ecclesiastical History*, are 19 homilies in Greek, published by Cotelerius, with two letters prefixed; one of them written in the name of Peter, the other in the name of Clement, to James bishop of Jerusalem; in which last letter they are entitled "Clement's Epitome of the Preaching and Travels of Peter." But it may be questioned, says Dr. Lardner, whether one or both of these letters do not belong to the "Recognitions." Photius seems to favour this supposition; at least, in his time, they were both prefixed to some editions of the "Recognitions." The 19th Homily is imperfect at the end; and there is wanting another whole homily to complete the number of twenty. Le Clerc thinks these Clementine Homilies were composed by an Ebionite in the second century. Montfaucon supposes that they were forged at a much later period, and that they were not mentioned by any author, till long after the age of St. Athanasius. This is one of his arguments, *viz.* that the Synopsis, in which the Clementines are mentioned, was not composed by that father. Grabe says, that the Clementines spoken of in that Synopsis, are not the same with our Clementine Homilies, which is very probable;—those Clementines mentioned in the Synopsis not being the Clementine Homilies, but the Clementine Epitome, published by Cotelerius at the end of the Homilies. Although these Clementine Homilies are ancient, they were not cited by the name of Clementines; but were reckoned either another edition of the Recognitions, or called the "Travels of Peter," or the "Disputation of Peter and Appion." There is a great agreement between these Homilies and the Recognitions, in several particulars. Dr. Lardner inclines to the opinion, that the Clementine Homilies were the original or first edition, and the Recognitions an improvement of them, because they appear more finished and artificial. This work is not improbably the same with that censured by Eusebius under the title of "Dialogues of Peter and Appion." The whole work is prolix; and in the 4th, 5th, and 6th Homilies is a history of Appion, and of a dispute with him. If this be the work of an Ebionite, as is generally supposed, and seems not improbable, it may be argued, that when the author wrote, the four gospels were owned by that sect, or at least by some branch of it; for though there may be some interpolations in these Homilies, there is no reason to think that any texts have been added. Although neither of these books, *viz.* the Homilies and Recognitions, be of any sacred authority, they may both be of some use; and deserve to be particularly examined. From what has been said it is probable, that the Clementine Homilies, and also the book of Recognitions, which Mr Whiston has recommended to us "as certainly to be esteemed in the next degree to that of the really sacred books of the New Testament," are the work of an Ebionite; and therefore if there is in it (says Dr. Lardner) any Arianism, it has been interpolated. As to the "Clementine Epitome," already mentioned, it seems to be the work of a later age; and to have been composed out of the Recognitions and Homilies, and perhaps some other works, leaving out some things, and adding others. To this Clementine Epitome, or some similar piece, the author of the Synopsis, ascribed to Athanasius, refers, when, among the contradicted or apocryphal books of the New Testament, such as the Travels of St. Peter, the Gospel according to St. Thomas, and some others, he mentions the "Clementines," "out of which," he says, "those things have been selected which are true and divinely inspired." This is probably the book of which Nicephorus speaks, as being in his time approved by the church. But in the composition of it, not only those things were selected which are true and right in the ancient Clementines, but several other things were added. The hand of an Ebionite in the Clementine Homilies is generally acknowledged by learned moderns. But that there was no good foundation, in the most early antiquity, for supposing St. Clement to be the author of any of those pieces, may be concluded from Eusebius. Moreover, it is notorious that the Clementine Epitome was composed by an orthodox christian. But it may be said in favour of the Catholics, that none of them appear to have had any hand in any of these Clementines during the first three centuries. It may be also added, that it was known the Clementine Epitome was not an original piece; and that it was not pretended to be really written by Clement, but was allowed to consist of things selected out of some other work or works. Lardner's works, vol. ii.

CLEMENTINE, a term used among the Augustins, who apply it to a person, who, after having been nine years a superior, ceases to be so, and becomes a private monk, under the command of a superior.

The word has its rise hence, that pope Clement, by a bull, prohibited any superior among the Augustins from continuing above nine years in his office.

CLEMENTINES, the name of a party which took its rise in Europe in the 14th century on the following occasion. After the pope had resided many years at Avignon, Gregory XI. was persuaded to return to Rome; and upon his death, which happened in 1380, the Romans, resolute to fix, for the future, the seat of the papacy in Italy, besieged the cardinals in the conclave, and compelled them, though they were mostly Frenchmen, to elect Urban VI., an Italian, into that high dignity. The French cardinals, as soon as they recovered their liberty, fled from Rome, and protesting against the forced election, chose Robert, son of the count of Geneva, who took the name of Clement VII. and resided at Avignon. All the kingdoms of Christendom, according to their several interests and inclinations, were divided between these two pontiffs. The court of France adhered to Clement, and was followed by its allies, the king of Castile, and the king of Scotland: England, of course, was thrown into the other party, and declared for Urban. Thus the appellations of "Clementines" and "Urbanists" distracted Europe for several years; and each party damned the other as Schismatics, and as rebels to the true vicar of Christ. This circumstance contributed in some degree to weaken the papal authority; but had not so great an effect as might naturally be imagined. Though any king could easily at first make his kingdom embrace the party of one pope or the other, or even keep it some time in suspence between them, he could not so easily transfer his obedience at pleasure. The people attached themselves to their own party, as to a religious opinion, and conceived an extreme abhorrence to those of the opposite party, whom they regarded as little better than Saracens or infidels. Crusades were even undertaken in this quarrel; and the zealous bishop of Norwich in particular led over, in 1382, near 60,000 bigots into Flanders, against the Clementines; but, after losing a great part of his followers, he returned with disgrace into England.

CLEMENTINES, in the *Canon Law*, are the constitutions of pope Clement V. and the canons of the council of Vienne. See CANON *law*, and CLEMENT V.

CLEMENTINES, in *Geography*, a tribe of Hungarians, so called from their leader, who emigrated in 1463, from Albania, baria, and arrived in 1737, through Servia at Sclavonia. They are dispersed in two villages.

CLEMENTINUS, Clement, in *Biography*, a learned physician of Amelia, near Spoleto in Italy, was in great credit towards the end of the 13th and the beginning of the 14th centuries. He was one of the restorers of medicine, and was well versed in the works of Hippocrates, and the rest of the fathers in that science. He taught philosophy and mathematics for some years at Padua, and appears to have imbibed the principles of astrology, with which his medical works are tinged. From Padua he was called to Rome, where he was appointed physician to Pope Leo X. whom he outlived only a short time. The work by which he is known is intitled, "Clementia Medicinæ, sive de Præceptis Medicinæ, et de Arte Medica, Romæ 1512, fol." Astruc says there was an earlier edition of this work, *viz.* in 1505. It was reprinted in 1535. He treats of temperaments and humours, of the pulse and urine, as indicating disease; of fevers, the plague, &c. He supposed the lues venerea, which made its first appearance in his time, was occasioned by the predominance of the constellation Scorpio. Haller. Bib. Med. Eloy. Dict. Hist.

CLEMONT, in *Geography*, a town of France, in the department of the Loiret, 9 leagues S.W. of Gieno. See also Clermont.

CLENCH-*nails*. See Nails.

CLENCHING, in *Sea Language*, denotes making fast the point of a bolt or nail, on a ring or rove of iron, by battering the point and making it spread. The cable is fastened or clenched to the ring of the anchor.

CLENZE, Lower, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Luneburg-Zell; 8 miles S.W. of Luckow.

CLEOBULUS, in *Biography*, one of the seven wise men of Greece, or, as some have called him, tyrant of Rhodes, was born at Lindus, in the isle of Rhodes, or, as some will have it, in Caria. He invited Solon to come and live with him, when Pisistratus had usurped the sovereignty of Athens. He flourished in the 54th Olympiad, about 564 years B.C.

CLEOBURY Mortimer, or Cleebury, in *Geography*, a small market-town of Shropshire, England, is situated at the base of a mountain, called the Clee-hills. These abound with iron-ore, lime, and coal, the latter of which is found in a vein 5 feet thick. The church is a large, handsome building; and near it is the site of an ancient castle, which was built by Hugh de Mortimer, and destroyed in the time of Henry II. Here is a free school, founded by sir Lacon William Child.

On Cleebury hill is an ancient encampment, another at Titterstone Clee, and another on the Urchin.

Here are a small weekly market on Thursday, and three annual fairs. Cleobury is 137 miles N.W. from London, and about 17 S. of Shrewsbury. Camden's Britannia, vol. ii. 1789.

CLEOFANTE, in *Biography*, an ancient painter, a native of Corinth, where he is said, by Pliny, to have first attempted to imitate in his figures the colour of the flesh, by means of bricks pounded. He flourished before the 40th Olympiad, and accompanied Demeratus, the father of Tarquinius Priscus, to Rome; when flying from the anger of Cipselus, prince of Corinth, he took refuge in Italy.

There existed at Lanuvio, in the time of Pliny, a picture of Atalanta, and another of Helen, by this master, both of which were well drawn. Winkelman. Orlandi.

CLEOME, in *Botany*, (from Κλειω, *claudo*, a name adopted by Linnæus, from Theod. Priscianus, called also Octavius, or Octavianus Priscianus, a medical writer of the fourth century). Linn. Gen. 826. Schreb. 1099. Willd. 1249. Gært. 479. Juss. 243. Vent. 3. 118. (Sinapistrum, Tourn. 116.) Class and order, *tetradynamia siliquosa*. Nat. Ord. uncertain, Linn. Philos. Botan. *Putamineæ*, Linn. Prælec. *Capparides*, Juss. Vent.

Gen. Ch. *Cal.* Perianth four-leaved, very small, spreading, the lower leaf more open than the others, caducous. *Cor.* Petals generally four, ascending and spreading, two intermediate ones smaller, and nearer together. *Stam.* Filaments varying in number, in different species, from six to more than twenty; awl-shaped, declining; in some species placed near the petals, on the common receptacle; in others attached to a pedicel which supports the germ; anthers lateral, ascending. *Pist.* Germ either sessile, or supported by a pedicel, differing very much in length in different species, generally surrounded by three nectariferous glands, one under each of three upper calyx leaves; style, in most species, none; stigma capitate. *Peric.* Silique pedicelled, or nearly sessile, oblong, cylindrical, one-celled, two-valved. *Seeds* numerous, kidney-shaped; attached to the inner side of a filiform, circular, or elliptic receptacle placed between the valves.

Ess. Ch. Three nectariferous glands; one under each division of the valves. Petals all ascending. Silique one-celled, two-valved.

This is a very anomalous genus, and imperfectly accords with the other genera of the Linnæan class tetradynamia, which form a completely natural family. Tournefort had before classed it among his plants with cruciform flowers, under the generic name of sinapistrum; but had placed it with chelidonium and epimedium, as having, like them, a one-celled capsule or silique. Linnæus, though he could not find a better station for it than at the tail of his class, tetradynamia, did not venture to pronounce it of the same natural family. In the "Philosophia Botanica," it appears among the vagæ, or plantæ incertæ sedis; in the "Prælections," published after his death by Gisecke, it stands in the natural order of putamineæ, which corresponds with the capparides of Jussieu and Ventenat. A few of the species at present admitted into the genus, are equally at variance with the essential character, nor is it, perhaps, possible to form one, which will include all of them. In the general character, we have thought it expedient to make considerable alterations.

Species. 1. C. *juncea*, Linn. jun. Supp. 300. Mart. 5. Poiret. 22. Willd. 1. Sparm. in Act. Upsal. Nov. vol. iii. p. 192. "Stem shrubby, leafless; flowers in lateral corymbs, eight-stamened, gynandrous; stamens and pedicel elongated; silique linear, tomentous." *Stem* from one to two feet high, scarcely the thickness of a goose-quill. *Branches* rigid, like spines, generally acute, greenish, cylindrical, spreading, smoothish. *Leaves* none; but, instead of them, minute scales, coming out here and there on the stem and branches. *Flowers* dirty yellow; common peduncle very short; partial ones from half an inch to an inch long, filiform, somewhat woolly, yellowish. *Calyx-leaves* rather spreading, somewhat orbicular, concave; two outer ones a little larger than the others, smooth within, somewhat rough, with crowded glands on the outside, and edged with others which are supported by pedicels; corolla none. *Nectary* short, tubular, two-lipped, fastened by the side to the base of the pedicel; upper lip very short, somewhat helmet-shaped, sometimes entire, sometimes toothed; lower lip more prominent, ascending, either sharpish and entire, or truncate-toothed; tube with a depression or channel on the outside, and at the top; pedicel lengthened out to an inch and half, the whole tubular, a third of its upper part staminiferous; stigma oblong. *Seeds* blackish, orbicular, some-

what

what compreſſed, and each, as it were, in its proper cell. Sparm. A native of the Cape of Good Hope, found near the Black river by Dr. Sparman. 2. C. *heptaphylla*, Linn. Sp. Pl. 2. Mart. 2. Poir. 1. Willd 2. (Sinapiſtrum, Tourn. Burm. Zeyl. 215. 3. Herm. Lugd. 564. Sloan. Jam. 1. 194. 4. Pentaphyllum, Moris. hiſt. 2. 288. 2.) "Flowers gynandrous; leaves with about ſeven leaflets; ſtem prickly." *Root* annual. *Stem* from three to five feet high, herbaceous, upright, angularly grooved, branched; branches ſpreading, grooved, viſcid, villous. *Leaves* alternate, ſcattered, ſpreading, digitate; common petioles erect, cylindrical, ſtreaked, hirſute, viſcid: leaflets lanceolate, acuminate, nerved, pubeſcent, ſpringing from a centre at their baſe; prickles in pairs at the baſe of the petioles, oppoſite, thick, ſhort, yellow, very pungent. *Flowers* white, or fleſh-coloured, in long looſe terminal ſpikes; peduncles two inches long, pubeſcent, cylindrical; bracte, one at the baſe of each peduncle, and half ſurrounding it, heart or almoſt creſcent-ſhaped, ſeſſile, entire, pubeſcent, white; calyx-leaves linear-lanceolate, acute, ſpreading, convex, pubeſcent; two of them a little longer than the others; petals with claws, oblong, concave, entire; filaments ſix, longer than the corolla, patulous, attached to the pedicel of the germ, red-purple; anthers long, erect, linear, brown; germ linear, quadrangular, green; ſtigma obtuſe, black. *Silique* five inches long, thick, tapering, pendulous. A native of Jamaica, whence it was ſent to Miller by Dr. Houſton. It is ſuppoſed to be a native alſo of Egypt and the Eaſt Indies. 3. C. *pentaphylla*, Linn. Sp. Pl. 3. Mart. 3. Poir. 2. Willd. 3. Jacq. Hort. tab. 24. Lam. Ill. tab. 576. fig. 1. Loureiro Cochin. 482. (Laganſa rubra, Rumph. Amb. tab. 96. fig. 2. Sinapiſtrum, Herm. Lugd. 564. Sloan. Jam. 80. Hiſt. 1. 294. Rai. Hiſt. 899. Papaver, Pluk. Alm. 280. Quinquefolium lupini folio, Bauh. Pin. 326. Capa-veela, Rheed. Mal. 9. tab. 24.) "Flowers gynandrous; leaves quinate; ſtem without prickles." *Root* annual. *Stem* about two feet high, herbaceous, upright; branches ſpreading, villous. *Leaves* on long, ſlender, villous petioles; leaflets roundiſh, acute, finely ſerrated, on ſhort petioles; floral leaves ternate, inverſely egg-ſhaped, obtuſe. quite entire; the loweſt on ſhort petioles, the reſt ſeſſile. *Flowers* white or fleſh-coloured, in a long terminal raceme or ſpike; peduncles axillary, ſolitary, one-flowered, ſpreading; calyx-leaves lanceolate; petals rounded, open, with long filiform claws; ſtamens ſix, attached to the pedicel of the germ about the middle, equal, ſpreading; pedicel of the germ long, ſlender, purple. *Siliques* three inches long, rough with rigid, blunt, very ſhort hairs, wrinkled or dotted. *Seeds* kidney-ſhaped, in ſix rows. We have blended the deſcription of Jacquin and Loureiro, as there ſeems no doubt with reſpect to the identity of their reſpective plants. A native of the Eaſt and Weſt Indies, Cochinchina, Guinea, and Syria. 4. C. *triphylla*, Linn. Sp. Pl. 2. Mart. 4. Poir. 3. Willd. 4. (Sinapiſtrum, Herm. Lugd. tab. 565.). "Flowers gynandrous; leaves ternate; ſtem without prickles." *Root* annual. *Stem* about two feet high, herbaceous, upright, almoſt ſmooth, branched. *Leaves* on long petioles; leaflets almoſt ſeſſile, oval, lanceolate; the middle one larger than the two others. *Flowers* fleſh-coloured, in a ſhort terminal ſpike; peduncles long, ſolitary; floral leaves lanceolate, acute, terminated by a ſhort point, ſlightly ciliated at their edges: filaments ſhort, ſtraight; ſtigma flattened. *Siliques* four inches long, oblong, obtuſe at the ſummit. A native of the Eaſt and Weſt Indies. *Obſ.* Linnæus, judging from a ſimilarity of habit, and a conformity in ſeveral ſtriking characters, was inclined to think that the laſt three are rather varieties than diſtinct ſpecies. He alſo calls them gynandrous, conſidering the pedicel of the germ as a proper ſtyle, and founding his opinion, we preſume, on the analogy of paſſiflora; but we cannot think that either one or the other has a right to be termed gynandrous. The pedicel does not appear to us to perform the office of a ſtyle in [illegible] reſpect whatever, any more than that which ſupp[illegible] germ in the genus euphorbia. 5. C. *pungens*, Willd. [illegible] Berol. Annals of Botany. 1. 567. "Leaves quinate; ſtem prickly." *Leaves* viſcid. *Flowers* fleſh-coloured. A native of South America. 6. C. *polygama*, Linn. Sp. Pl. 8. Mart. 6. Poir. 4. Willd. 5. (Sinapiſtrum, Sloan. Jam. 80. Hiſt. 1. tab. 124. fig. 1). "Upper flowers maſculine, tetrandrous; leaves ternate; leaflets ſeſſile, ſomewhat prickly at the edges." *Stem* not above twenty or twenty-five inches high, a little branched, erect, almoſt ſmooth. *Leaves* on long petioles; leaflets ovate-lanceolate, a little rough at their edges. *Flowers* in a long raceme; the loweſt fertile; the reſt minute, male germ ſeſſile within the calyx. A native of Jamaica, in moiſt bottoms. 7. C. *icoſandra*, Linn. Sp. Pl. 5. Mart. 9. Poir. 5. Willd. 6. Lour. Cochin. 483. (Sinapiſtrum, Burm. Zeyl. tab. 99. Laganſa alba, Rumph. Amb. tab. 96. fig. 3.) "Flowers icoſi-tetrandrous; leaves quinate." *Root* annual. *Stem* two feet high, herbaceous, erect, ſtriated, viſcid-villous, without prickles; branches aſcending. *Leaflets* ovate-lanceolate, ſeſſile, quite entire, a little rough. *Flowers* yellowiſh, in ſolitary axillary ſpikes along the branches; calyx campanulate; leaves four, lanceolate, caducous; petals twice the length of the calyx, ſpreading, ovate-oblong, almoſt equal; ſtamens from eighteen to twenty-two; filaments ſhort, awl-ſhaped, equal, placed on a flattiſh receptacle; anthers awl-ſhaped, recurved; germ ſeſſile, oblong, terminated by a ſhort ſtyle and obtuſe ſtigma. *Silique* long, awl-ſhaped, obliquely ſtriated, without nectariferous glands at its baſe. *Seeds* kidney-ſhaped. A native of cultivated ground in China and Cochinchina. The whole plant, except the petals and ſtamens, is cloathed with viſcid hairs. It has an acrid, hottiſh taſte, ſimilar to that of muſtard, and is eaten by the natives in ſallads mixed with other herbs. 8. C. *viſcoſa*, Linn. Sp. Pl. 6. Mart. 10. Poir 6. Willd. 7. (Sinapiſtrum, Mart. Cent. tab. 25. Aria-veela, Rheed. Mal. 9. tab. 23?) "Flowers dodecandrous; leaves quinate and ternate." *Root* annual. *Stem* two or three feet high, upright, ſtiff, almoſt woody, angular, cloathed with viſcid hairs, branched. *Leaves* alternate, on long petioles; leaflets oval, ſomewhat rhomboid, ſlightly petioled. *Flowers* yellow, ſmaller than thoſe of the preceding ſpecies, axillary and ſolitary along the branches, with a terminal raceme; calyx-leaves erect at the bottom, ſpreading a little at the top, all expanding regularly, lanceolate, equal; petals lanceolate-ovate; two lower ones more divaricated than the others; ſtamens from eight or nine to thirteen, placed on the receptacle, unequal; germ ſeſſile. *Silique* about two inches long, very villous, viſcid, ſlender, longitudinally ſtriated, terminated by a ſtigma on a ſhort ſtyle. A native of Malabar and the iſland of Ceylon. 9. C. *dodecandria*, Linn. 7. Mart. 11. Poir. 7. Willd. 8. (Sinapiſtrum, Burm. Zeyl. 216. tab. 100. fig. 1.) "Flowers dodecandrous; leaves ternate." *Root* annual, long. *Stem* about half a foot high; ſometimes erect, ſimple; ſometimes almoſt creeping, with decumbent branches, ſlightly villous, ſomewhat viſcid. *Leaves* ſmall, petioled; leaflets ſmooth, elliptical, quite entire, ſeſſile. *Flowers* white, axillary, ſolitary; upper ones abortive; calyx nearly as long as the corolla, purple; petals emarginate; ſtamens from ten to fourteen, placed on the receptacle. *Siliques* ſeſſile, ſmooth, compreſſed, erect, almoſt tranſparent, ſpindle-ſhaped, a little inflated. *Seeds* very ſmall, ſmooth, ſhining, brown, convex on one ſide, concave on the other, nearly kidney-ſhaped. A native of the Eaſt Indies. There is a plant cultivated in the botanic garden at Paris, under the name of C. canadenſis, which greatly reſembles this ſpecies. It is, however, larger in all its parts, and more branched; its ſiliques are alſo villous, at leaſt when young, and all its flowers fertile. It has an unpleaſant bituminous ſmell. In other reſpects it agrees with C. dodecandria. 10. C. *felina*, Linn. jun. Supp. 300. Mart. 8. Poir. 20. Willd. 10. "Polyandrous, hiſpid; leaves ternate, ſtrigoſe, wedge-ſhaped; flowers axillary, ſolitary, peduncled; ſiliques linear, compreſſed." *Leaves* ſomewhat retuſe. *Flowers* red, ſmall, angular. *Siliques* ſhort, ſmooth. This diminutive plant is ſingular in its hiſpid leaves; the hairs much dilated at the baſe, very ſtiff, preſſed cloſe to the leaves, and pointing towards their extremity, ſo as to give it ſomewhat of the roughneſs of a cat's tongue. Found in Ceylon, by Koenig. 11. C. *chelidonii*, Linn. jun. Supp. 300. Mart. 7. Poir. 20. Willd. 10. "Polyandrous, hirſute; leaflets five or ſeven, wedge-ſhaped, ſcabrous; racemes terminal; ſiliques filiform." *Leaves* on long petioles, digitate; leaflets acute. *Flowers* red, reſembling thoſe of chelidonium hybridum; calyx three or five-leaved, ſtrigoſe; petals five; ſtamens yellow. *Silique* quite ſmooth. It has clearly a great affinity to chelidonium. Poiret obſerves, that a more accurate inveſtigation is neceſſary before its real genus can be determined. A native of the Eaſt Indies, found by Koenig near Tanſchaur. 12. C. *gigantea*, Linn. Mant. 430. Mart. 12. Poir. 8. Willd. 11. Jacq. Obſ. 4. p. 1. tab. 76. "Flowers hexandrous; leaflets in ſevens; ſtem without prickles." *Root* perennial. *Stem* from ſix to twelve feet high, erect, pubeſcent, always green; branches ſimple, diffuſe, ſcarred. *Leaves* alternate, petioled; petioles longer than the leaves; leaflets quite entire, lanceolate, pubeſcent, ſilky on the upper ſurface, acute, ſeſſile. *Flowers* greeniſh; raceme terminal, erect, near two feet long; peduncles glutinous, longer than the flowers, without bractes; calyx-leaves linear, ciliated, ſpreading, caducous; petals oblong, obtuſe, undulated, cloſely cohering, except in front, where the ſtamens appear; claws diſtinct, the length of the petals; filaments inclining, longer than the petals, attached to the receptacle; anthers erect, oblong, yellow; germ pedicelled; pedicel the length of the ſtamens; ſtigma ſeſſile, obtuſe; receptacle globular, exuding a ſweet liquor at the baſe of the claws. It is a beautiful plant, but has a ſtrong diſagreeable ſmell, and very cauſtic taſte. A native of Cayenne: introduced into England by Dr. Fothergil in 1774. 13. C. *aculeata*, Linn. Syſt. Nat. iii. p. 232. Mart. 13. Poir. 9. Willd. 12. "Flowers hexandrous; leaves ternate, quite entire; ſtipules ſpineſcent; ſiliques ſeſſile." *Stem* herbaceous. *Leaves* elliptic-lanceolate, on long petioles; leaflets lanceolate, acute, ſomewhat ciliated and thorny at the edges, almoſt ſmooth, on very ſhort petioles; ſtipules two, very ſhort, recurved, citron-coloured, pale yellow, ſmall, ſolitary, peduncled; bractes at the baſe of the peduncles, ſimple; calyx-leaves acute, lanceolate, tomentous, whitiſh, caducous; claws of the petals long, almoſt filiform; ſtamens ſhorter than the corolla, placed on the receptacle; germ ſeſſile. *Silique* cylindrical, beſet with fine white hairs. Obſerved in America by Zoega. 14. C. *ſpinoſa*. Linn. Sp. Pl. 9. Mart. 14. Poir. 10. Willd. 13. Jacq. Amer. 190. 3. Pict. 93. Swartz. Obſ. 252. Brown Jam. 273. n. i. (Tarieraga, Marcgr. Braſ. 33. tab. 34.) "Flowers hexandrous; leaflets ſeven or five; ſtem thorny; ſiliques peduncled." *Root* annual. *Stems* five or ſix feet high, erect, villous, branched. *Leaves* alternate, on long petioles; leaflets entire, lanceolate, nerved, almoſt wrinkled, ſlightly viſcid-pubeſcent, edged with ſhort hairs, only three towards the extremity of the branches; ſpines two at the baſe of each petiole, oppoſite, ſhort, recurved, acute, yellowiſh. *Flowers* white, in a long terminal raceme; peduncles ſolitary, one-flowered; bractes ſhorter than the peduncles; heart-ſhaped, ſeſſile, obtuſe, approximating, nerved, pubeſcent; calyx-leaves linear-lanceolate, acute, ſpreading, concave, as long as the claws of the petals; petals oblong, entire, with elongated claws, and a roundiſh gland at the baſe of each; ſtamens unequally placed on the receptacle; filaments nearly equal, ſpreading, filiform, longer than the corolla, purple; anthers erect, long, two-celled, yellow; pedicel of the germ filiform, twice the length of the corolla. *Silique* three or four inches long, cylindrical, toruloſe, pubeſcent, viſcid, terminated by the obtuſe ſtigma. *Seeds* numerous, oblong. A native of the Weſt Indies. Sent from the Havannah to Miller by Dr. Houſton in 1731. 15. C. *ſerrata*, Linn. Sp. Pl. 10. Mart. 15. Poir. 11. Willd. 14. Jacq. Amer. tab. 190. fig. 43. "Flowers hexandrous; leaves ternate; leaflets linear-lanceolate, ſerrated." *Root* annual. *Stem* two feet high, erect; branches looſe, ſimple. *Leaves* petioled; leaflets almoſt equal; the middle one on a ſhort petiole. *Flowers* white; ſtamens tetradynamous. *Silique* about three inches long, cylindrical. A native of moiſt woods in South America, about Carthagena. 16. C. *ornithopoides*, Linn. Sp. Pl. 12. Mart. 16. Poir. 12. Willd. 15. (Sinapiſtrum, Tourn. Cor. p. 17. Dill. Elth. tab. 266. fig. 345. Buxb. Cent. i. tab. 9. fig. 2.) "Flowers hexandrous; leaves ternate; leaflets oval-lanceolate." *Root* annual. *Stem* about two feet high, pale green, cloathed with ſhort, ſtiffiſh hairs. *Leaves* ſtrong-ſcented, on rough petioles; leaflets of a pale glaucous colour on both ſides, commonly bent back, ſmooth in appearance, but roughiſh to the touch, edged with numerous ſhort hairs, on very ſhort peduncles. *Flowers* pale yellow, ſmall, axillary; calyx-leaves very ſmall, ovate, concave; ſtamens placed on the receptacle, inclining, ſcarcely longer than the petals; anthers ſmall, ſaffron-coloured; germ ſeſſile. *Siliques* two inches long, ſlender, a little hirſute, appearing jointed when ripe, like the legume of ornithopus. Obſerved in the Levant by Tournefort, and at Peru by Buxbaum. Cultivated in England by Dr. James Sherard in 1732. 17. C. *violacea*, Linn. Sp. Pl. 13. Mart. 17. Poir. 13. Willd. 16. Gært. tab. 76. fig. 6. Lam. Ill. tab. 567. fig. 3. "Flowers hexandrous; leaves ternate and ſimple; leaflets lanceolate-linear, quite entire. *Root* annual. *Stem* erect, ſometimes crooked; branches diffuſe. *Leaves* on long petioles; leaflets nearly equal, obtuſe, ciliated at their edges. *Flowers* violet-coloured, ſolitary, in a looſe ſpike; calyx-leaves yellow, with purpliſh tips, ſhort, ovate, concave; the two upper petals purple-violet, with ſmall yellow ſpots; the two others of an uniform colour, heart-ſhaped, clawed, ſlightly crenulate, ſtamens inclining, attached to the receptacle; anthers violet; germ ſeſſile, longer than the ſtamens; receptacle furniſhed, above the inſertion of the ſtamens, with three yellowiſh glands, Poir. *Peric.* a ſiliquoſe capſule on a very ſhort pedicel, oblong, obtuſe, compreſſed, villous. *Seeds* twelve or more, ſomewhat globular, with a ſmall pit on each ſide, acuminate towards the navel, ſmooth, of a ruſty red colour, Gært. The whole plant is pubeſcent and viſcid. A native of Spain and Portugal. 18. C. *arabica*, Linn. Sp. Pl. 11. Mart. 18. Poir. 14. Willd. 17. Linn. Decad. iii. tab. 8. (Sinapiſtrum, Shaw. Afr. fig. 557.) "Flowers hexandrous; leaves ternate; leaflets lanceolate, obtuſe; ſeeds hirſute." *Root* annual. *Stem* about two feet high, herbaceous, viſcid, rough with hairs; branches diffuſe. *Leaves* alternate petioled; petioles as long as the leaves, hiſpid,

hispid, viscid; leaflets sessile, scabrous underneath, lanceolate, obtuse, finely toothed. *Flowers* yellow, tinged with purple at the summit, twice as large as the calyx; stamens inclining, a little longer than the corolla, placed on the receptacle; germ sessile. *Silique* almost transparent, a little curved at the summit, somewhat inflated, obtuse, short; peduncle inclining. *Seeds* globular, kidney-shaped, very hispid, with erect whitish hairs. A native of Arabia. 19. C. *tenella*, Linn. jun. Supp. 300. Mart. 22. Poir. 22. Willd. 18. Retz. Obs. 4. 28. n. 91. "Flowers hexandrous; leaves ternate; leaflets filiform, linear." *Root* annual. *Stem* about seven inches high, upright, branched. *Leaflets* sessile, the length of the petals. *Siliques* linear, Linn. jun. *Flowers* yellow, on solitary peduncles, Retz. A native of the East Indies. 20. C. *angustifolia*, Poir. 19. Forskal. Flor. Arab. p. 120. (C. filifolia, Mart. 23. Willd. 19.) "Leaflets in sevens and threes, filiform." *Root* annual. *Stem* a foot high or more, cylindrical branched, Forsk. *Stem* erect, weak, herbaceous, striated; dotted towards the summit, with elevated minute, scattered points, Vahl. *Leaves* alternate, digitate; petiole two inches long; leaflets seven, flat, linear, smooth, rather thick; three linear ones at the base of the peduncles, sustaining the office of bractes, Forsk. *Leaves* petioled; petioles shorter than the leaves; lower leaflets in sevens, upper ones ternate, Vahl. *Flowers* yellow, with a violet base in terminal racemes; peduncles half an inch long, straight, spreading, cylindrical, solitary, one-flowered; calyx-leaves equal; petals all united in their upper part; outer ones larger, nearly oval; the two inner ones only half the length of the others, oblong, linear; stamens six; filaments violet-coloured, diminishing in size by pairs; the two lower pairs taper at the summit, with black and yellow erect anthers; the stamens of the upper pair yellow, barren, with a club-shaped summit; rudiment of the anther globular, yellow, small, sessile at the top of the filament. *Silique* two inches long, at first erect, afterwards pendulous. *Seeds* smooth, Forsk. *Silique* pedicelled, attenuated at the tip, Vahl. A native of Egypt and Arabia. 21. C. *guianensis*, Poir. 18. Willd. 20. Aubl. Guian. ii. p. 675. tab. 273. "Flowers hexandrous; leaves simple, linear-filiform, sessile." *Root* annual. *Stem* a foot high, branched from the bottom. *Leaves* green, alternate, very narrow, acute. *Flowers* yellow, axillary, solitary, on long slender peduncles; calyx-leaves small, long, acute; petals oval, ending in a point, leaning to one side; stamens inserted into the receptacle; filament yellow, slender, the length of the pistil; anthers arrow-shaped, attached to the filament by their middle; germ long, inflated, a little curved, green; separated from the petals, and leaning to the opposite side; stigma obtuse. *Silique* long, smooth, a little inflated. *Seeds* small, roundish. A native of Guiana, on the sea-coast. 22 C. *monophylla*, Linn. Sp. Pl. 14. Mart. 19. Poir. 15. Willd. 21. (Sinapistrum, Burm. Zey. tab. 100. fig. 2. —— tsjeru-vela, Rheed. Mal. 9. p. 63. tab. 34. —— papaver, Pluk. Alm. p. 280.) "Flowers hexandrous; leaves simple, ovate-lanceolate, petioled." *Root* annual. *Stem* a foot and half high, herbaceous, erect, striated, villous, branched near the top. *Leaves* alternate, long, narrow, entire, somewhat villous, viscid, ending in a point, finely toothed; petioles shorter than the leaves. *Flowers* yellow, solitary, peduncled at the extremity of the branches; calyx-leaves small, linear, villous; stamens placed on the receptacle, the length of the petals; anthers greenish-blue; germ sessile. *Silique* slender, cylindrical, somewhat villous, striated, ending in a point. A native of the East Indies. 23. C. *capensis*, Linn. Sp. Pl. 15. Mart. 24. Poir. 16. Willd. 22. (C. juncea, Berg. Plant. cap. 164?) "Flowers hexandrous; leaves simple, sessile, linear-lanceolate; stem angular." *Stem* simple, stiff and upright, resembling that of an epilobium. *Leaves* like those of the common broom, stiff, smooth. *Flowers* corymbed, as in epilobium. Linn. Bergius describes his plant thus: *Stem* more than a foot high, herbaceous, erect, cylindrical, striated, smooth; branches alternate, simple, long, upright. *Leaves* an inch long, alternate, smooth, obtuse, fleshy. *Flowers* yellow, tinged with purple, in thin racemes; peduncles alternate, one-flowered; calyx-leaves ovate, rather acute, small, equal, permanent; petals wedge-shaped, obtuse, erect, equal, several times longer than the calyx; claws yellowish, short, linear; filaments short, awl-shaped; germ sessile, almost heart-shaped, compressed; style very short, thickened, compressed, permanent; stigma obtuse. *Silique*, when young, heart-shaped, rough with strong points, two-celled, two-valved. *Seeds* orbicular, flat, one in each cell. Bergius did not see the fruit in a state of maturity. The real genus of the plant does not appear to have been satisfactorily ascertained. A native of the East Indies and the Cape of Good Hope. 24. C. *procumbens*, Linn. Sp. Pl. 16. Mart. 21. Poir. 17. Willd. 23. Jacq. Amer. 189. tab. 120. Swartz. Obs. p. 254. (Sinapis, Brown Jam. 273. 2. Leucoium, Sloan. Hist. 1. tab. 123.) "Flowers hexandrous; leaves simple, lanceolate, petioled; stems procumbent." *Root* perennial, spindle-shaped, striking deep into the earth. *Stem* almost woody, branched from the bottom; branches spreading on the ground, finally ascending and dividing into smaller ones, smooth. *Leaves* alternate, smooth, quite entire, acute. *Flowers* yellow, turning to orange or red, axillary, solitary; peduncles one-flowered, purple; calyx-leaves five, lanceolate, concave, acute, open, equal; petals oblong, expanding, twice the length of the calyx; stamens equal, the length of the petals; anthers blackish, ovate, revolute, two-celled; germ on a very short pedicel, acuminate, compressed; style awl-shaped; stigma obtuse. *Silique* pedicelled, erect, cylindrical, somewhat torulose. *Seeds* echinate, black. No nectariferous glands have been observed. A native of the West Indies.

Propagation and Culture. Most of the species being natives of very warm climates, will not thrive in England without artificial heat. They are raised from seeds sown in the spring, and require the same treatment as other tropical plants.

CLEOME *fruticosa*, Linn. See CADABA *indica*.

CLEOMENES, in *Biography*, the son of Apollodorus the Athenian, is engraved in the Greek characters on the base of the celebrated statue of the Venus de Medicis. The name is by many, however, supposed a spurious introduction of the fifteenth or sixteenth centuries. Carlo Dati. Orlandi.

CLEOMENES, the name of several kings of Lacedæmon. The most celebrated of these was the last or *Cleomenes* III. He ascended the Spartan throne on the death of his father Leonidas, in the 2d year of the 136th olympiad, 235 years B.C.; and in the commencement of his reign, though he was then very young, he found himself obliged to exert both his conduct and his courage. Aratus, at the head of the Achæans, had formed a project of uniting all the states of Peloponnesus in a league; and soon after the death of Leonidas, despising the youth of Cleomenes, he determined to try the disposition of the Spartans, who had not acceded to this league, and with this view he invaded the Arcadians, who were their neighbours and friends, and lived under their protection. When the Ephori heard of this aggression, they ordered Cleomenes to take the field, and to seize on a pass into Laconia, which was then in the hands of the allies

allies of the Achæans. Having performed this fervice, he afterwards difappointed Aratus in his defign of feizing Pegæa and Orchemanium. Upon the retreat of the Achæan general, the young king fent a taunting meffage to him; but the old ftatefman, deriding his youth, afked Democritus, a Spartan exile, who lived with him, "What fort of a perfon this Cleomenes was?" "Why, my friend," replied the Spartan, "I will anfwer you in few words; if you have any thing to do againft the Lacedæmonians, let me advife you to begin before this young eagle's talons are grown." Such was the difparity in number between the troops of Cleomenes, which amounted to no more than 5000, and thofe of the Achæans, confifting of 20,000 foot and 1000 horfe, that Cleomenes, having compelled the enemy to retreat, reminded his fellow-citizens of an expreffion ufed by one of their ancient kings, who faid, "That the Lacedæmonians never inquired after the number of their enemies, but where they were." In the courfe of the war, however, Aratus, by his great fkill, obtained fome advantages over the Spartans; but the reputation of Cleomenes for courage and military virtues was fuch, that the people of Sparta feemed to acquire a new fpirit from the martial prowefs of their fovereign. The Ephori, dreading the rifing fame and correfponding influence of Cleomenes, wifhed to put an end to the war: the king perceived their defign; and in order to counteract it, he determined to fupprefs the Ephori, and thus to fecure his own power, and at the fame time to reftore the glory of his country. For this purpofe he contrived, by money, to engage the Ephori in a war, and to give him the command of their army. Cleomenes, having fucceeded in this meafure, took with him into the field thofe perfons whom he had the greateft reafon to fufpect; and having performed feveral acts of valour, he marched his army with a rapidity which haraffed it, and induced many to be left behind in Arcadia; and with the reft he advanced flowly towards Lacedæmon. As he approached the place, he difpatched a fmall party, who, furprifing the Ephori at fupper, inftantly killed four of them, and would alfo have flain the fifth, if he had not feigned himfelf dead, and thus gained an opportunity of retiring to a temple, where he remained uninjured.

On the next morning Cleomenes went into the forum, and caufed all the feats of the Ephori to be removed, except one, which he referved for himfelf, and then artfully apologized to the people for his conduct. He perfuaded them, that it was neceffary to reftore the inftitutions of Lycurgus; and affured them, that notwithftanding the violence to which he had been obliged to recur for the accomplifhment of this purpofe, he was determined, for the future, to pay a ftrict regard to the laws, though the prefent occafion, and his perfonal fafety, required him to profcribe 80 citizens. He was the firft who delivered up his whole fubftance to the public ftock, and his example was followed by his father-in-law, and other friends. In affigning the lands, he gave fhares to all whom he had banifhed, promifing to recal them as foon as the public fafety would admit of it; and immediately after he reftored the old Laconic mode of educating youth, of eating in public, and performing their exercifes together; he alfo raifed a confiderable body of troops, and difciplined and armed them in a new manner. In order to manifeft his abhorrence of tyranny, and to prevent any offence from his purfuing thefe meafures by his own authority, he affociated his brother Euclides in the kingdom, declaring, that for the future, there fhould be always two kings in Sparta, according to ancient cuftom, and that he would not erect a monarchy, in order to tranfmit it to pofterity. Befides, in order further to ingratiate himfelf with the people, and to eftablifh his own popularity and power, he adopted a courfe of life, which was not in any refpect more expenfive than that of the meaneft citizen. In his houfe he had no purple furniture, no canopies, or cloths of ftate, no fuperb chairs, nor couches for indulging eafe, but every thing about him was diftinguifhed by its plainnefs and fimplicity. When any perfon offered petitions, he very readily received them; converfed freely with thofe that had eafy accefs to him; redreffed all injuries that were committed by others, and did no injury himfelf; and at the fame time his virtue was altogether free from affectation or aufterity. Having thus eftablifhed his intereft with the people, notwithftanding the alterations he had introduced, he marched with a body of troops into the territories of the Achæans, and gained feveral important advantages over Aratus. Neverthelefs he did not avail himfelf of his victories, in oppreffing any of the cities which he acquired, but reftored their liberty, and, when occafion offered, recalled their ancient inhabitants. The Achæans, difcouraged by his fucceffes, were difpofed to accede to any terms which he propofed; and Cleomenes, with a generofity that feldom attends very decifive conquefts, merely defired to be acknowledged general of the Greeks, ftipulating at the fame time, to deliver up his prifoners without ranfom, and to reftore the cities which he had taken. Lerna was appointed as the place of treaty, and the Achæans were willing to acquiefce; but in his way thither, Cleomenes fell into a fever, which rendered it neceffary for him to adjourn the meeting to another time and place. Aratus feized the advantage offered to him by this delay, and concerted meafures for preventing his advancement to the dignity after which he afpired, and to which his merit gave him a juft claim. After his recovery, he proceeded towards Argos, where the Achæans held their affembly; but, as he approached it, Aratus difpatched a meffenger to inform him, that he muft either enter the city alone, or be content to treat without the place. This meffage he confidered as an act of hoftility, and he foon after declared war. Encouraged by the difcontent and divifions that prevailed among the Achæans, he took Pellene by furprife, and expelled the Achæan garrifon; and, after taking poffeffion of other places, he furprifed Argos, and raifed himfelf to a greater degree of power than any of his predeceffors had poffeffed, and his city to a greater pre-eminence than fhe had ever held in Greece. He wifhed, however, to treat with Aratus, and to engage his friendfhip; but the Achæan general, having determined to deftroy the Spartan greatnefs, was invincible. In the courfe of the war, Cleomenes, with a force inferior to that of the enemy, who had called Antigonus to his affiftance, defended the far greater part of Peloponnefus, till Argos was betrayed; even then he exerted himfelf, and, when overpowered by numbers, made a moft glorious retreat. At this time he received from Sparta the intelligence of the death of his wife, to whom he was affectionately attached; but he bore the afflictive news with fortitude, and refumed the functions of a monarch and a general, without fuffering his private concerns to interfere with the conduct of public affairs. Ptolemy offered him his friendfhip; but impofed a condition which much affected him, and that was his fending his mother, Crateficlia, and his fon, as hoftages. Whilft he was unable to communicate this demand to his mother, and hefitating to explain himfelf, fhe laughingly faid, "Well, was it this which you were afraid of imparting? Why do you not put me on fhip-board, and fend this carcafe where it may be ferviceable to Sparta, before age has wafted it unprofitably here?" Before fhe embarked, fhe retired with her fon into the temple of Neptune, where, while he wept, fhe tenderly embraced him,

him, and faid, "Come, king of Sparta, let us dry our tears, that no figns of grief may appear when we go out, nor any token of weaknefs unworthy your dignity, or the honour of our country, fince our actions are all that are within our power, and events belong wholly to providence." Afterwards writing to Cleomenes from Egypt, fhe addreffed him in thefe words: "King of Sparta, do what is worthy of your country, and what may redound to its advantage; nor, for the fake of an old woman, and a little child, ftand in fear of what Ptolemy may do." In the profecution of the war, Cleomenes difplayed his conduct and valour; and though unequally matched againft the number and difcipline of his enemies, he kept the war out of Laconia, took the city of Megalopolis, which was larger than Sparta, in the midft of the armies of king Antigonus; and then generoufly offered to reftore it untouched to its citizens; but when they rejected his offer, he abandoned it to the plunder of his foldiers. He afterwards haraffed the territory of Argos, and, as the ftate of his army required fpeedy action, he provoked Antigonus to engage, whilft he had the advantage of the ground; however, this cautious and fkilful officer declined a conteft till a more proper opportunity offered. At length the two armies engaged at Sellafia, where Cleomenes was defeated with very great flaughter. After the termination of this difaftrous battle, he retired to Sparta; and, after fome deliberation, in which he manifefted diftreffing anxiety, he determined to retire to Egypt. In the execution of his purpofe, he embarked at Gythium, and paffed over to Ptolemy Euergetes, who entertained him honourably while he lived; but his fon, indulging fufpicion of him, deprived him of his liberty; an outrage which Cleomenes after fome time refented, fo that he, with 12 friends, forced the place where he was confined; but afterwards finding it impracticable to efcape, they flew each other. Thus died Cleomenes, in the firft year of the 140th Olympiad, 220 years B. C. after having reigned 16 years over Sparta. Ptolemy Philopater, actuated by a fpirit of brutal revenge, caufed his body to be hanged on a crofs, and ordered his mother, children, and all the women who attended them, to be put to death. When that unhappy princefs was brought to the place of execution, the only favour fhe afked was, that fhe might die before her children. But they began with them; a torment more grievous to the affectionate parent than death itfelf; after which fhe prefented her neck to the executioner, merely faying, "Ah! my dear children, to what a place did you come!" With Cleomenes ended the Herculean race of Spartan kings, if we except the fhort reign of Agefipolis, his fucceffor. Plut. in Cleom. apud opera T. i. p. 795. Polyb. lib. ii. Anc. Un. Hift. vol. v. Rollin's Anc. Hift. vol. v.

CLEON, an Athenian general, who rofe from obfcurity to the command of the armies of the ftate, by his intrigues and eloquence. He was rafh and obftinate, and was killed at Amphipolis, in a battle with Brafidas, the Spartan general, B.C. 422.—There was alfo a famous ftatuary of this name; alfo a poet, who wrote a poem on the Argonauts; alfo an orator of Halicarnaffus, who compofed an oration for Lyfander, in which he intimated the propriety of making the kingdom of Sparta elective; and a Magnefian, who wrote fome commentaries, in which he fpeaks of portentous events, &c.

CLEONÆ, in *Ancient Geography*, a maritime town of Macedonia, on a peninfula of Mount Athos, between Thyffus and Acro-Athos, according to Thucydides and Pliny. It was a colony of Chalcidians, according to Heraclides.—Alfo, the laft town of the Argolide on the fide of Corinth. In the time of Paufanias, it had a temple and ftatue of Minerva. Homer applied to it the epithet of Ευκτιμενας, which fuggefts the idea of a fine city.—Alfo, an ancient town of Greece, in the Phocide, near Hyampolis, according to Plutarch.—Alfo, an ancient town of Peloponnefus, in Arcadia, according to Pliny, who diftinguifhes it from that of Achaia.

CLEONEO, CIMONE, in *Biography*, a very ancient painter of Greece, who is faid to have firft attempted to give a variety to the actions of his figures, by making them look up or down, or fore-fhortening them as the fubject required; befides which he defcribed the joints and the veins of his figures better than any of his predeceffors, and imitated the folds of drapery with fome fuccefs. Borghini. Della Valle. Vite dei Pitt. Ant.

CLEONIA, in *Botany*, κλεωνυκιαν or κλεωνια, Theophraft. lib. 7. cap. 4. Diofc. lib. i. in Append. cap. 27. Cleonæum, Plin. lib. xix. cap. 5.) Linn. Gen. 736. Schreb. 991. Gært. 407. Clafs and order, *didynamia gymnofpermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juff.

Gen. Ch. *Cal.* perianth one-leafed, tubular, angular, two-lipped; upper lip flattifh, broad, three-toothed; lower lip two-parted, fhort. *Cor.* one-petalled, ringent; upper lip ftraight, bifid, keeled; lower lip trifid, middle fegment two-lobed; fide ones fpreading. *Stam.* Filaments four, forked at the end; the two lower longeft; anthers feated on the lateral branch of one of the filaments, croffed in pairs. *Pift.* Germ four-parted; ftyle filiform, the length of the ftamens; ftigmas four; fetaceous, equal; Linn. Four-cleft, Gært. *Peric.* none, except the permanent calyx clofed with hairs. *Seeds* four, nearly columnar, fmooth.

Eff. Ch. Filaments forked, with an anther at the end of each lateral branch; ftigma four-cleft.

Sp. C. *lufitanica*, Linn. Sp. Mart. Willd. Gært. tab. 66; fig. 7. Desf. Atl. 2. p. 32. (Brunella odorata, Lam. Juff. Vent. Prunella odorata lufitanica; Barr. Ic. 561. Clinopodium lufitanicum fpicatum et verticillatum, Tourn. Inft. 195.) *Root* annual. *Stem* fix or eight inches high, erect, very villous, a little branched towards the top. *Leaves* elongated, narrowed at the bafe, obtufe at the end, ftrongly toothed; upper ones pinnatifid; bractes deeply laciniated, narrow, acute, ciliated. *Flowers* violet-coloured or bluifh, large, in a terminal hifpid fpike; upper lip of the calyx large, flightly three-toothed, each of the teeth bearing a feeble fpine; lower one narrow, deeply bifid, fimilarly fpinous; anthers crefted at the back. La Marck never obferved the filaments fpinous as defcribed by Linnæus. *Seeds* roundifh, turgidly lenticular, mucronate at the bafe, rufefcent, with a white umbilicus, fhaped like the letter *y*. A native of Spain and Portugal. It differs little from prunella, except in its four-cleft ftigma, and laciniated bractes; characters which La Marck, Juffieu, and Ventenat have not thought fufficient to conftitute a generic diftinction.

CLEOPATRA, in *Biography*, the name of feveral princeffes and queens of Egypt. Of thefe we fhall felect

CLEOPATRA III., queen of Egypt, the eldeft daughter of Ptolemy Auletes, who gave his crown to her and her brother Ptolemy (Dionyfius II.) and ordered by his will, that they fhould marry together, according to the cuftom of that houfe, and govern jointly. And becaufe they were both very young, the daughter, who was the eldeft, being only 17 years of age, he left them under the tuition of the Roman fenate. She afcended the throne in the fecond year of the 182d olympiad, the 703d year of Rome, and the 51ft year before Chrift. Little is known of the beginning of Cleopatra's and her brother's reign. Ptolemy, being a minor, under the tuition of Pothinus, an eunuch, and Achillas, commander in chief of the Egyptian forces, thefe two ministers engrossed the whole power to themselves, and in the king's name, deprived Cleopatra of her share in the sovereignty left her by the will of her father. Thus injured, she retired into Syria, and having raised in that country and in Palestine a considerable army, led it into Egypt, in order to assert her right by military force. Ptolemy also, having collected all the forces in his power, took the field and marched against his sister. Both armies encamped between Pelusium and Mount Casius; but declined hazarding an engagement. At this conjuncture of the difference between the brother and sister, Pompey, whom the people had appointed guardian to the young king, after his defeat at Pharsalia, sought an asylum in Egypt, but on his arrival off Pelusium, he was basely murdered by the council of the reigning ministers and that of Theodotus, a rhetorician, who was the king's preceptor. In the mean time Cæsar, in his pursuit of Pompey, arrived at Alexandria, and there hearing of his death, caused him to be interred with all the usual solemnities. During his detention in this city by the Etesian winds, he solicited the payment of the money due to him from Auletes, and took cognizance of the difference subsisting between Ptolemy and his sister Cleopatra. The rigour with which the money was exacted for the payment of Auletes' debt, and the haughty manner in which Cæsar conducted himself in arbitrating between Ptolemy and his sister, incensed the Egyptians against him; but their indignation was appeased by concession and explanation on the part of the Roman, and the cause being brought before his tribunal, advocates were appointed to state the respective claims of the brother and sister. Cleopatra, in the mean while, justly apprehending that female youth and beauty would make an impression upon Cæsar in her favour, determined on an attempt to attach him first to her person and then to her cause. Having obtained leave to appear before Cæsar, or as Plutarch says, having been invited to plead her own cause in his presence, she concerted measures for being secretly conveyed into his apartment; and for this purpose caused herself to be tied up in a mattrass, and carried thither through the streets of Alexandria on the back of Apollodorus. Cæsar applauded the stratagem, and when Cleopatra presented herself, he was charmed with her person and detained her all night. Such was her influence over him, that he next morning sent for Ptolemy, and pressed him to receive his sister upon her own terms. When the young prince found that Cæsar, instead of being an impartial judge, was become the advocate of Cleopatra, and that she had taken up her abode in that part of the palace where the Roman lodged, his indignation was roused, and running through the streets of Alexandria in a frantic manner, he excited an insurrection of the populace against Cæsar. The Roman, however, contrived to repel the attack that was made upon his palace and to appease the tumult, by shewing himself from a balcony to the enraged multitude, and promising to do whatever they should think fit to suggest. On the following day he convened a general assembly of the people, and as guardian and arbitrator, he decreed that Ptolemy and Cleopatra should reign jointly in Egypt, agreeably to their father's will, which he had caused to be publicly read. Cæsar's decree gave general satisfaction; but Pothinus, whose interest and power were likely to be materially affected by it, inspired the people with new jealousies, and suggested to them that it was part of the plan of the Roman dictator, however disguised, to place Cleopatra alone on the throne. The reports to this purpose which he industriously circulated excited a fresh disturbance among the populace, and measures were adopted for expelling Cæsar from the city. The contest on both sides was active and violent; but Cæsar prevailed. Having secured the person of the king, and caused Pothinus to be put to death, he gained several victories over the Egyptians; and after his last victory, on occasion of which 20,000 Egyptians were slain, 12,000 taken prisoners, and Ptolemy drowned in the Nile in his attempt to escape, Cæsar returned to Alexandria, and entering the city without opposition, bestowed the crown on Cleopatra, obliging her to marry Ptolemy, her younger brother, at that time no more than 11 years of age. When this object was accomplished, Cæsar was roused from the lethargy into which he had been lulled by Cleopatra's charms, by the success of Pharnaces, king of the Cimmerian Bosphorus, in the recovery of his father's dominions; and accordingly he left part of his forces in Egypt to protect Cleopatra, and with the rest marched into Syria. Cleopatra remained undisturbed in the possession of the crown, but dreading the interference of her brother, when he attained his 15th year, at which age, according to the laws of the country, he was to share the royal authority as well as the name, she caused him to be poisoned, in the fourth year of his reign, and from that time she became the sole sovereign of Egypt. After the death of Cæsar, when the triumvirate was formed, Cleopatra declared herself in its favour; and being delivered from all apprehensions of an invasion, she sailed with a numerous fleet to join Antony and Octavianus; but was prevented by illness from prosecuting her design and obliged to return to Egypt, after having lost a great number of her ships by a storm.

Antony, after the battle of Philippi, having received information that Cleopatra, or some of her governors, had sent succours to Cassius against Dolabella, summoned her to appear before him at Tarsus in Cilicia. The queen, confiding in the power of her charms, already experienced, flattered herself that, at the age of 25 years, when the improvement of her understanding would render her conversation no less agreeable than her person, she should be able to captivate Antony. Having provided herself with rich presents, large sums of money, and magnificent habits and ornaments, she embarked in a stately galley, attended with the rest of her fleet, and crossing the sea of Pamphylia, and entering the Cydnus, arrived at Tarsus, where Antony waited her arrival. Her galley was all over gilt, the sails were of purple, and the oars plated with silver. The queen appeared under a canopy of cloth of gold, raised on the deck, in an attire and attitude resembling those in which Venus was generally painted, surrounded by a great number of comely youths fanning her like Cupids, and beautiful virgins, representing, some of them the Nereids, and others the Graces. The dales and hills echoed, as she sailed up the river, with the melodious sounds of various instruments, with which the oars keeping time, increased the harmony. The perfumes, that were burnt on the deck in great abundance, diffused their odours on each side of the river to a considerable distance, and filled the air with fragrance. As she drew near the city, curiosity induced crowds of citizens to abandon their houses and occupations, and to go out to meet her; and Antony, who was distributing justice in the forum, found himself deserted. Upon her landing, Antony invited her to supper; but the queen, observing the decorum usual on these occasions, declined accepting his invitation, and requested a visit from him in the tent, which would be soon pitched on the banks of the river. Antony instantly complied, and was entertained with a magnificence which no words can adequately describe. At this first interview, he was no less charmed by her conversation than by her form and features; and such was the ascendant which she had gained over him, that it

was

was not in his power to refuse her any thing she asked, however repugnant to the laws of justice, humanity, or religion. At her request assassins were dispatched to murder her sister Arsinoe; and in order to increase and perpetuate her influence over the deluded Antony, she spent immense sums of money in the entertainments she prepared for him and the chief officers of his army. On one occasion, she presented him with a vast number of gold cups, enriched with jewels, which he admired; and on another, she gave him all the gold and silver plate which had been used during a sumptuous banquet. At one of these entertainments the queen had ear-rings consisting of two of the finest and largest pearls that ever had been seen, each valued at 52,500 *l.* of our money. One of these she caused to be dissolved in vinegar, and then swallowed it, in order to shew in what low estimation she held such toys, and how much she could spend in one draught. She was also preparing to dispose of the other in the same way, when Plancus stopped her, and saved the pearl, which was afterwards carried to Rome by Augustus, and being cut in two by his orders, it served for pendants to the Venus of the Julian family. (Pliny, l. xxxiii. cap. 3.) For a further account of the connection between Antony and Cleopatra, see the article ANTONY. This connection inspired her with the hope of becoming one day queen of Rome; for we are told by Dio Cassius and Eutropius, that her usual oath was, "as I hope to give law in the capitol." When Antony and Cleopatra separated after the disastrous battle of Actium, the former went to Libya, and the queen sailed to Alexandria. Fearing, however, that she might not be received by her subjects, if her misfortunes were known, she entered the harbour with crowns on the prows of her ships, as if she had obtained some signal victory. This artifice succeeded; and having gained admission into her capital, she put to death all who were averse to her, in order to prevent the tumults, which she apprehended they might occasion, when the true state of their affairs should be known. Antony, who arrived in Egypt soon after the queen, by whom he was infatuated, was astonished to hear of a very extraordinary undertaking in which she was engaged. As she expected Octavianus to pursue her into Egypt, in order to avoid falling into his hands, she concerted measures for the transportation of her ships from the Mediterranean into the Red Sea, over the isthmus, of 70 miles, which lay between them. These ships were to be joined to those in the Red Sea, and all her treasures on board of them, she determined to seek some place of settlement, out of the reach of the enemy. But the Arabians on the coast disconcerted her plan, by burning all her ships; and she was, therefore, forced to abandon her enterprise. After the death of Antony, Cleopatra was taken, having been prevented from dispatching herself with a dagger, which she always carried about with her for this purpose; and being introduced to Octavianus on his arrival at Alexandria, obtained the only favour she asked, which was leave to bury Antony. She afterwards made an attempt to captivate and delude Octavianus; but her efforts were ineffectual, for after she had done speaking, he returned her this laconic answer, "Woman, be of good cheer; no harm shall be done you!" Cleopatra observed his coldness and indifference, but dissembled the concern which they occasioned; and expressing her gratitude for the favour he had conferred upon her, she put into his hand an inventory of all her moveables, jewels, and revenues, which she designed for his use. When Seleucus reproached her for having concealed part of her most valuable effects, she flew at him in a violent rage, and gave him several blows in the face. Then turning to Octavianus, she said, "Is it not very hard, since you have condescended to visit me in my present condition, that one of my own servants should thus insult me in your presence? I have, it is true, reserved some jewels, not to adorn my own person, but as a present intended for your sister Octavia, and wife Livia, that by their intercession you may be induced to treat an unfortunate prisoner with more favour and kindness." Octavianus, apprehending from this conversation that she had no thoughts of destroying herself, desired her to dispose of the jewels she had reserved according to her own wishes, and assured her that she should be treated with a greater degree of kindness and generosity than she expected. Cleopatra, however, was not deceived by these professions. She had no doubt of Octavianus's intention to make her serve as an ornament to his triumph; and she determined to avoid that ignominy by a voluntary death. To prevent it she was constantly watched by Epaphroditus; but in hopes of obtaining a fit opportunity for executing her purpose, she obtained leave to pay her last tribute of respect to the tomb of Antony. She bathed it with her tears, covered it with flowers, and with many sighs and lamentations performed the ceremonies that were customary among the Egyptians on such occasions. After her return, a messenger was deputed by Cornelius Dolabella, who was the intimate friend of Octavianus, and who, nevertheless, being in love with Cleopatra, had promised to give her timely notice of his designs respecting her, in order to inform her, that, within three days, she and her children would be put on board a vessel that was in the harbour, and conveyed by sea to Rome. Upon this intimation, she ordered a splendid entertainment to be prepared, and having invited some of her friends appeared more cheerful than usual during the feast. Rising suddenly from table, she delivered to Epaphroditus a sealed letter for Octavianus, requesting that it might be immediately conveyed into his own hands. Having thus contrived to get him out of the way, she withdrew to her apartment, attended by two of her women, and having dressed herself in her royal robes, she lay down on the bed, and asked for a basket of figs, which one of her faithful servants had brought her in the disguise of a peasant. Among the figs was concealed an asp, the poison of which was such that those who were bitten by it fell immediately into a kind of lethargy, and died without any pain or uneasiness. (On this subject see the article ASP.) The purport of her letter to Octavianus was that he would permit her to be buried in the same tomb with Antony. Conceiving from this request that she meant to lay violent hands on herself, he dispatched some of his friends in haste to prevent it, if possible. Upon their entrance into the apartment of Cleopatra, they found her lying dead on a golden bed in her royal robes; one of her maids likewise being dead at her feet, and the other ready to expire. Octavianus, as soon as he heard the news, lost no time in using all possible means for her recovery; but they were altogether ineffectual. Thus deprived of the chief glory and ornament of his triumph, he, however, granted her last request, and commanded that she should be buried with all possible pomp in the same tomb with Antony.

> "Ausa et jacentem visere regiam
> Vultu sereno fortis, et asperas
> Tractare serpentes, ut atrum
> Corpore combiberet venenum,
> Deliberata morte ferocior:
> Sævis liburnis scilicet invidens,
> Privata deduci superbo
> Non humilis mulier triumpho."

Hor. Od. 37. l. 1.

"Not

C L E

"Not the dark palace of the realms below
Can awe the furious purpoſe of her ſoul;
Calmly ſhe looks from her ſuperior woe,
That can both death, and fear control:
Provokes the ſerpent's ſting, his rage diſdains,
And joys to feel the poiſon in her veins.
Invidious to the victor's fancy'd pride,
She will not from her own deſcend,
Diſgrac'd, a vulgar captive, by his ſide,
His pompous triumph to attend;
But fiercely flies to death, and bids her ſorrows end."

Thus died Cleopatra, at 39 years of age, after ſhe had reigned, from the death of her father, 22 years. She was a woman of extraordinary talents, and of boundleſs ambition. She is ſaid to have been well acquainted with Greek and Latin, and to have ſpoken with eaſe and readineſs many other languages, converſing with the Ethiopians, Troglodites, Jews, Arabians, Syrians, Medes, and Perſians, without an interpreter. In the midſt of the career of ambition and licentious pleaſure which ſhe purſued, ſhe retained a taſte for polite literature, and erected in the place where the famous library of Alexandria ſtood, a new one, not inferior to the former; enriching it with the 200,000 volumes of the library of Pergamus, with which Antony had preſented her. With her terminated the family of Ptolemy Lagus, the founder of the Egyptian monarchy, after it had ruled over Egypt, from the death of Alexander, 294 years, or as others affirm, 293 years and three months. From this time Egypt was reduced to a Roman province, and governed by a prætor ſent thither from Rome. Anc. Un. Hiſt. vol. viii. Rollin's Anc. Hiſt. vol. vii.

Cleopatra's *Needles*, in *Ancient Architecture*, are two obeliſks towards the eaſtern part of the palace of Alexandria, in Egypt; they are conſtructed of Thebaic ſtone, and covered with hieroglyphics; one is overturned, broken, and lying under the ſand; the other is on its pedeſtal. Theſe two obeliſks, each of them of a ſingle ſtone, are about 60 feet high, by 7 feet ſquare at the baſe.

CLEOPATRIS, in *Ancient Geography*, a town of Egypt, ſeated on the canal which paſſes from the Nile to the Red Sea. See Arsinoe.

CLEOPHORA, in *Botany*, (from κλεος, *ſplendor*, and φορος, *ferens*, denoting a tree with a ſplendid ſpadix), Gært. 701. (Latania, Juſſ. p. 39. Comerſ. MSS.) Nat. Ord. *Palmæ*.

Gen. Ch. Male and female flowers on different plants. *Male. Calyx common*, ſpathe many-leaved; leaves imbricated; ſpadix branched; branches ſomewhat cylindrical, digitate-cleft at the top; clefts having the form of an Amentum, covered with ſmall imbricated one-flowered ſcales. *Cal. proper* ſix-parted; outer ſegments ſmaller. *Stam.* fixteen, united at the baſe. Fem. Spatha . . . Spadix. *Calyx* ſix-leaved. *Berry* (or drupe) globular, one-celled, containing three pyrenes or ſtones.

Sp. C. *lontaroides*, Gært. tab. 120. fig. 1. "Leaves palmate-pinnatifid; petiole without prickles." *Berry* obſoletely trigonous, ſmooth; rind coriaceous, thin, brittle, and almoſt cruſtaceous when old; pulp ſucculent, fugacious, drying into membranous ſcoriæ, adhering to the pyrenes or ſtones, without any veſtige of fibres or partitions; oſſicles, or ſtones, three, cruſtaceous, thin, convex and obſoletely ſtriated on one ſide, angular, and ſmoothiſh on the other. *Seeds* one in each oſſicle, ſomewhat elliptical, thick, very finely and irregularly ſtriated, pulverulent, ſomewhat convex on one ſide, obſoletely angular on the other, ending beneath in a ſhort point, marked above a little behind the apex, with a ſmall papilla which covers the embryo. Gært. A native of the Iſle of France.

CLEOSTRATUS, in *Biography*, an ancient mathematician and aſtronomer of Tenedos, who flouriſhed about 533 years B.C. and firſt formed, as it is ſaid, the ſigns of the zodiac, and reformed the Grecian calendar.

CLEPSYDRA, in *Ancient Geography*, a fountain of Peloponneſus, in Meſſenia, placed by Pauſanias and Appian in mount Ithome.

Clepsydra, ſo called from κλεπτω, *ſurripio*, and ὕδωρ, *aqua*, was an horological inſtrument of great antiquity, among the Egyptians and other eaſtern nations, probably before ſun-dials were invented; though the name of the original inventor is not handed down to us; the conſtruction has been varied in different ages and countries, according to the variation of the different modes of reckoning time, but one principle is the baſis of all the forms it has undergone, namely, the conſtant dropping, or running of water through a ſmall aperture, out of one veſſel into another. At firſt the indication of time was effected by marks correſponding to either the diminution of the fluid in the containing veſſel, during the time of emptying, or to the increaſe of the fluid in the receiving veſſel during its time of filling; but it was ſoon found, that the eſcape of the water was much more rapid out of the containing veſſel, when it was full, than when it was nearly empty, owing to the difference of preſſures at different heights of the ſurface; this irregularity in the dropping, preſented an obſtacle which required much ingenuity to correct. In our account of the different conſtructions of clepſydræ, we will claſs them under the two heads of *ancient* and *modern*.

Ancient Clepſydræ.—According to M. Vitruvius Pollio, the firſt improver of the ancient clepſydra, or water-clock, was Cteſibius of Alexandria, the ſon of a barber, who, about 245 years before Chriſt, ſpent much time in deviſing mechanical contrivances for removing not only the obſtacle in queſtion, but alſo another equally formidable one, which aroſe from the daily inequality of the Egyptian hours. As one-twelfth part of the time elapſed from ſun-riſe to ſun-ſetting on any day, was called an hour of that day; and as one-twelfth part of the time that paſſed from ſun-ſetting to ſun-riſe, was called an hour of the night; not only did the hours of day differ from the hours of night, but from one another, at all times, except at the vernal and autumnal equinoxes; hence it became neceſſary, either to make the water fall irregularly into a receiving veſſel, with equidiſtant hour-marks, or to have varying hour-marks for a regular efflux; the firſt of theſe methods (which probably preceded that of Cteſibius) was thus effected, *viz.* 1. A conical hollow veſſel, A, was inverted, or placed like a funnel in a frame C C (*Plate* I. *fig.* 1. of *Horology*) there being a very ſmall aperture at the apex of the cone, and another ſolid cone, B, every way ſimilar as to dimenſions, was plunged into the hollow one, when filled with water to a greater or a ſmaller depth, accordingly as the efflux was wanted to be more or leſs rapid, and then adjuſting marks, correſponding to every day and night in the year, were put on a long ſtem D, inſerted into the broad end of the ſolid cone B, and kept in its poſition by the frame, as repreſented in the figure, to ſhow how much the inner cone was to be depreſſed or elevated, to accelerate or retard the iſſue of the fluid for the correſponding time; H was the ſpout which ſupplied a conſtant influx of water, and I the waſte pipe, connected with the top of the conical veſſel, which carried off the ſuperfluous water; hence the conſtant influx of water preſerved an unvarying height of the ſurface from the aperture, which aperture was varied at pleaſure, by the elevation or depreſſion of the inner cone; if if now we ſuppoſe the ſubjacent veſſel to be a cube, cylinder, or any other regular figure, and equidiſtant hour-marks to be properly made on its ſide, the ſurface of the water, or an index borne by it on a piece of cork, would, as it roſe, indicate the hours correſponding to thoſe marks.

The imperfections of this clepſydra were theſe: 1. It required two daily manual adjuſtments, one in the morning, and the other in the evening; and, 2. It made no allowance for the variation of fluidity, in different degrees of temperature, which, it is aſſerted (but perhaps without proof), greatly influenced the iſochroniſm of the drops. As an improvement, or rather appendage, to this conſtruction of the clepſydra, a bar, E E, with rack-work at the upper end, as ſhewn by the dotted lines, was made to float on the ſurface of the lower veſſel by means of an affixed piece of cork, F, ſo that as the cork and its bar roſe in the veſſel, the teeth of the bar turned a ſmall wheel, G, fixed to the upper part of the frame by a cock, on the arbor of which wheel a hand was put, which revolved and indicated the hours on a fixed dial-plate. This addition, however, did not render the inſtrument a more accurate meaſure of time, but only indicated the hours, ſuch as they were, in an improved manner. It may be worthy of remark here, that water was at once the regulator and the maintaining power of the inſtrument before us; the interval between two ſucceſſive drops was to the clepſydra what one vibration of the pendulum is to a clock, or one oſcillation of the balance is to a watch; and the floating of the indented bar was in place of a weight or ſpring to move the wheel to which the hand was attached; conſequently it might be ſaid to be an horological machine of the ſimpleſt conſtruction poſſible. The adjuſtment of the two cones was regulated by the latitude of the place, owing to the manner in which the hours were divided; at Alexandria, for inſtance, the greateſt and leaſt velocity of the drops were required to be to each other as 70 to 50, the longeſt and ſhorteſt hours in that latitude being reſpectively $1^{h}\ 10^{m}$ and 50^{m} of equable time; and in higher latitudes the diſparity is ſtill greater.

2. The next attempt to improve the clepſydra was by conſtructing it ſo that its aperture was adjuſted, as the year advanced, by the putting of an index to the ſun's place in an ecliptic circle; which attempt, of courſe, rendered the inſtrument more complex. Perrault conceives the parts to have been thus adapted, according to the deſcription given of it by M. Vitruvius Pollio, in his book "De Architecturâ" (cap. ix. lib. ix.).

Fig. 2. of *Plate* I. repreſents an ancient clepſydra with an horary circle and a variable aperture: A is a reſervoir, to the top of which is attached a water-pipe, not ſeen in the drawing, to preſerve an equal preſſure by carrying off the ſuperfluous water; B is a pipe projecting from the reſervoir into the upper part of the drum, M N, on the front of which drum the ecliptic circle is marked; O D L is a ſmaller inner drum, which revolves on a tubed arbor, F, and which is repreſented as drawn out of its place; this ſmall drum has a thorough groove, *a b*, varying in breadth all round it, like a hoop tapering throughout from the broadeſt part both ways to its oppoſite point, and is of ſuch a diameter that the middle of the groove juſt reaches to, and coincides with, a perforation under the tube, B, at the upper part of the great drum, ſo that, as the little drum, which carries the diurnal index, L, and nocturnal index, O, oppoſite to the former, is turned round by hand, the variation in the breadth of the groove occaſions a correſponding variation in the velocity of the efflux of water, by making a larger or ſmaller aperture, accordingly as the ſun's place is more or leſs advanced in the ecliptic, the largeſt aperture being when the diurnal index is at the beginning of Capricorn; a little baſon or funnel attached to the upper part of the fixed tube or hollow arbor, F, (not viſible), receives the water in its fall within the drum, and tranſmits it through the ſaid tube by G into the receiving veſſel, H, in which is floated the piece of cork, I; this floating-piece is connected, by a chain, with the counterpoiſe, K, after it is folded round the arbor, P, which carries the hour-hand of the dial-plate; conſequently, as the water riſes in the veſſel, H, the piece, I, is raiſed, and its counterpoiſe, K, at the ſame time falling gives motion to the arbor and hour-hand, and the hours are longer or ſhorter according to the breadth of the groove which is at any time under the perforation of the tube, B, *i. e.* according to the place in the ecliptic to which the proper index is put.

This clepſydra, like the preceding one, compoſed of two cones, requires two manual adjuſtments, one in the morning and the other in the evening, and makes no allowance for the (ſuppoſed) variation of fluidity occaſioned by the different ſtates of the weather; and the variation in the breadth of the groove or ſlit, it is preſumed, was more plauſible in theory, than feaſible in practice; the contrivance, however, was ingenious, and beſpoke the inventor's acquaintance with aſtronomy.

3. The next improvement in the ancient clepſydra was probably that of Cteſibius, which was an automaton, or ſelf-adjuſting machine, and is repreſented by *fig.* 3, which, according to Perrault and Ferd. Berthoud, exhibits the interior conſtruction of this machine; A is the end of a tube over which an image ſtands, which is connected with a full reſervoir, and from the eyes of which, conſidered as invariable apertures, the water continually flows or drops in a regulated manner into it; this tube conveys the water from M towards B into the top of a long regular veſſel, B C D F, which it gradually fills, and raiſes the cork, D, with its attached light pillar, C D; on the top of this pillar is ſurmounted another image holding an index which points to the diviſions on the large column above. Now, when the water riſes in the veſſel that contains the cork, it alſo riſes in the ſmall tube, F B, which conſtitutes one leg of a ſyphon, F B E, that is connected with the bottom of the cubic veſſel; conſequently, when the index has mounted to the uppermoſt diviſion on the large column of hour lines, conſiſting of twice twelve, the water flows over the bent part, B, of the ſyphon, and immediately empties the veſſel into one of the ſix troughs or diviſions of the water-wheel, K, which is thus turned one-ſixth part of a revolution, during which time the image falls with its index to the bottom of the column, to be ready for the next day. This portion of the mechaniſm would have been ſufficient to conſtitute the machine, if the hours had been conſidered as of equal length throughout the year, but the Egyptian mode of dividing and reckoning time made it requiſite that the hour lines ſhould ſlope out of an horizontal direction on the ſurface of the column, ſo as to make variable ſpaces, and alſo that the column ſhould revolve once in a year, to preſent all the variations of ſpace to the index. This annual motion of the column is ſaid to be effected by wheel-work in the following manner:—on the arbor of the water-wheel, K, is fixed the pinion, N, of ſix leaves, which impels the contrate-wheel, I, of 60 teeth in $6 \times \frac{60}{6} = 60$ days, then on the perpendicular arbor of I is another pinion, H, of ten leaves, which drives the wheel, G, of 61 teeth round in $60 \times \frac{61}{10} = 366$ days, and along with it the horary column, into which its arbor is inſerted at L. On the bottom of the column is marked an ecliptic circle; and 12 perpendicular lines drawn lengthwiſe down the column divide it

it into the respective signs, which are serviceable for ascertaining the requisite shape of the hour lines in any month. The writer of this article, however, suspects, that the above train of wheel-work is only what Perrault, the translator of Vitruvius, supposed to be that of Ctesibius; for, on referring to the original account of Vitruvius, the year in which the column revolved is stated to be 365 days, a period which might be effected thus:

Let the water-wheel have only five compartments instead of six, and let an endless screw be cut on its arbor to impel a wheel of 73 teeth, with a perpendicular arbor, to be inserted into the column of hours, which will, by such a simple construction, revolve in $5 \times \frac{73}{1} = 365$ days, agreeably to the original account.

The clepsydra, in one of its earlier forms, was used as an astronomical instrument, by the help of which the equator was divided into twelve equal parts, before the mathematical division of a circle was understood: it was deemed of more value than a sun-dial, on account of its dividing the hours of the night as well as of the day. It was introduced into Greece by Plato, and into Rome by P. Cornelius Scipio Nasica, about 157 years before Christ.

Pliny says (lib. xxxvii.) that Pompey brought a valuable one among his spoils from the Eastern nations; and Cæsar is said to have met with an instrument of this kind in England, by the help of which he observed that the summer nights of this climate are shorter than they are in Italy. The use which Pompey made of his instrument was to limit the speeches of the Roman orators; which Cicero alludes to when he says "latrare ad clepsydram."

4. Besides the ancient clepsydra, above described, F. Berthoud mentions another (Histoire de la Mesure du Temps, tom. I. p. 20.), which was called the *anaphoric*, on the dial-plate of which were projected the circles of the sphere, including the parallels of the sun's altitude, with the semi-diurnal and semi-nocturnal arcs, to which an adjustable bead, as the sun's representative, pointed as an index to shew the hours, parallels, &c. as the dial-plate revolved daily by means of wheel-work, which was impelled by water. It does not seem certain at what period this instrument was invented and used; but Berthoud thinks that tables of the sun's motion must have existed previously to its invention, and also a knowledge of projections of the sphere on a plane surface, whence he fixes the date posterior to the time of Hipparchus, who, according to Pliny, died about 125 years B.C. The name *anaphoric* is evidently derived from *anaphora*, which was the second house in the heavens, according to the doctrine of astrology, which prevailed about the time here specified.

In Athenæus, lib. iv. p. 174, we have a history and description of an ancient instrument. He tells us that it was invented in the time of the second Ptolemy Euergetes, by Ctesibius, a native of Alexandria, and by profession a barber: or rather, that it was improved by him, for Plato furnished the first idea of the hydraulic organ, by inventing a night-clock, which was a clepsydra, or water-clock, that played upon flutes the hours of the night at a time when they could not be seen on the index.

The anecdote in Athenæus concerning the mechanical amusements of the great ideal philosopher, is curious. What a condescension in the *divine* Plato to stoop to the invention of any thing useful! This musical clock must have been wholly played by mechanism.

In describing it, Athenæus says, it resembled in appearance a round altar; but was not to be ranked with stringed but wind instruments, composed of pipes; the orifices of which being towards the water, when it was agitated, produced from the pipes, by its fall, a soft and pleasing sound.

Modern Clepsydræ.—The modern method of dividing the natural day into 24 solar hours of equal length, has rendered the preceding constructions of the clepsydra useless for some centuries back; and, notwithstanding the science of hydrostatics is much better understood by the modern than it was by the ancient philosopher, so that a scale of altitudes corresponding to the variable velocities of the efflux of a fluid out of a given aperture can be ascertained by calculation for a containing vessel of any capacity or figure, yet, since the happy inventions of the balance and pendulum, as regulators of watches and clocks, horological machines, actuated by the motion of water, have become so rare, as to be considered as objects only of curiosity.

Beckmann, in his "History of Inventions," vol. i. p. 136. attributes the contrivance and introduction of a water-clock to some time between 1643 and 1663, and gives nearly the same brief account of one as we meet with in "Bion, on Mathematical Instruments," and also in "Ozanam's Recreations," edited by Dr. Hutton, the last of which authors said, in the year 1693, that the first water-clock brought to Paris about that time was from Burgundy. He also says, that father Timothy, a Barnabite, had given the machine all the excellence it was capable of, by constructing it so as to make it go a month at one winding up, and to exhibit not only the hours on a dial-plate, but also the sun's place, day of the month, and festivals throughout the year.

How these and similar particulars might be indicated, will be easily apprehended from the following description, which is agreeable to the accounts given of a water-clock of the 17th century by the authors already named.

1. In *fig.* 1, of *Plate* II. of *Horology*, A B C D is an oblong frame of wood, to the upper part of which two cords, A *a* and B *b*, are fixed at their superior extremities, and at their inferior, to the metallic arbor, *a b*, of the drum, E, which contains distilled water; this water is confined in cells so peculiarly constructed, that they regulate the velocity with which the drum shall descend by the force of gravity from the top to the bottom of the frame, and the ends of the arbor indicate the hours marked on the vertical plane of the frame during the time of descent. An observer, who knows not the nature of the interior cells of the drum, is surprised to see that its weight does not make it run down rapidly, when mounted to the top of the frame by merely folding the strings round the arbor, there being apparently no mechanical impediment to the natural action of gravity. To explain how this phenomenon is produced, we must refer to *fig.* 2, which is a section of the drum at right angles to its arbor; this circular plane we will suppose to be six inches, which is about the usual size, in diameter, and to represent the inner surface of either of the two ends of the drum, which may be made of any of the unoxidable metals; then, if we conceive seven metallic partitions, F *f*, G *g*, H *h*, I *i*, K *k*, L *l*, and M *m*, to be closely soldered to both ends of the drum, in the sloping direction indicated by the figure, where the black lines are equidistant tangents to the small dotted circle of an inch and half diameter at the points *f*, *g*, *h*, &c.; it is evident, that any small quantity of water introduced into the drum would fall into two, or at most three, of the lower compartments, and would remain there until some external force should alter the position of the drum, supposing in this case the cords tied fast to the arbor; but we have said that they are wound round the circumference of an arbor, that has a sensible diameter, suppose one-eighth of an inch; therefore, they

they are removed one-ſixteenth of an inch, or upwards, if we take their thickneſs into the account, from the centre of the drum, which would alſo be its centre of gravity, if it were empty, on which account it would, in that caſe, revolve to the left, in the direction F G H downwards, from the cord being at the remote ſide of the centre, as repreſented by N O; but conceive the water to be included now and then, it would be elevated to the right, till its weight became a counterpoiſe to the gravity of the heavier ſide of ths drum, in which ſituation all motion would ceaſe, and the drum would remain, ſuſpended, indeed, by the cords, but in a ſtate of equilibrio. Conceive again a ſmall hole perforated in the partition preſſed upon by the water near the circumference of the large circle, and alſo at the points F, G, H, I, K, L, M, and the conſequence will be, that the water will firſt force its way ſlowly through the perforation at K, from the more elevated to the lower compartment, which effect will diminiſh its power as a counterpoiſe, and give ſuch an advantage to the heavy ſide, F G H, of the drum, conſidered as empty, as will occaſion a ſmall degree of motion towards the left, and conſequently carry the water once more towards the right; but now the water paſſes through the perforation of the next partition alſo at I, and produces again the ſame effect, as has been deſcribed with reſpect to K, and will continue to do ſo, at the ſucceſſive perforations, till all the compartments have been filled and emptied by means of theſe perforations, in ſucceſſion, which kind of motion of the drum, contrary to that of the water, it is now not difficult to conceive will be pretty regular, if all the partitions are perforated exactly alike. The difference of the preſſures of the water in cells, nearly full and nearly empty, will occaſion ſome little deviation from regularity; but theſe will be periodic, and muſt be allowed for in the hour diviſions, which ought to be made by a compariſon of the ſpaces fallen through, with the time indicated by a clock or watch. About nine ounces of diſtilled water will ſuffice for a clepſydra of ſix inches diameter, and two inches depth, and the velocity of the fall may be limited, either by varying the quantity of water, or by hanging a ſmall metallic cup F, to receive weights, by a cord wound in a direction contrary to the cords of ſuſpenſion, to act as a counterpoiſe in aid of the water, if the fall be too rapid, or *vice verſâ*.

It is abſolutely neceſſary that the arbor ſhould fit the central ſquare hole ſo well as to prevent the eſcape of water from the drum, otherwiſe the inſtrument would continue to gain velocity, till at length it would no longer afford a true indication of time.

Sometimes a cord, *cd*, with a weight, P, is made to paſs round a pulley fixed to an arbor at the top of the frame, with a nooſe paſſing over the axis near *a*, as is ſeen in the ſame figure, which arbor, projecting through a dial-plate or face, turns round and carries a hand to indicate the hours like an ordinary clock; when this conſtruction is preferred, it is an indiſpenſable requiſite that the circumference of the pulley's groove be exactly of the ſame dimenſions as the fall of the drum in 12 or 24 hours, accordingly as the dial is divided.

This clepſydra, it is ſaid, goes faſter in ſummer than in winter, which is owing to the drum being relatively heavier in rarefied than in denſe air; we can hardly ſuppoſe that any alteration in the fluidity of the water, as formerly ſuppoſed, would make any difference. The minute hand and alſo the ſtriking part of a common clock might eaſily be ſuperadded to this clepſydra.

2. Another form, and that a very ſimple one, of the modern clepſydra has derived its origin from that law in hydroſtatics by which the efflux of water out of an orifice is influenced under different preſſures, or which is the ſame thing, at different depths from the ſurface, the velocity being directly as the ſquare root of the height of the ſurface from the aperture. If a glaſs veſſel, like that in *fig*. 3, therefore be taken, out of which all the water will flow in exactly 12 hours, from a ſmall aperture in its lower extremity, the whole height muſt be divided, or ſuppoſed to be divided, into the ſquare of 12 or 144 equal parts, of which parts 11 × 11, or 121 meaſured from the bottom, or 23 meaſured from the top, will give the diviſion for the hour 11, 10 × 10 or 100 from the bottom will give the line for 10, 81 for 9, 64 for 8, and ſo on down to the bottom, as repreſented in the figure; which ſcale is in the inverted proportion of that according to which heavy bodies fall in free ſpace by the ſole force of gravity.

If, inſtead of the veſſel itſelf being divided by hour-lines as above directed, the ſtem of a floating piece like an hydrometer were to have a ſimilar ſcale kept in a perpendicular direction, by paſſing through the central hole of a cap or cover of the veſſel, the indication of time would be made on the ſtem at the ſurface of the cap, which conſtruction would admit of the veſſel being of wood or metal.

3. But ſuch a figure might be given to the containing veſſel as would require the dividing marks to be equi-diſtant, which Dr. Hutton, in his recent edition of "Ozanam's Recreations," has aſſerted to be a paraboloid, or veſſel, formed by the circumvolution of a parabola of the fourth degree, the method of deſcribing which, he has given thus:

Let A B S, *Plate* II. *fig*. 4, be a common parabola, the axis of which is P S, and the ſummit S. Draw, in any manner, the line, R v T, parallel to that axis, and then draw any ordinate of the parabola A P, interſecting R T in R; make P Q a mean proportional between P R and P A, and let pq be a mean proportional alſo between pr and pa; and ſo on. The curve paſſing through all the points Q q, &c. will be the one required, which, being made the mould for a veſſel to be caſt by, will produce an inſtrument, which, when perforated at the apex, will have the ſingular property of equalizing the ſcale, ſo as to correſpond to equal times while the water is running out. Mr. Varignon has given a geometrical and general method of determining the ſcale for a clepſydra, whatever may be the ſhape and magnitude of the veſſel. (See "Memoires de l'Academié Royale des Sciences," p. 78, 1699.)

4. Another method of making a water-clock with equi-diſtant hour lines in any regular veſſel, is effected more ſimply than in the preceding one, by means of the ſyphon fixed faſt in the centre of a broad piece of cork, which is floated in any regular veſſel, as the cylindrical one at *fig*. 5, for as the power of a ſyphon to empty any veſſel filled with water depends upon the difference of atmoſpheric preſſures at the ſurface of the water and at the orifice of the longer leg, it is clear that while the ſhorter leg ſinks with the ſurface of the water in the veſſel during its time of emptying, the relative preſſures, depending on the diſtance from the ſurface of the water to the orifice of the lower leg, will continue unaltered in any ſtate of the atmoſphere; hence equal portions of water will be diſcharged in equal times; and a light cock cemented on the lower orifice would afford a means of adjuſting its aperture to the ſize of any veſſel that may be fixed upon; or otherwiſe a ſecond receiving veſſel may be divided into equal ſpaces for the hours, which would in this caſe be indicated by the ſurface of the riſing water.

Beſides the preceding methods of meaſuring time by means of water, there are others nearly ſimilar, ſuch as the double jet d'eau, which, like the ſand-glaſs that may be claſſed with theſe, requires to be inverted as ſoon as empty, and it is eaſy to conceive a variety of ways of applying any liquid to anſwer the purpoſe of meaſuring pretty nearly a given number of hours, but we do not learn that the moſt accurate of the clepſydra is comparable to an ordinary clock, though it has been aſſerted, that Amontons conſtructed one in ſo accurate a manner, that he hoped to find it uſeful in aſcertaining the longitude at ſea by means of its accuracy; we regret that it is not in our power at preſent to procure the pamphlet in which the account of it was publiſhed. "Remarques & Experiences Phyſiques ſur la Conſtruction d'une nouvelle Clepſydre," &c. Paris. Jombert. 1695.

5. We ſhall conclude our account of theſe horological inſtruments with detailing the conſtruction and action of a clepſydra, publiſhed in the 44th volume of the Philoſophical Tranſactions by the Hon. Mr. Charles Hamilton.

A B and C D are two ſimilar oblong veſſels attached to a frame of wood, which may eaſily be conceived to ſurround figure 6, which ſhews only the interior mechaniſm; *a b* and *c d* are two columns of wood ſo floating in water, that their counterpoiſes, F and G, juſt keep their ſuperior ends equal with the ſurface of the water by means of connecting chains paſſing over the pulley *f*, and another hid by the dial plate; the former of theſe pullies, *f*, has a click which puſhes the ratchet on the barrel, *i*, when the counterpoiſe, F, falls, but ſlips eaſily over the ſlopes of the teeth when the ſaid counterpoiſe riſes; the latter pulley has alſo a ſimilar click acting in like manner, with a ſecond ratchet at the oppoſite end of the barrel, *i*, which ratchet is alſo hid in the drawing, ſo that whichever of the two counterpoiſes ſhall at any time be falling, the barrel, *i*, will move forwards in the ſame direction; and carry the minute hand along with it on the dial-plate; the hour hand goes round by means of dial-work, as in an ordinary clock or watch, where a diminution of velocity is effected by two wheels and two pinions. The action is thus produced by means of five ſyphons and two balances.

The water enters with an unvaried influx, drawn from a reſervoir, by a ſyphon of ſmall bore, the longer leg of which is ſeen at J, into the middle of what may be called a horizontal trough, ſupported like a balance by a fulcrum at K, in ſuch a manner, that either end of the balance may be elevated accordingly as the long veſſels A B and C D require to be alternately filled; near the top of each of theſe veſſels is inſerted a long ſyphon or tantalus, *l* and *m*, the lower legs of which reach down to two ſmall cylindrical veſſels, *n* and *o*, which are poiſed by another balance at the fulcrum *p*; theſe cylindrical veſſels have, in like manner, each a ſmall ſyphon, *q* and *r*; laſtly, a ſilken thread tied to the upper end of the cylinder, *n*, is carried up round a ſmall pulley faſt to the frame at *s*, and is faſtened to the end of the trough under it, and a ſimilar thread is faſtened in like manner to the cylinder *o*, and end of the trough under the ſmall pulley *t*. Now it is eaſy to conceive, that when the veſſel, A B, is filled to nearly the head of the tantalus *l*, the bore of which is larger than of the feeding ſyphon J, the water will be diſcharged into the cylindrical vaſe *n*, which conſequently will preponderate, and by means of the ſilken chord elevate the end of the trough higher than the horizontal line, and make its oppoſite end under the ſmall pulley, *t*, to be depreſſed, which will therefore conduct the water into the other long veſſel C D; during this action the counterpoiſe, F, riſes, and its pulley *f*, produces no effect on the ratchet by reaſon of the click, *h*, ſliding over the ſloping ſides of its teeth, but the counterpoiſe, G, falls, and the click of its pulley (not ſeen) puſhes the ſecond ratchet forwards in the direction of the figures of the face i [illegible] &c.

When C D is nearly full, the long ſyphon, *m*, begins to diſcharge its water; makes the cylindrical vaſe, *o*, preponderate, and again elevates by means of its ſilken ſtring the end of the trough under the ſmall pulley *t*, and depreſſes the oppoſite end to fill the veſſel, A B, again, during which time the click, *h*, of the pulley, *f*, acts with its ratchet; and thus the alternate increaſe and decreaſe of the water in the two veſſels are continued without interruption, ſo long as the feeding ſyphon continues to ſupply a ſufficient quantity of pure water. We think, however, that the mechaniſm is nearly as complex as that of a clock itſelf, and conſequently ſhould prefer a water-clock, ſuch as that made by Perrault in the year 1699, where a pendulum is uſed as the regulator, and water only as the firſt mover. For the account, ſee "Machines Approuvées," tome i. p. 39.

The ſame Perrault alſo made a water-clock with a balance and ſtriking part, an account of which is given in the volume of "Machines Approuvées," which we have juſt referred to; and in the ſeventh volume of the ſame work, is a deſcription of a regulator going by water, invented by Peronnier, and improved by Le Roy, the ſon, in 1746. (See page [illegible].)

Clepsydra is alſo uſed for an hour-glaſs of ſand.

Clepsydra is alſo applied to a chemical veſſel perforated in the ſame manner.

CLERAC, in *Geography*. See Clairac.

CLERC, John Le, in *Biography*, an eminent ſcholar and critic, was born at Geneva in the month of March 1657. He was placed at a grammar ſchool when only eight years old, and ſoon diſtinguiſhed himſelf by his abilities and by his cloſe application to his ſtudies; he attracted particular notice by the ſtrength of his memory, and his great facility in Latin poetical compoſition. His talent for poetry he did not however cultivate much beyond the compoſition of ſchool exerciſes. He devoted while young a very large ſhare of attention to the principal writers of Greece and Rome, which he read with much care and critical obſervation. When ſixteen years old he ſtudied philoſophy, natural and moral, under Chouet, who was profeſſor of philoſophy at Geneva, and taught the ſyſtem of Des Cartes. After remaining under the tuition of this maſter for two years he devoted a year to the ſtudy of the Hebrew language, under the inſtruction of the reverend James Gallatin, his maternal uncle. His fondneſs for books kept pace with his improving capacity for reading them with advantage; and he ſeldom ſuffered any to eſcape peruſal that promiſed to repay his time and labour. His diligence and aſſiduity in this particular, at this period, prepared the way for that laborious application and various and extenſive reading which afterwards ſo remarkably diſtinguiſhed him in the annals of literature. At the age of nineteen he entered on a courſe of theological ſtudies, which he continued for two years, under Meſtrezat, Turretin, and Tronchin. He read much on the controverſies then agitated in that part of Europe, and carefully ſtudied the ſcriptures in the original languages, with the aſſiſtance of the beſt commentators then extant, among whom Grotius held a pre-eminent rank. Having loſt his father in 1676 he became deſirous of viſiting France, and accordingly in 1678 he went to Grenoble and there undertook the education of a ſon of M. Saraſin de la Pierre. Here he became acquainted with father Lamy the learned author of the "Apparatus Rituus," and other works of erudition, who was prieſt of the oratory. By the end of the year he returned to Geneva, where he was ordained, after having paſſed the cuſtomary examinations with great applauſe. Not having attached himſelf to any church, he availed himſelf of his liberty to reviſit Grenoble, and thence in 1680 went to Saumur. The works of Curcellæus having been

been read by him during his first residence at Grenoble, he now availed himself of an opportunity to peruse attentively the writings of Episcopius, which confirmed him in a theological system very different from that imposed upon the belief of candidates for the ministry in his native country. He here read also the Old Testament in the Polyglot Bible, making copious notes as he proceeded, which laid the foundation of the biblical annotations which he afterwards prosecuted with so much success. The change in his sentiments having determined him to quit Geneva altogether, he returned in the autumn of 1681 from Saumur to Grenoble; the following year visited Paris, and thence proceeded to London, where he arrived in the spring of 1682. One object he had in view in visiting England was to acquire a sufficient knowledge of the language to introduce him to an acquaintance with the literature of the country, which, with his usual facility, he soon accomplished. During his residence in London he preached frequently at the Walloon church, in French, and for six months regularly served the Savoy on Sundays. As the climate of England disagreed with his constitution, he passed over to Holland in 1683 with the celebrated apostate Italian monk Gregorio Leti, whose daughter he afterwards married. He took an early opportunity to pay his respects to Limborch at Amsterdam, who gave him the information he sought respecting the principles and the condition of the Remonstrants, with whom he was greatly disposed to unite. Overcome by the importunities of his family he once more visited Geneva, but on account of his religious opinions, and the freedom with which he avowed and defended them, he returned again in the course of the same year. He now resolved to make Holland his permanent residence, and associated with the Remonstrants, occasionally officiating at their churches; but his popularity exciting the jealousy of some of the Walloon ministers, they procured an order from the magistrates to forbid him any more to preach. In the following year, however, 1684, he preached before a synod of the Remonstrants at Rotterdam, and was by them appointed professor of Hebrew, Belles Lettres, and Philosophy to their college at Amsterdam, a situation which he continued to fill until incapacitated for the discharge of its arduous duties by the malady which led to his dissolution. In 1691 he married the daughter of Gregorio Leti, as noticed above, by whom he had four children, who all died in infancy. The subsequent years of his life exhibit a wonderful picture of laborious application and unabating industry, devoted to literary pursuits, which is abundantly exemplified in the number of his publications, and the depth and variety of erudition displayed in them. We shall subjoin a brief account of such of them as are most entitled to notice. His first publication appeared anonymously at Saumur in 1679, under the title of "Liberii de Sancto Amore Epistolæ Theologicæ," in which he advocated the cause of religious toleration and freedom of inquiry, and maintained some opinions respecting the doctrine of the Trinity, and other articles of faith, which must have been deemed highly heretical by the majority of divines in that age. In 1685 he published his "Sentimens de quelques Theologiens de Hollande sur l'Histoire critique du Vieux Testament, composée par M. Rich. Simon." In this work Le Clerc delivers some very free thoughts respecting the scriptures, avowing his opinion that the Pentateuch was not written by Moses, but compiled from a variety of more ancient writings, and combating the commonly received notion of the inspiration of the sacred writers as unfounded and erroneous. The freedom of his remarks having excited much prejudice against him, and given rise to misrepresentation, he published a defence of it in 1686, in which he explains himself and states his sentiments in the most clear and explicit language. This year formed a remarkable æra in his life by the commencement of his "Bibliothéques," a series of papers comprising critical analyses and reviews of the most remarkable publications of the time, interspersed with a variety of original essays and disquisitions on such topics as excited the chief attention of literary men. The first which appeared was the "Bibliothéque Universelle et Historique." It was continued to the year 1693, and completed in 26 small volumes closely printed. In this work Le Clerc was considerably indebted to the labours of M. de la Crose, and M. Bernard, who supplied him with a considerable proportion of the papers. "Le Bibliothéque Choisie" followed in 1703, and was published at intervals until the year 1713, when it was concluded in 28 volumes, corresponding in size to the former work. To this succeeded "Bibliothéque Ancienne et Moderne," which was published from 1714 to 1727 in 29 similar volumes. These works contain a great mass of very valuable materials, of critical disquisitions and bibliographical notices and memoirs, and well deserve a place in the library of every literary man. The public are indebted to them for the documents from which Dr. Jortin principally composed his life of Erasmus. In 1690 Le Clerc published a letter to Mr. Jurieu on his treatment of Episcopius in his "Picture of Socinianism," which is a species of apology for that learned divine. Two years afterwards he published his "Logica, seu Ars Ratiocinandi" and his "Ontologia et Pneumatologia"; to these he added in 1695 his "Natural Philosophy," when he published them in an uniform edition in four volumes octavo under the general title of "Opera Philosophica." This publication has been well received, and gone through five editions. In 1693 appeared his version of the book of Genesis with critical notes, which was followed in 1696 by the other books of the Pentateuch. These were afterwards enlarged by additional notes, and in the year 1735 reached a fourth edition in folio. His "Ars Critica," first appeared in 1697, in 3 volumes 12mo. and was reprinted in the same form in 1712, and 1730. This is a most useful and valuable publication to all who wish to study ancient writings with critical accuracy and profit. He published in 1695, and again in 1714 "La Vie de Cardinal du Richelieu;" and in 1696 an excellent work in octavo under the title of "Traité de l'Incredulité," designed chiefly to expose the folly of infidelity; it was reprinted in 1714. In 1698 he printed a compendium of Universal History in Latin, in one volume octavo; the same year produced his valuable translation into Latin of the New Testament, with Hammond's Annotations, in two volumes in folio. He enriched his edition with a great number of additional critical and explanatory notes. "Parrhasiana," ou Pensées diverses sur de Matieres de Critique, d'Histoire, de Morale, et de Politique," appeared anonymously in one volume in 1699, and again in two volumes in 1702. Although interspersed with many good remarks, this has been regarded as a very hasty and incorrect performance. In 1699 he published also his "Harmonia Evangelica," in Greek and Latin, with several notes and dissertations, which drew upon him the charge of favouring the opinions of Socinus. This was followed in 1703 by a translation of the New Testament into French, in two volumes 4to. with notes, which again exposed him to the attacks of the Catholic and Calvinistic clergy. In 1708 he proceeded with his Latin version of the Old Testament, and printed the Historical Books from Joshua to Esther. "Historia Literaria II. primorum a Christo sæculorum," published in 4to. 1716, and "Histoire de Provinces Unies des Pays Bas," in three volumes in folio,

from

from 1560 to 1728, the firſt volume of which appeared in 1723, and the others in 1728, are the laſt we ſhall mention of the original works of Le Clerc. But beſides his own writings, he publiſhed ſeveral other works in the capacity of editor, many of them of conſiderable ſize and extent. Among the principal of them may be mentioned Cotelerius's "Patres Apoſtolici," two volumes folio; an edition of Moreri's Dictionary, in four volumes folio; the works of Eraſmus in 10 volumes folio, 1707; "Grotius de Veritate Relig. Chriſti," which he accompanied with ſome valuable notes; the fragments of Menander and Philemon, which had to ſubmit to the formidable ordeal of Bentley; "Livii Hiſt." in 10 volumes, in octavo, 1710; and "Æſchinis Dial. III." Gr. & Latin, 8vo. 1711. This catalogue might eaſily be ſwelled out to greater length; we ſhall, however, cloſe it here. The liſt we have given will be read with aſtoniſhment, as preſenting ſuch an example of literary induſtry as occurs hardly once in an age. Le Clerc continued this laborious courſe of writing, connected alſo with regular attention to the duties of his office as a tutor, until the year 1728, when a paralytic attack ſuſpended his purſuits, by materially impairing his intellectual powers. In 1732 a ſecond attack deprived him of ſpeech and reduced him to a ſtate little better than idiocy, in which he continued to the time of his death, which took place in 1736, in the 79th year of his age. Moreri. Gen. Dict. Gen. Biog.

Clerc, Gabriel, Le, phyſician in ordinary to Lewis XIV. and author of ſeveral eſteemed medical works, publiſhed in 1684, in 12mo., "L'Ecole du Chirurgien;" and, in 1694, "La Chirurgie complette," which was dedicated to M. Fagon. This has been many times reprinted, and is an excellent manual of the art. It contains, in the opinion of Boerhaave and Haller, the completeſt and moſt correct anatomy of the bones that had at that time been publiſhed. He alſo publiſhed, in 1700, "Appareil commode de jeunes Chirurgiens, Paris, avec Figures," 12mo.; and the following year, "Catalogue des Drogues," alſo 12mo. "La Medicine aiſee, contenant pluſieurs Remedes faciles et experimentes pour toutes Sortes de Maladies," 2 vols. 12mo. This has alſo been ſeveral times reprinted. Boerhaave Meth. Studii. Haller Bib. Med.

Clerc, Nicholas, phyſician to the duke of Orleans, which poſt he quitted, on being invited to take the place of inſpector of the hoſpital at Moſcow, where he reſided ſeveral years, and was in great eſtimation. In 1754 he was elected member of the Imperial Academy at Peterſburg, and about the ſame time honorary member of the Academy of Belles Lettres and Arts at Rouen. His works are "Medicus veri Amator ad Apollineæ Artis Alumnos," Moſchæ, 1764, 8vo.; containing a valuable collection of obſervations on epidemical diſeaſes, particularly on the epidemic that raged in the greater part of the Ruſſian empire in the year 1760. "Eſſai ſur les Maladies contagieuſes du Betail, avec les moyens de les prevenir, et d'y remedier efficacement," Paris, 1766, 12mo. The only efficacious remedy was found to be ſeparating and killing ſuch animals as were perceived to have taken the infection. "Hiſtoire Naturelle de l'Homme conſideré dans l'Etat de Maladie, ou la Medicine rapellée a ſa premiere Simplicité," Paris, 1767. His next and laſt work, on contagion, was printed, in 1771, at Peterſburg, ſoon after which he quitted Ruſſia, and retired to Beſançon, where he continued to the time of his death, which happened two or three years after. Eloy. Dict. Hiſt.

Clerc, John Le, a painter and engraver who was born at Nancy, in Lorraine, in 1587; he ſtudied, however, many years in Italy, under the tuition of Carlo Saraceno; and imitated the ſtyle of his maſter with wonderful addreſs.

He made ſeveral excellent etchings from the pictures of Saraceno, and other maſters; and died at the place of his nativity in the year 1633. Felibien. Strutt. Pilkington.

Clerc, Sebastien Le, an artiſt of very conſiderable reputation and ability; well known by the prodigious number of prints (chiefly of ſmall figures), which he etched from his own deſigns. He was born at Metz, in Lorraine, in the year 1637, and was probably of the ſame family with John Le Clerc; it is ſaid that he learned the firſt principles of drawing from his father. His firſt prints were executed entirely with the graver; the earlieſt, a head of Chriſt, is dated 1655. Upon his arrival at Paris, he was much encouraged by Le Brun, and ſometime afterwards obtained a penſion from the king, and an apartment in the Gobelins; in addition to which he received the honour of knigthood from pope Clement XI. He was a member of the Academy of Painters at Paris, and there died, at the age of 77, in the year 1714.

Le Clerc had great fertility of invention, and deſigned all kinds of ſubjects, whether of hiſtory, landſcape, or animals, with equal ſpirit and facility. His manner of etching is neat and at the ſame time free, and often bears great reſemblance to the ſtyle of Callot. The number of the plates which he executed is ſaid to exceed three thouſand. Charles Ant. de Jombert has publiſhed a catalogue of them, together with his life. Strutt. Heinecken.

Clerc, Sebastien Le, ſon of of the preceding artiſt, was born in the year 1677. He ſtudied hiſtorical painting under Bon Boulogne, and became a painter of ſome note, if we can judge from the number of prints engraved from his works. There is an altar picture by him at the abbey-church at Paris, repreſenting the death of Ananias. He was made a member of the Royal Academy of Paris, in 1704, and died, aged 86, in the year 1763.

Heinecken, in his Dictionary, mentions ſeveral other inferior artiſts of the name of Le Clerc. Heinecken. M. Papillon de la Ferté.

CLERCK, Charles, a learned man, and member of the Academy of Sciences, at Upſal, who publiſhed "Icones Inſectorum variorum, &c.". Holmiae, 1750, Gr. in 4to. with 55 plates. Not having been able to find a perſon who could colour theſe inſects to his ſatisfaction, he determined to undertake the laborious taſk himſelf; but he had ſcarcely coloured ten copies of his work when he died. Heinecken.

CLE'RES, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of Rouen. The place contains 455, and the canton 11,123 inhabitants: the territory includes $167\frac{1}{2}$ kilimetres and 33 communes.

CLEREVAUX, a town of France, in the department of the Aveiron, and diſtrict of Rhodez, or Rodés, 8 miles N.W. of it.

CLERFF. See Clervaux.

CLERGOUX, a town of France, in the department of the Correze, and diſtrict of Tulles, 6 miles N.E. of it.

CLERGY, Clerus, the aſſembly or body of clerks, or eccleſiaſtics; in contradiſtinction to the laity. This diſtinction of the whole Chriſtian commonwealth into clergy and laity, which gradually became univerſal, took its riſe among thoſe paſtors, who, at an early period, took care to improve the reſpect of the lower ranks, by widening the diſtance between their own order and the condition of their Chriſtian brethren. Although it had been unknown among the Greeks and Romans, it was familiar to many nations of antiquity; and

and the prieſts of India, of Perſia, of Aſſyria, of Judæa, of Ethiopia, of Egypt, and of Gaul, derived, or profeſſed to derive from a celeſtial origin, the temporal power and poſſeſſions which they had acquired. In the Chriſtian world it originated from the circumſtance above mentioned, and ſeems to have kept pace with the progreſs of eccleſiaſtical authority. Some have thought that they can diſcover traces of this diſtinction in a very early age of the Chriſtian church, and that it is ſanctioned by the authority of ſcripture. Others conceive that it had its riſe at a later period, when the deſire of ſpiritual and ſecular pre-eminence and correſponding dominion had perverted the minds of the profeſſors and teachers of Chriſtianity, and when the intereſt of the church was interwoven with that of the ſtate. The terms expreſſing this diſtinction, are derived from two Greek words, κληρος, lot or inheritance, and λαος, people; and this diſtinction of *clerus* and *laicus*, it is ſaid, was eſtabliſhed before the time of Tertullian, towards the cloſe of the ſecond century. The diſtinction itſelf was intended, as ſome have ſaid, to ſuggeſt, that the former, that is, the paſtors or clergy, for they appropriated the term κληρος to themſelves, were ſelected and contradiſtinguiſhed from the multitude, as being, in the preſent world, by way of eminence, God's "peculium", or ſpecial inheritance. In ſupport of this claim they allege, that God is, in the Old Teſtament, ſaid to be the inheritance of the Levites, becauſe a determinate ſhare of the ſacrifices and offerings made to God, was in part to ſerve them inſtead of an eſtate in land, ſuch as was given to each of the other tribes. But it has been argued, on the other hand, that the tribe of Levi is no where called God's inheritance, though that expreſſion is repeatedly uſed, with reſpect to the whole nation. Concerning the whole nation of Iſrael, Moſes, who was himſelf a Levite, ſays, in an addreſs to God, (Deut. ix. 29.) "They are thy people, and thine inheritance, which thou broughteſt out by thy mighty power." The words in the Septuagint, deſerve our particular attention. Ουτοι λαος σου και κληρος σου ὃς εξηγαγες εκ γης Αιγυπτου εν τη ισχυι σου τη μεγαλη. The ſame perſons are, in the ſame ſentence, declared to be both the λαος and the κληρος. What, ſays the canoniſt, at once laymen and clergy? That is certainly abſurd; the characters are incompatible; yet it did not then appear ſo to Moſes. Nor would it be thought reaſonable or juſt, that what was allowed to be the privilege and the glory of every Iſraelite, under the more ſervile eſtabliſhment of Moſes, ſhould, under the more liberal diſpenſation of the goſpel, be diſclaimed by all thoſe diſciples of Jeſus, who have not been admitted into the ſacred order, which they, for this reaſon, have called clerical. As to the uſe of the term in the New Teſtament, one paſſage, as the perſons to whom we now refer argue, and only one, occurs, in which it is applied to perſons. (See 1 Peter, v. 3.) The words in the original are, μηδ' ὡς κυριευοντες των κληρων, αλλα τυποι γινομενοι του ποιμνιου; thus rendered in our verſion, "Neither as being lords over God's heritage, but being enſamples to the flock." They are part of a charge given to the preſbyters, or paſtors, relating to their care of the people committed to them, who are called God's flock, which they are commanded to feed, of which they are to take the overſight, not the maſtery, and to which they are to ſerve as patterns. The ſame perſons, therefore, who both in this and in the preceding verſe, are ſtyled ποιμνιον, the flock, under the direction of God's miniſters, the ſhepherds, are alſo called κληροι, his inheritance, over whom their paſtors are commanded not to domineer. The diſtinction above-mentioned, it is ſaid, ſtands in direct contradiction both to the letter and to the ſenſe of the unerring ſtandard of ſcripture. Some expoſitors, however, render the term κληροι, in this paſſage, the church's poſſeſſions; but this explication, as others ſay, ill ſuits the context, and annihilates the contraſt between an imperious manner and an engaging pattern, and ſuppoſes an awkward ellipſis in the words themſelves. Beſides, it is aſked, what were the church's poſſeſſions in thoſe days? Was ſhe ſo early veſted with lands and hereditaments, for it is to ſuch only that the term κληρος, when denoting property or poſſeſſion, is applied? Or, have thoſe interpreters been dreaming of the truly golden age of pope Gregory VII., when the patrimonies of ſome metropolitical and patriarchal ſees were indeed like dukedoms and principalities, and the grand hierarch himſelf could diſpoſe of kingdoms and empires? In the apoſtolic times, on the contrary, the church's patrimony conſiſted moſtly, as we may ſay, in perſecution and calumny, hatred and deriſion, agreeably to the prediction of our Lord. Some have aſcribed the origin of the diſtinction we are now conſidering, to Clemens Romanus, who, in his epiſtle to the Corinthians, contradiſtinguiſhes λαικοι (the laics), among the Jews, from the high-prieſt, the prieſts, and the Levites. This, however, is introduced by him when ſpeaking of the Jewiſh prieſthood, and not of the Chriſtian miniſtry; nor does it ſtand in oppoſition to any one general term, ſuch as κληρος, or κληρικοι; but after mentioning theſe different orders, he uſes the term λαικοι, to include, under one comprehenſive name, all that were not ſpecially compriſed under any of the former; and, in this reſpect, it exactly correſponds to the application ſometimes made of the Latin word "popularis." Accordingly it may, with equal propriety, be contraſted with men in office of any kind whatever. Thus, in ſpeaking of civil government, it may be oppoſed to αρχοντες, to denote the people as diſtinguiſhed from the magiſtrates; or, in ſpeaking of an army, to στρατηγοι, to denote the ſoldiers as diſtinguiſhed from the commanders or officers. It is further added, that the way in which Clement employs the term does not imply, that he conſidered it as in itſelf excluſive of the prieſthood and Levitical tribe, to which the term λαικοι is oppoſed in that paſſage. They are here indeed excluded, becauſe ſeparately named, but not from the import of the word. Thus in Acts xv. 32, three orders are plainly mentioned and diſtinguiſhed, apoſtles or extraordinary miniſters, elders or fixed paſtors, and the church or chriſtian people. Does this mode of expreſſion imply, that the name church does not properly comprehend the paſtors as well as the people. The import of the expreſſion ſeems to be no more than this. "The apoſtles and elders, with all the Chriſtian brethren, who come not under either of theſe denominations." Thus alſo, in the paſſage cited from the epiſtle of Peter, where the πρεσβυτεροι are oppoſed to the κληροι, not as though the former conſtituted no part of God's heritage, or in modern phraſe, the clergy; they only do not conſtitute that part, of which they are here commanded to take the charge. In like manner Clement's mention of λαικοι, after ſpeaking of the ſeveral orders of the Jewiſh prieſthood, imports neither more nor leſs than if he had ſaid, "And all the Jewiſh people."

The diſtinction of the whole church into clergy and laity, whenſoever it originated, was extended much farther than the original intention of thoſe who adopted it. In the time of Cyprian, about the middle of the third century, we find, that, in general, all things relating to the government and policy of the church were performed by the joint conſent and adminiſtration of the clergy and laity. Thus Cyprian ſays (Epiſt. 6. § 5. cited by the author of the Enquiry into the Conſtitution, &c. of the Primitive Church, p. 106.), "he did nothing without the knowledge and conſent of his people."

people." Again (Epist. 55. § 21.), "when any letters came from foreign churches, they were received and read before the whole church, and (Epist. 58. § 2.) the whole church agreed upon common letters to be sent to other churches." In later ages, after the church had been in some degree incorporated with the state, or an alliance had been formed between them, with a view to their mutual advantage and support, the distinction of clergy and laity became an object of much greater importance; and it has been said, that the former availed themselves of it, without always consulting the benefit of the latter. Instances to this purpose might easily be adduced from the church of Rome, in the period of its full splendour and power. The laity were not always treated with due attention and respect by those of the other denomination. The schoolmen, and they belonged to the clerical body, thought it was doing the laymen too much honour to derive the name from λαος, *populus*. It suited their notions better to deduce it from λααs, *lapis*, *a stone*. The following specimen of the mode of reasoning adopted by some celebrated doctors, and cited by Altensaig in his "Lexicon Theologicum," may possibly amuse some of our readers. "Capitur clericus pro viro docto, scientifico, perito, scientia pleno, repleto et experto. E contra, laicus capitur pro viro indocto, imperito, insipiente, et lapideo. Unde laicus dicetur a λααs Græcè, quod est lapis Latinè. Et sic omnis clericus, in quantum clericus, est laudabilis; laicus vero, in quantum laicus, est vituperandus. Clerici quoque a toto genere de jure proponuntur, et debent præponi laicis." Cardinal Bona also delivers his sentiments in relation to the care that ought to be taken by the clergy, that laymen may not be allowed to do themselves harm by studying the profounder parts of scripture, which their stupidity is utterly incapable of comprehending: and though he does not absolutely prohibit their reading some of the plainer books of scripture, he indulges them more freely in the use of books containing the histories, lives, and legends of the saints, and holy meditations. See on this subject Campbell's Ecclesiastical History, vol. i.

In more modern times, and more especially in countries where the reformation has contributed to enlighten the minds and to meliorate the dispositions both of the clergy and the laity, the distinction that still subsists, for the convenient arrangement and distribution of the people, is not likely to produce any of the disadvantages that resulted from it in the darker ages.

The clergy in the first century were distinguished by the title of presbyters or bishops; and some maintain that they are of equal rank and authority. But towards the close of the second century, a notion prevailing, that the ministers of the Christian church succeeded to the character, rights, and privileges of the Jewish priesthood, this produced a subordination of rank among them. The bishops assumed a rank and character similar to those of the Jewish high-priest, the presbyters represented the priests, and the deacons the Levites. This distinction was still farther promoted towards the end of the third century, and a new set of ecclesiastical officers was established, such as sub-deacons, acolythi, door-keepers, readers, exorcists, &c. The powers of the clergy were considerably extended under the patronage of Constantine the Great, about the close of the fourth century.

The clergy were anciently divided into three orders; *viz.* priests, deacons, and inferior clerks; and each order had its chief: the arch-priest was the head of the first order, the arch-deacon of the second, and the dean of the third.

Under the name of clergy, were also formerly comprised all the officers of justice; as being supposed to be men of letters.

In the Romish church there are two kinds of clergy; the one *regular*, comprehending all the religious of both sexes, as abbots, monks, priors, &c.; the other *secular*, comprehending all the ecclesiastics that do not make the monastic vows. Among the reformed, there are none but those of the latter. The Roman clergy forms a monarchical state, under the pope, as its supreme head.

In England, the term clergy comprehends all persons in holy orders, and also in ecclesiastical offices; *viz.* archbishops, bishops, deans and chapters, arch-deacons, rural deans, parsons, who are either rectors or vicars, and curates; to which number we may also add, parish clerks, who formerly frequently were, and still sometimes are, in orders. See each of the articles above enumerated.

This venerable body of men, being separated and set apart from the rest of the people, in order to attend the more closely to the service of Almighty God, have several privileges allowed them by our municipal laws, and those privileges were formerly much greater than they have been since the reformation, at which time they were abridged on account of the ill use which the popish clergy had endeavoured to make of them. For as the laws exempted them from almost every personal duty, they attempted to obtain for themselves a total exemption from every secular tie; and as it has happened in other cases, by extending their claims too far, they either lost or ceased to enjoy those liberties which of right belonged to them. The personal exemptions, however, for the most part are still continued. A clergyman cannot be compelled to serve on a jury, nor to appear at a court-leet or view of frank-pledge; which almost every other person is obliged to do. 2 Inst 4. But if a layman is summoned on a jury, and before the trial takes orders, he shall, notwithstanding, appear and be sworn. 4 Leon. Neither can he be chosen to any temporal office, as bailiff, reeve, constable, or the like, in regard of his own continual attendance on the sacred functions. Finch. L. 88. During his attendance on divine service, he is privileged from arrests in civil suits. Stat. 50 Edw. III. c. 5. 1 Ric. II. c. 26. In cases also of felony, a clerk in orders shall have the benefit of his clergy, without being branded in the hand; and may likewise have it more than once; in both which particulars he is distinguished from a layman. 2 Inst. 637. Stat. 4 Hen. VII. c. 13. and 1 Edw. VI. c. 12. As they have their peculiar privileges, they have also their disabilities, on account of their spiritual avocations. Clergymen, as some have maintained, are incapable of sitting in the House of Commons, (see PARLIAMENT); and by stat. 21 Hen. VIII. c. 13. they are not (in general) allowed to take any lands or tenements to farm, on pain of 10*l.* per month, and total avoidance of the lease; unless where they have not sufficient glebe; and the land is taken for the necessary expences of their household. Stat. §. 8.; nor, on the like penalty, are they allowed to keep any tan-house or brew-house; nor to engage in any manner of trade, nor to sell any merchandize, under forfeiture of the treble value, which prohibition is consonant to the canon law. By the statute called "Articuli Cleri," 9 Ed. II. st. 1. c. 3., if any person lay violent hands on a clerk, the amends for the peace broken (1) shall be before the king (that is by indictment), and the assailant may (2) also be sued before the bishop, that excommunication or bodily penance may be imposed; which if the offender will redeem by money, it may (3) be sued for before the bishop. See ARTICLES *of the Clergy* and BATTERY.

Though the clergy formerly claimed an exemption from all secular jurisdiction, yet Matt. Paris tells us, that William the Conqueror subjected the bishops and abbeys who held *per baronium*, and who, till then, had been exempt from all secular service; and ordered they should be no longer free

from

from military services. To this purpose he prescribed arbitrarily what number of soldiers every abbey and bishopric should provide, to serve him and his successors in time of war, and laid up the registers of ecclesiastical servitude in his treasury. But, in effect, the clergy were not exempt from all secular service till then; as being bound by the laws of king Edgar to obey the secular magistrate in some things; *viz.* upon an expedition to the wars, and in contributing to the building and repairing of bridges, &c. See TRINODA *necessitas.*

The privileges of the English clergy, confirmed to them by Magna Charta, and by the ancient statutes, are very considerable: their goods are to pay no toll in fairs or markets; they are exempt from all offices but their own; from the king's carriages, posts, &c. from appearing at sheriffs' tourns or frank-pledges; and are not to be fined or amerced, according to their spiritual, but their temporal means. A clergyman acknowledging a statute, his body is not to be imprisoned; if he be convicted of a crime for which the benefit of clergy is allowed, he shall not, as we have before observed, be burnt in the hand. See *Benefit of* CLERGY.

The clergy, by common law, are not to be burdened in the general charges with the laity; nor to be troubled or incumbered, unless expressly named, and charged by the statute; for general words do not affect them. Thus, if a hundred be sued for a robbery, the minister shall not contribute; though the words are *gentes demorantes:* neither are they assessed to the highway, to the watch, &c. But these privileges are in a great measure lost; the clergy being included under general words in later statutes: so that they are liable to all public charges imposed by act of parliament, where they are not particularly excepted. Besides the exemptions and privileges above stated, their bodies are not to be taken on statutes-merchant, or staple, &c.; for the writ to take the body of the conusor is "Si laicus sit;" and if the sheriff, or any other officer, arrest a clergyman upon any such process, it is said that an action of false imprisonment lies against him that does it; or the clergyman arrested may have a "superfedeas" out of Chancery. 2 Inst. 4. In action of trespass, account, &c. against a person in holy orders, wherein process of "capias" lies, if the sheriff return that the defendant is "Clericus beneficiatus nullum habens laicum feodum ubi summoneri potest:" in this case the plaintiff cannot have a "capias" to arrest his body; but a writ should be addressed to the bishop, compelling him to appear: nevertheless, when execution is obtained, a sequestration of the profits of his benefice may be had.

The revenues of the clergy were anciently more considerable than at present. Ethelwolph, in 855, gave them the tythe of all goods, and the tenth of all the lands in England; free from all secular services, taxes, &c. The charter whereby this was given them, was confirmed by several of his successors; Edmund, Edgar, Ethelred, Alfred, and William the Conqueror; the last of whom, finding the bishoprics so rich, erected them all into baronies; each barony containing thirteen knights' fees at least. But since the Reformation, the bishoprics are much impaired. See BISHOP.

The revenues of the inferior clergy, in the general, are small; a third part of the best benefices being anciently, by the pope's grant, appropriated to monasteries; upon the dissolution whereof they became lay-fees. Indeed, an addition was made, 2 Anne; the whole revenue of first-fruits and tenths being then granted, to raise a fund for the augmentation of the maintenance of the poor clergy: pursuant to which, a corporation was formed, by the name of governors of the bounty of queen Anne, for the augmentation of the maintenance of the poor clergy; to whom the said revenues were conveyed in trust, &c. See AUGMENTATION. For a statement of the number and revenues of the clergy of the established churches of England and Scotland; see CHURCH *of England*, and CHURCH *of Scotland.*

CLERGY, *articles of the.* See ARTICLES.

CLERGY, *proctors of the.* See PROCTORS.

CLERGY, *Privilegium Clericale,* or *Benefit of Clergy,* denotes an ancient privilege of the church, consisting in this, that places consecrated to religious duties were exempted from criminal arrests, whence proceeded sanctuaries; and that the persons of clergymen were exempted from criminal process before the secular judges in particular cases. This, at first, was an indulgence granted by the civil government, or Christian princes, from a pious regard to the church in its infant state; but as the clergy increased in wealth, power, honour, number, and interest, that which was first obtained by favour, was afterwards claimed as an inherent, indefeasible, and *jure divino* right: and the clergy endeavoured to extend the exemption not only to almost all kinds of crimes, but to a variety of persons, besides those who were properly of their own order. In England, though this privilege was allowed in some capital cases, it was not universally admitted. The method of granting it was settled in the reign of Henry VI. which required, that the prisoner should first be arraigned, and then claim his benefit of clergy, by way of declinatory plea, or, after conviction, by way of arrest of judgment; which latter mode is most usually practised. This privilege was originally confined to those who had the *habitum & tonsuram clericalem:* but in process of time every one was accounted a clerk, and admitted to this benefit, who could read, though neither initiated in holy orders, nor trimmed with the clerical tonsure; so that, after the invention of printing, and the dissemination of learning, this became a very comprehensive test, including laymen as well as divines; and, therefore, the stat. 4 Hen. VII. cap. 13, distinguishes between lay scholars, and clerks in holy orders; and directs that the former should not claim this privilege more than once, and, in order to their being afterwards known, that they should be burnt with a hot iron in the brawn of the left thumb. This distinction between learned laymen, and real clerks in orders, was abolished, for a time, by 28 Hen. VIII. cap. 1. and 32 Hen. VIII. cap. 3, but is held (Hob. 294. 2 Hal. P. C. 375.) to have been virtually restored by 1 Ed. VI. cap. 12, in consequence of which statute, peers of the realm, and lords of parliament, having place and voice in parliament, were entitled to the benefit of their peerage, equivalent to that of clergy, for the first offence, though they could not read, and for all offences then clergyable to commoners, and also for the crimes of house-breaking, highway robbery, horse-stealing, and robbing of churches. When those, admitted to the privilege of their clergy, the laity after burning, and before it, the real clergy, were thus discharged from the sentence of the law in the king's court, they were delivered over to the ordinary for canonical purgation. But this purgation having given occasion to a scandalous prostitution of oaths, and other abuses, it became necessary, when the reformation was thoroughly established, to abolish a ceremony so vain and impious. Accordingly, it was enacted by stat. 18 Eliz. cap. 7, that all such persons, instead of being committed to the ordinary, should be delivered out of prison, provided the judge does not think fit to continue them in goal for a limited time, not exceeding a year. Further alterations were made in the law respecting this privilege, by 21 Jac. I. cap. 6, which allowed, that women convicted

convicted of ſimple larcenies under the value of 10*s.* ſhould not properly have the benefit of clergy, for they were not called upon to read; but be burned in the hand, and whipped, ſtocked, or impriſoned for any time not exceeding a year. See Branding. And a ſimilar indulgence by 3 and 4 W. and M. cap. 9, and 4 and 5 W. and M. cap. 24, was extended to all women guilty of any clergyable felony; who were allowed once to claim the benefit of the *ſtatute*, in like manner as men might claim the benefit of *clergy*, and to be diſcharged upon being burned in the hand, and impriſoned for any time not exceeding a year. The puniſhment of burning in the hand being found ineffectual, was alſo changed by ſtatute 10 and 11 W. III. c. 23, into burning in the moſt viſible part of the left cheek, neareſt the noſe; but ſuch an indelible ſtigma being found by experience to render offenders deſperate, this proviſion was repealed about ſeven years afterwards, by ſtat. 5 Ann. c. 6.; and till that period, all women, all peers of parliament, and peereſſes, and all male commoners who could read, were diſcharged in all clergyable felonies; the males abſolutely, if clerks in orders; and other commoners, both male and female, upon branding, and peers and peereſſes without branding, for the firſt offence; all, however, except peers and peereſſes, liable to impriſonment, as before mentioned; and thoſe men who could not read, if under the degree of peerage, were hanged. By 5 Anne, cap. 6, the benefit of clergy was indiſcriminately granted to all who had a right to aſk it, without the condition of reading. It was further enacted by the ſame ſtatute, that when any perſon is convicted of any theft or larceny, and burned in the hand for the ſame, according to the ancient law, he ſhall alſo, at the diſcretion of the judge, be committed to the houſe of correction, or public workhouſe, to be there kept to hard labour for any time not leſs than ſix months, and not exceeding two years; with a power of inflicting a double confinement in caſe of the party's eſcape from the firſt. Again, by 4 Geo. I. cap. 11, and 6 Geo. I. cap. 23, it is enacted, that when any perſons ſhall be convicted of larceny, either grand or petit, or any felonious ſtealing or taking of money, or goods and chattels, either from the perſon or the houſe of another, or in any other manner, and who by the law ſhall be entitled to the benefit of clergy, and liable only to the penalties of branding or whipping, the court in their diſcretion may direct ſuch offenders, inſtead of burning or whipping, to be tranſported to America, (or, by ſtat. 19 Geo. III. c. 74, to any other parts beyond the ſeas), for ſeven years; and if they return within that time, it ſhall be felony without benefit of clergy. For other particulars, ſee Branding, and Transportation.

It appears, from the above account, that the perſons to whom this privilege now extends, are clerks in orders, without branding, and of courſe without any tranſportation, fine, or whipping; lords of parliament and peers of the realm, and alſo peereſſes, for the firſt offence; and all commoners, not in orders, whether male or female, for clergyable felonies, upon being burnt in the hand, whipped, or fined, or impriſoned, at the diſcretion of the judge, in the common gaol, the houſe of correction, one of the penitentiary houſes, or in the places of labour for the benefit of ſome navigation; and in caſe of larceny, on being tranſported for ſeven years, or ſuffering the puniſhment more lately ſubſtituted in the room of tranſportation.

It is a privilege peculiar only to the clergy, that ſentence of death can never be paſſed upon them for any number of man-ſlaughters, bigamies, ſimple larcenies, or other clergyable offences; but a layman, even a peer, may be ouſted of clergy, and will be ſubject to the judgment of death, upon a ſecond conviction of a clergyable offence. Thus, if a layman has been once convicted of man-ſlaughter, upon production of the conviction, he may ſuffer death for bigamy, or any other clergyable felony; which would not therefore be a capital crime to another perſon not ſo circumſtanced.

It hath been ſaid, that Jews, and other infidels and heretics, were not capable of the benefit of clergy, till after the ſtatute 5 Ann. c. 6., as being under a legal incapacity for orders. 2 Hal. P. C. 373. 2 Hawk. P. C. 33. §. 5. Forſt. 306. But judge Blackſtone much queſtions, whether this was ever ruled for law, ſince the re-introduction of the Jews into England, in the time of Oliver Cromwell. For, if that were the caſe, the Jews are ſtill in the ſame predicament, which every day's experience will contradict; the ſtatute of queen Anne having certainly made no alteration in this reſpect; it only diſpenſing with the neceſſity of reading in thoſe perſons, who, in caſe they could read, were before the act entitled to the benefit of their clergy.

A perſon, having once had benefit of clergy, ſhall not be ouſted of his clergy, by the bare mark in his hand, or by a parol averment, without the record teſtifying it, or a tranſcript thereof, according to the following ſtatutes: 2 H.H. 373. By ſtat. 34 and 35 Hen. VIII. cap. 14. the clerk of the crown, or of the peace, or of the aſſiſe, ſhall certify a tranſcript briefly of the tenor of the indictment, outlawry, or conviction, and attainder, into the King's Bench in 40 days; and the clerk of the crown, when the judges of aſſiſe, or juſtices of the peace, write to him for the names of ſuch perſons, ſhall certify the ſame, with the cauſes of the conviction or attainder. Another method is given by the ſtat. 3 W. and M. cap. 9. §. 7.; which enacts, that the clerk of the crown, clerk of the peace, or clerk of aſſiſe, where a perſon admitted to clergy under that act ſhall be convicted, ſhall at the requeſt of the proſecutor, or any other on the king's behalf, certify a tranſcript briefly and in few words, containing the effect and tenor of the indictment and conviction, of his having the benefit of clergy, and the addition of the party, and the certainty of the felony and conviction, to the judges where ſuch perſon ſhall be indicted for any ſubſequent offence. It ſeems alſo, that if the party deny that he is the ſame perſon, iſſue muſt be joined upon it, and it muſt be found upon trial that he is the ſame perſon, before he can be ouſted of clergy. 2 H. H. 373. Againſt the defendant's prayer of clergy, the proſecutor may file a "counter-plea;" alleging ſome fact, which in law deprives the defendant of the privilege he claims. It is a good counter-plea to the prayer of clergy, that the offender is not entitled to the benefit of the ſtatute, becauſe he was before convicted of an offence, and thereupon prayed the benefit of the ſtatute, which was allowed to him; alleging the truth of the fact and praying the judgment of the court, that he may die according to law; which fact is to be tried by the record in purſuance of the ſtatute 34 and 35 Hen. VIII. c. 14. Staunf. 135. Divers other counter-pleas, by which an offender may be deprived of clergy, may alſo be framed from a conſideration of the *perſons* to whom it is allowed or denied by the common law; and of the *circumſtances* under which that allowance or denial of it has been placed by divers ſtatutes. Ib. 138. The uſe of this counter-plea has, however, long become obſolete, and out of uſe. But the daring practices of ſome money-coiners occaſioned its revival; and in 1783, on occaſion of the conviction of money-coiners, a counter-plea of record was filed on the part of the proſecution; alleging that the convicts had been before allowed

lowed the benefit of the ſtatute, &c.; and they were thereby ouſted of their clergy. Leach's Hawk. P. C. ii. c. 33. §. 19. *n.*

The privilege of clergy was not indulged at the common law, either in high treaſon, or petit larceny, or in any mere miſdemeanors; and therefore it may be laid down as a rule, that it was allowable only in petit treaſon, and in capital felonies; which, for the moſt part, became legally entitled to this indulgence by the ſtatute "de clero," 25 Edw. III. ſt. 3. c. 4., which provides, that clerks convicted for treaſons or felonies, touching other perſons than the king himſelf or his royal majeſty, ſhall have the privilege of holy church. But it was not allowed in all felonies; in ſome of which it was denied even by the common law, *viz.* "inſidiatio viarum," or lying in wait for one on the high-way; "depopulatio agrorum," or deſtroying and ravaging a country (2 Hal. P. C. 333.); and "combuſtio domorum," or arſon, that is, the burning of houſes; all which are a kind of hoſtile acts, and in ſome degree border upon treaſon. Moreover, all theſe crimes, together with petit treaſon, and many other acts of felony, are ouſted of clergy by particular acts of parliament. All the ſtatutes for excluding clergy are merely the reſtoration of the law to the ſame rigour of capital puniſhment in the firſt offence, that was exerted before the "privilegium clericale" was at all indulged; and which it ſtill exerts upon a ſecond offence in almoſt all kinds of felonies, unleſs committed by clerks in actual orders. But ſo tender is the law of inflicting capital puniſhment in the firſt inſtance for any inferior felony, that notwithſtanding by the marine law, declared in ſtatute 28 Hen. VIII. c. 15. the benefit of clergy is not allowed in any caſe whatſoever; yet, when offences are committed within the admiralty-juriſdiction, which would be clergyable if committed by land, the conſtant courſe is to acquit and diſcharge the priſoner. Moor. 756. Foſt. 288. It is not neceſſary, that the ordinary ſhould demand the benefit of the clergy for a clerk; nor is there any neceſſity that the priſoner himſelf ſhould demand it, where it ſufficiently appears to the court, that he hath a right to it, in reſpect of his being in orders, &c. In which caſe, if the priſoner does not demand it, it is left to the diſcretion of the judge, either to allow, or not allow it to him. 2 Hawk. P. C. c. 33. §. 112. Clergy may be demanded after judgment given againſt a perſon, whether of death, &c. and even under the gallows, if a proper judge be there, who has power to allow it. 2 Hawk. P. C. c. 33. §. 111.

Upon the whole we may obſerve in relation to this ſubject: 1. That in all felonies, whether newly created or by common law, clergy is now allowable, unleſs taken away by expreſs words of an act of parliament. 2 Hal. P. C. 330. 2. That, where clergy is taken away from the principal, it is not of courſe taken away from the acceſſory, unleſs he be alſo particularly included in the words of the ſtatute. 2 Hawk. P. C. 342. 3. That, when the benefit of clergy is taken away from the *offence*, (as in caſe of murder, buggery, robbery, rape, and burglary), a principal in the ſecond degree, being preſent, aiding and abetting the crime, is as well excluded from his clergy as he that is principal in the firſt degree: but, 4. That, where it is only taken away from the *perſon committing* the offence, (as in the caſe of ſtabbing, or committing larceny in a dwelling-houſe, or privately from the perſon), his aiders and abettors are not excluded; through the tenderneſs of the law, which hath determined that ſuch ſtatutes ſhall be taken literally. 1 Hal. P.C. 529. Foſter, 356, 357.

As to the conſequences to the party of allowing him this benefit of clergy, they are ſuch as affect his preſent intereſt and future credit and capacity; as having been once a felon, but now purged from that guilt by the privilege of clergy; which operates as a kind of ſtatute-pardon. It may be obſerved, 1. That, by his conviction, he forfeits all his goods to the king; which, being once veſted in the crown, ſhall not afterwards be reſtored to the offender. 2 Hal. P. C. 388. 2. That, after conviction, and till he receives the judgment of the law, by branding or ſome of its ſubſtitutes, or elſe is pardoned by the king, he is to all intents and purpoſes a felon, and ſubject to all the diſabilities and other incidents of a felon. 3 P. Wms. 487. 3. That, after burning, or its ſubſtitute, or pardon, he is diſcharged for ever of that, and all other felonies before committed, within the benefit of clergy; but not of felonies from which ſuch benefit is excluded; and this by ſtatutes 8 Eliz. c. 4. and 18 Eliz. c. 7. 4. That by the burning, or its ſubſtitute, or the pardon of it, he is reſtored to all capacities and credits, and the poſſeſſion of his lands, as if he had never been convicted. 2 Hal. P. C. 389. 5 Rep. 110. 5. That what is ſaid with regard to the advantages of commoners and laymen, ſubſequent to the burning in the hand, is equally applicable to all peers and clergymen, although never branded at all, or ſubjected to other puniſhment in its ſtead. For they have the ſame privileges, without any burning or any ſubſtitute for it, which others are entitled to after it. 2 Hal. P.C. 389, 390. Blackſt. Comm. vol. iv.

Clergy, *Corporation of the Sons of the*, a benevolent inſtitution, which ſeems to have originated in the time of the Uſurpation, when a ſermon was preached at St. Paul's, Nov. 8, 1658, to the ſons of miniſters ſolemnly aſſembled; the deſign of which was to promote charitable contributions in favour of the ſons of the clergy. Whether or not ſermons of this kind were annual before the Reſtoration, we are not able to aſcertain; however, afterwards, a charter was granted, bearing date July 1, 1678, by which a body politic and corporate was conſtituted, under the name of "The Governors of the Charity for the Relief of the poor Widows and Children of Clergymen," with licence to poſſeſs any eſtate, not exceeding the yearly value of 2000 *l.* Upon the acceſſion of a gift by Dr. Thomas Turner, amounting to about 18,000 *l.* the governors obtained, Dec. 16, 1714, an augmentation of the ſaid grant, by a licence to poſſeſs the yearly value of 3000 *l.* over and above all charges and repriſes, as alſo over and above the ſaid 2000 *l. per annum.* To promote the uſeful and laudable purpoſe of this inſtitution, a ſermon was preached at the anniverſary meeting of the ſons of clergymen in the church of St. Mary le Bow, Nov. 7, 1678, by Dr. T. Sprat, afterwards biſhop of Rocheſter, in which it appears, that thoſe ſervices had been cuſtomary before they were encouraged by a royal eſtabliſhment. Theſe ſermons continued to be preached at Bow church till the year 1697, when Dr. George Stanhope preached his ſermon for the benefit of this charity at the cathedral church of St. Paul, at which time it is ſuppoſed the thought was firſt ſuggeſted of a grand muſical performance in aid of the charity. The annual feaſt of the ſons of the clergy appears to be prior to their incorporation; for in the London Gazette of Nov. 22, 1677, the annual feaſt of the ſons of the clergy was advertiſed to be held at Merchant Taylors Hall, on Thurſday the 29th of November following. Since the year 1697, there has been conſtantly an annual ſermon, and alſo a grand muſical ſervice at the cathedral church of St. Paul, for promoting the ends of this charity. The moſt eminent divines of the church have preached on theſe occaſions, and the muſical performance has acquired celebrity from the concurrence of eminent perſons of the profeſſion. For many years paſt it has been the practice of the ſtewards of the corporation, to have at St. Paul's on the Tueſday

 preceding

preceding the day of the sermon, what is called a rehearsal of the performance, and also a collection for the charity. The corporation is under the management of a president (the archbishop of Canterbury), a vice-president, three treasurers, and a numerous court of assistants.

The society for maintaining, educating, and apprenticing poor orphan children of clergymen, was instituted in 1749, and is under the direction of a president (bishop of London), a vice president, a treasurer, and secretary.

CLERI, in *Ancient Geography* a people of Asia Minor, in the Lesser Asia, mentioned by Diodorus Siculus.

CLERICAL *Crown*. See CROWN.

CLERICAL *Title*. See TITLE.

CLERICI, TOMMASO, in *Biography*, an historical painter of Genoa. He was born in 1637, and became the disciple of Francisco Merano, called il Paggio; and, though he died of the plague in the 21st year of his age, *anno* 1657, yet the progress he had made in the art was so great, that the four altar pictures remaining of his hand, in the church and sacristy of the Nunziata del Guastato, at Genoa, have at all times been much admired. One of these represents the three archangels, Michael, Gabriel, and Raphael; the second, the Virgin Mary, with the image of St. Dominick; the third, a martyrdom of saints; and the last, a number of Franciscan friars following Christ, who is bearing his cross. Soprani. Orlandi.

CLERICI *non eligantur in officio*. See QUOD *Clerici*.

CLERICIS *regis, non-residentia pro*. See NON-*residentia*.

CLERICO *admittendo*. See ADMITTENDO *Clerico*.

CLERICO *capto per statutum mercatorum*, is a writ for the delivery of a clerk out of prison, who is imprisoned upon the breach of a statute-merchant. Reg. Orig. 147.

CLERICO *convicto commisso gaolæ in defectu ordinarii deliberando*, is a writ for the delivery of a clerk to his ordinary, that was formerly convicted of felony; by reason his ordinary did not challenge him according to the privilege of clerks. Reg. Orig. 69.

CLERICO *intra sacros ordinis constituto non eligendo in officium*, is a writ directed to the bailiffs, &c. that have thrust a bailiwick or beadleship upon one in holy orders, charging them to release him. Reg. Orig. 143.

CLERIEUX, in *Geography*, a town of France, in the department of the Drome, and district of Valence, 5 miles N.W. of Romans.

CLERINCE, a town of Poland, in the palatinate of Braclaw; 44 miles S.S.W. of Braclaw.

CLERISSEAU, CHARLES LOUIS, in *Biography*, an artist who was born at Paris 1718, and is well known by his beautiful pictures in water colours, representing the ruins and picturesque views of Italy, where he long studied. He was, upon his return, made a member of the Royal Academy at Paris, and, some time after, he received a similar honour in England, the Royal Academy of London being just then instituted.

Several prints have been engraved from his works, and, amongst others, an excellent set of thirteen large views of ancient buildings, by Domenico Cunego of Rome. Heinecken.

CLERK, DANIEL LE, a celebrated physician, and learned writer on the history and practice of medicine, was born at Geneva, Feb. the 4th, 1652. He was the son of Stephen le Clerk, professor in the Greek language, and from him received the rudiments of his knowledge, as well as his taste for research into antiquity, by which he became in time so famous. Having completed his school education, he went, in succession to Montpellier, Paris, and Valence, where he took his degree of doctor in medicine, in 1672. He now returned to Geneva, and soon found himself in considerable practice, which he attended to with zeal, until the year 1704, when, being appointed one of the members of the council of state, he entirely renounced practice, that he might have leisure to fill the honourable post to which he had been raised, and to correct and complete the various works in which he had been engaged, and which had given him a distinguished rank among the principal literary characters of his age. He died June 8th, 1728, leaving two sons, James, who had been educated to medicine, and James Theodore, who was minister of the gospel, and professor of the Oriental Languages. He had published, in conjunction with James Mangets, "Biblioth. Anatomica," 2 vols. folio, in 1685; but the work for which he is principally celebrated, is his "Histoire de la Medicine, ou l'on voit l'Origine et le Progres de cette art de Siecle, en Siecle:" A work of immense erudition, in which are depicted the opinions, or theories of medicine, which have prevailed from the earliest period to the time of Galen. The first part, which brought the history of medicine only to the time of Hippocrates, was published in one volume, 8vo. 1696. Finding this approved, he produced the work completed in one volume, 4to. in 1702. This was reprinted in 1723; and again, with additions, and much improved, in 1729. To this edition he added a plan of a continuation of the history, to the middle of the 17th century, but which his age and avocations prevented his completing. Friend, who pays the author the highest compliments on the completion of the work, which it amply deserves, is very severe in his censure of this plan. But he would surely have spared his reproof, if he had attended to the apology made by the author, who was well acquainted with its defects. Friend wrote a continuation of the history, and in so excellent a manner, as to leave little reason to regret that it had not been finished by Le Clerk. "Historia naturalis et medica latorum Lumbricorum intra Hominem et Animalia nascentium," Genevæ, 1715, 4to. which contains all that is known on the subject of those pernicious reptiles. A little before he died, he translated, Senebier says, the first "Satyr of Persius" into the French language; but this has not been printed. Haller, Bib. Med. Senebier, Histoire Literaire de Geneve.

CLERK, CLERICUS, a word formerly used to signify a learned man, or man of letters. For the etymology of the term, see CLERGY.

Thus, Pasquier observes, the officers of the counts (*comites*) were anciently created under the title of *clerks of accompts*; and secretaries of state were called *clerks of the secrets*. So, *Clericus domini regis*, in the time of Edward I. was rendered in English, the *king's secretary*, or *clerk of his council*.

The term was applied indifferently to all who made any profession of learning, or who knew how to manage the pen; though, originally, it was appropriated to ecclesiastics.

As the nobility and gentry were usually brought up to the exercise of arms; there were none but the clergy left to cultivate the sciences; hence, as the clergy alone made any profession of letters, a very learned man came to be called a *great clerk*, and a stupid ignorant man, a *bad clerk*.

Ronsard, in his old language, uses the word femininely, *clergesse*, for a learned woman. "*Mais trop plus est à craindre une feme clergesse.*"

CLERK (in general), is used as synonymous with *clergyman* for all those of the ecclesiastical state, who are in holy orders, of any degree, or kind, from the deacon, to the prelate.

Yet, in its utmost latitude, the word clerk also includes

CHANTORS,

CHANTORS, ACOLYTHI, EXORCISTÆ, and OSTIARII. The word, however, has been anciently ufed for a fecular prieft, in oppofition to a religious or regular. Paroch. Antiq. 171. The canons excommunicate all thofe who lay hands on a clerk. A council held in Africa prohibited the appointing any clerk to be a tutor, guardian, or curator, by teftament. The council of Elvira enjoins continence on all clerks, bifhops, priefts, or deacons, on pain of being ftripped of their clericature.

CLERK, *acephalous*, in the fixth century, was a name given to thofe clerks who feparated from the bifhop, and chofe not to live any longer in community with him; in contradiftinction to

CLERKS, *canonic*, who continue to live with the bifhop, according to the canons.

CLERK, in the way of trade and bufinefs, is one who exercifes any function with the pen.

The Clergy, in the early ages, engroffed almoft every kind of learning to themfelves; and they were peculiarly remarkable for their proficiency in the ftudy of the law. Thus William of Malmfbury characterifes them foon after the conqueft, "Nullus clericus nifi caufidicus." The judges, therefore, were ufually created out of the facred order; and all the inferior offices were fupplied by the lower clergy, which has occafioned their fucceffors to be denominated clerks to this day. Accordingly, this title is given to feveral officers of this kind in the royal palace, the courts of juftice, revenue, army, navy, &c. The principal of thefe are as follow:

CLERK *of the Acts*, is an officer of the navy, who receives and enters the commiffions, contracts, warrants, &c. of the lord high admiral; and regifters the acts and ordinances of the lords commiffioners of the admiralty, and commiffioners of the navy. Stat. 22 & 23 Car. II. c. 11.

CLERK *of Affidavits*, in the court of chancery, an offirec who files all affidavits made ufe of in court.

CLERK *of Affife*, is he that writeth all things judicially done by the juftices of affife, in their circuits.

This office is affociated to the judge in commiffions of affife, to take affifes, &c. He fhall not be counfel with any perfon in the circuit. Stat. 33 Hen. VIII. c. 24. § 5. He certifies the names of felons convict. See *Benefit of* CLERGY. He is punifhable for concealing, &c. any indictment, recognizance, fine, or forfeiture. See ftat. 22 & 23 Car. II. c. 22. § 9. 3 Geo. I. c. 15. §. 12. He is to take only 2*s*. for drawing an indictment, and nothing if defective. 10 & 11 W. III. c. 23. §. 7, 8. The clerk of affife is fineable for falfely recording appearances of perfons returned on a jury. 3 Geo. II. c. 25. §. 3.

CLERK of *the Bails*. See BAILS. *clerk of the*.

CLERK of *the Check* or *Cheque*. See CHECK.

CLERK *of the Clofet*, is a divine, otherwife called *confeffor to his Majefty*; whofe office is to attend at the king's right hand during divine fervice, to refolve all doubts concerning fpiritual matters, to wait on the king in his private oratory, &c.

CLERK *controller of the king's houfe*, an officer in the king's court, that hath authority to allow or difallow charges and demands of purfuivants, meffengers of the green-cloth, &c. He hath likewife the overfight of all defects and mifcarriages of any of the inferior officers; and he hath a right to fit in the counting-houfe with the fuperior officers, *viz*. the lord-fteward, treafurer, controller, and cofferer of the houfhold, for correcting any diforders. There are two officers of this kind. See ftat. 33 Hen. VIII. c. 12.

CLERK *of the Crown*, in the king's bench court, an officer whofe bufinefs is to frame, read, and record all indictments againft traitors, felons, and other offenders there arraigned or indicted of any public crime.

When divers perfons are jointly indicted, the clerk of the crown fhall take for them all but one fee, *viz* 2*s*. Stat. 2 Hen. IV. c. 10. He is otherwife denominated *clerk of the crown-office*, and exhibits informations, by order of the court, for divers offences. See INFORMATION.

CLERK *of the Crown*, in chancery, is an officer, who, by himfelf, or deputy, is continually to attend the lord-chancellor, or lord-keeper, to write or propofe fpecial matters of ftate by commiffion, or the like, either immediately from his majefty's orders, or by order of his council; as well ordinary as extraordinary, *viz*. commiffions of lieutenancy, of juftices of affife, oyer and terminer, gaol-delivery, and of the peace, with their writs of affociation, &c. All general pardons, upon grants of them at the king's coronation, or in parliament, where he fits in the lords' houfe in parliament time; the writs of parliament, with the names of the knights, citizens, and burgeffes, are alfo returned into his office, and filed; befides which, he has the making of fpecial pardons, and writs of execution upon bonds of ftatute ftaple forfeited, which was annexed to this office in the reign of queen Mary, in confideration of his chargeable attendance.

CLERK *of the Declarations*, an officer in the court of king's bench, that files all declarations in caufes there depending, after they are engroffed, &c.

CLERK *of the Deliveries*, is an officer in the Tower of London, who takes indentures for all ftores iffued thence.

CLERK *of the Errors*, in the court of common pleas, tranfcribes, and certifies into the king's bench, the tenor of the records of the caufe, or action, upon which the writ of error, made by the curfitor, is brought there, to be heard and determined.

CLERK *of the Errors*, in the king's bench, tranfcribes and certifies the records of fuch caufes in that court into the exchequer; if the caufe, or action, is by bill: if by original, the lord chief juftice certifies the record into the houfe of peers in parliament, by taking the tranfcript from the clerk of errors, and delivering it to the lord chancellor, there to be determined, according to the ftats. 27 Eliz. c. 8. and 31 Eliz. c. 1.

CLERK *of the Errors*, in the exchequer, tranfcribes the records certified thither out of the king's bench; and prepares them for judgment in the court of exchequer, to be given by the juftices of the common-pleas, and barons, there. Stats. 16 Car. II. c. 2. 20 Car. II. c. 4.

CLERK *of the Effoins*, in the court of common pleas, keeps the effoin-rolls, or enters effoins. He alfo provides parchment, cuts it into rolls, marks the number on them; delivers out all the rolls to every officer, and receives them again when written, binds and makes up the bundles of every term, which he does as fervant of the chief juftice. The chief juftice of C. B. is at the charge of the parchment of all the rolls, for which he is allowed: as is alfo the chief juftice of B. R. befides the penny for the feal of every writ of privilege and outlawry, the feventh penny taken for the feal of every writ in court under the green wax, or petit feal: the faid lord chief juftices having annexed to their offices or places the cuftody of the faid feals belonging to each court. See ESSOIN.

CLERK *of the Eftreats*, belongs to the exchequer; and, every term, receives the eftreats out of the lord-treafurer's remembrancer's office, and writeth them out to be levied for the king. He alfo maketh fchedules of fuch fums eftreated as are to be difcharged. See ESTREAT.

CLERKS *of the Green Cloth*. See GREEN-CLOTH.

CLERK *of the Hamper*, or *Hanaper*, is an officer in chancery,

cery, whose business is to receive all money due to the king for the seals of charters, patents, commissions, and writs: as also fees due to the officers for inrolling and examining the same. He is obliged to attend on the lord-chancellor, or lord-keeper, daily, in term-time; and at all times of sealing; having with him leather bags, wherein are put all charters, &c. After they are sealed, those bags, being sealed with the lord-chancellor's private seal, are delivered to the controller of the hanaper, who, upon receipt of them, enters the effect of them in a book, &c. This hanaper represents what the Romans called "fiscum," which contained the emperor's treasure; and the exchequer was anciently so called, because "in eo reconderentur hanapi et scutræ cæteraque vasa quæ in censum et tributum persolvi solebant;" or perhaps, because the yearly tribute which princes received was in hampers or large vessels full of money. There being an arrear of 10,590*l.* 12*s.* 11*d.* of several ancient fees and salaries, &c. payable out of this office: and there being a remainder of 13,698*l.* 1*s.* 11*d.* of the six-penny stamp duty on writs granted for the relief of the suitors of the court of chancery; it was enacted by the stat. 23 Geo. II. c. 25. that thereout the 10,590*l.* 12*s.* 11*d.* should be paid to the creditors of this office:—that the said duty should be made perpetual; and out of it 3000*l.* *per annum* should be paid to the "clerk of the hanaper:"—that the residue of the 13,698*l.* 1*s.* 11*d.* should be laid out in government securities, and the interest paid to the "clerk of the hanaper," who should pay 1,200*l.* to the master of the rolls:—and that in case the revenue of this office so augmented, should be more than sufficient to pay all fees, salaries, &c. the clerk should account for the surplus.

CLERK *of the Inrollments of Fines and Recoveries*, in the court of common pleas, is an officer under the three elder judges of that court, and removeable at their pleasure, who inrols and exemplifies all fines and recoveries, and returns writs of entry, &c. See INROLLMENT.

CLERK *of the Juries*, is an officer belonging to the court of common-pleas, who makes out the writs called *habeas corpus*, and *distringas*, for the appearance of juries, either in that court or at the assises; after the panel is returned upon the *venire facias*. He also enters into the rolls the awarding of these writs; and makes all the continuances, from the going out of the *habeas corpora* until the verdict is given. See JURY.

CLERK *of the Market*, is an officer of the king's house, whose duty is to take charge of the king's measures; and to keep standards of them, that is, examples of all the measures that ought to be used through the land; as of ells, yards, quarts, gallons, &c.; and of weights, bushels, &c.; and to see that all weights and measures in every place be answerable to the said standard. With regard to this officer's duty there are divers statutes, as 13 Ric. II. cap. 4, and 16 Ric. II. cap. 3, by which every clerk of the market is to have weights and measures with him when he makes assay of weights, &c. marked according to the standard; and to seal weights and measures, under penalties. The stat. 16 Car. I. c. 19, enacts, that clerks of the market of the king's or prince's household shall only execute their offices within the verge; and head-officers are to act in corporations, &c. The clerks of markets have generally power to hold a court, for which purpose they may issue out process to sheriffs and bailiffs to bring a jury before them; and give a charge, take presentments of such as keep or use false weights and measures; and may set a fine upon the offenders, &c. 4 Inst. 274. But if they take any other fee or reward than what is allowed by statute, &c. or impose any fines without legal trial; or otherwise misdemean themselves; they shall forfeit 5*l.* for the first offence; 10*l.* for the second; and 20*l.* for the third offence; on conviction before a justice of peace, &c. The "Court of the clerk of the market" is incident to every fair and market in the kingdom, to punish misdemeanours therein; as a court of "pie-powdre" is to determine all disputes relating to private or civil property. It is the most inferior court of criminal jurisdiction in the kingdom. Blackst. Com. vol. iv. See stats. 22 Car. II. c. 8. 23 Car. II. c. 12, and WEIGHTS and MEASURES.

CLERK *Marshal* of the king's house, seems to be an officer who attends the marshal in his court, and records all his proceedings. See MARSHAL.

CLERK *of the Nichils*, or *Nihils*, is an officer in the exchequer, who makes a roll of all such sums as are *nihilled* by the sheriffs upon their estreats of green-wax; and delivers the same into the lord treasurer's remembrancer's office, to have execution done upon them for the king. Stat. 5 Ric. II. c. 13. See NIHIL.

CLERK *of the Ordnance*, is an officer in the Tower, who registers all orders relating to the king's ordnance. See ORDNANCE.

CLERK *of the Outlawries*, is an officer belonging to the court of common-pleas; being a deputy to the king's attorney-general, for making out the writs of *capias utlagatum*, after outlawry; and the king's attorney's name is to every one of those writs.

CLERK *of the Paper-Office*, is an officer of the king's bench, who makes up the paper-books of special pleadings and demurrers in that court.

CLERK *of the Papers*, an officer in the court of common-pleas, who keeps the papers of the warden of the Fleet, enters commitments and discharges of prisoners, delivers out day-rules, &c.

CLERK *of the Parcels*, an officer of the exchequer. See PARCEL-*Makers*.

CLERK *of a Parish*. See PARISH *Clerk*.

CLERK *of the Parliament Rolls*, is an officer who records all things done in parliament; and engrosses them fairly into parchment rolls for the better preservation of them to posterity. Of these there are two; one of the house of lords, and the other of the house of commons.

CLERK *of the Patents*, or letters patent under the great seal; an office created 18 Jac. I. See PATENT.

CLERK *of the Peace*, is an officer belonging to the session of the peace, whose duty is at the session to read the indictments, to inrol the acts, and draw the processes; to inrol proclamations of rates for servants' wages; to inrol the discharge of apprentices; to keep the counterpart of the indenture of armour, to preserve the register-book of licences given to badgers of corn, of persons licensed to kill game, to register the estates of papists and of others not taking the oaths, &c. He also certifies into the king's bench transcripts of indictments, outlawries, attainders, and convictions, had before the justices of the peace within the time limited by statute. He is appointed by the *custos rotulorum* of the county, and liable to be discharged for misdemeanour by the justices of peace in quarter-sessions. See stats. 37 Hen. VIII. c. 1. 1 W. & M. c. 21. The following is the form of the oath prescribed by the latter statute, to be taken by the clerk of the peace, in open sessions, before he enters on his office:

"I C. P. do swear, that I have not (paid) nor will pay any sum or sums of money, or other reward whatsoever, nor given any bond or other assurance to pay any money, fee, or profit, directly or indirectly, to any person or persons whomsoever for (my) nomination or appointment.

So help me God."

He

He is also to take the oaths of allegiance, supremacy, and abjuration, and perform such requisites as other persons who qualify for offices. By stat. 22 Geo. II. c. 46. § 14, No clerk of the peace, or his deputy, shall act as solicitor, attorney, or agent at the sessions where he acts as clerk or deputy, on penalty of 50*l.* with treble costs. If the justices of the peace should discharge this officer for misconduct, the custos rotulorum is to chuse another, resident in the county, or on his default the sessions may appoint one:—the place is not to be sold, on pain of forfeiting double the value of the sum given by each party, and disability to enjoy their respective offices, &c. Stat. 1 W. & M. Sess. 1. c. 21.

Clerk *of the Pells*, belongs to the exchequer; his business is, to enter every teller's bill into a parchment roll, called *pellis receptorum;* and also to make another roll of payments, called *pellis exituum*, wherein he sets down by what warrant the money was paid. 22 and 33 Car. II. c. 22. This officer is appointed for life, by a constitution under the hands and seals of the commissioners of the Treasury, to exercise his office either by himself or his deputy. In consequence of this privilege, it has not been usual, for many years, for the clerk of the pells to execute any part of the business himself; the deputy transacts the whole, and receives and accounts with his principal for all the profits that belong to him.

Clerk *of the Petty Bag*, is an officer in chancery, whereof there are three; the master of the rolls being the chief. Their office is to record the return of all inquisitions out of every county, all liveries granted in the court of wards, all oster les mains; to make all patents of customers, gaugers, comptrollers, and aulnagers; congé d'elires for the creations of bishops; summonses of the nobility and burgesses to parliament; commissions directed to the knights and others, of every shire, for assessing of subsidies and taxes; writs for nomination of collectors for the fifteenths; and all traverses upon any office, bill, or otherwise; and to receive the money due to the king for the same. See Petty-*Bag*.

Clerk *of the Pipe*, an officer in the exchequer, who having the accounts of debts due to the king, delivered and drawn out of the remembrancer's offices, charges them down in the great roll, and is called "Clerk of the Pipe," from the shape of that roll, which is put together like a pipe; he also writes out warrants to the sheriffs to levy the said debts upon the goods and chattels of the debtors; and if they have no goods, then he draws them down to the lord treasurer's remembrancer, to write estreats against their lands The ancient revenue of the crown stands in charge to him, and he sees the same answered by the farmers and sheriffs; he makes a charge to all sheriffs of their summons of the pipe, and green wax, and takes care it be answered in their accounts. He hath also the drawing and engrossing of all leases of the king's lands; having a secondary and several clerks under him. In the reign of king Hen. VI. this officer was called "Ingrossator magni rotuli." See stat. 33 Hen. VIII. c. 22. See Pipe-*Office*.

Clerk *of the Pleas*, is an officer in the exchequer, in whose office the officers of the court, upon special privilege belonging to them, ought to sue, and be sued, in any action.

The clerk of the pleas has under him many clerks, who are attornies in all suits commenced or depending in the court of exchequer.

Clerks *of the Privy-seal*, are four officers who attend the lord-keeper of the privy-seal, or, if there be none such, the principal secretary of state; and write, or make out, all things sent by warrant from the signet to the privy-seal, and to be passed to the great seal; as also to make out privy-seals upon any special occasion of the king's affairs; as for loan of money or the like.

He that is now called "Lord Privy-Seal," seems to have been in ancient times called "Clerk of the Privy-Seal," and yet to have been reckoned in the number of the great officers of the realm. Stats. 12 R. II. c. 11. 27 Hen. VIII. c. 11.

Clerk *of the Remembrance*, an officer in the exchequer, who is to sit against the clerk of the pipe, to see the discharges made in the pipe, &c. Stat. 37 Ed. III. c. 4. The clerk of the pipe and remembrancer shall be sworn to make a schedule of persons discharged in their offices. Stat. 5 Ric. II. st. 1. c. 15.

Clerk *of the Rolls*, in chancery, an officer who searches for, and copies deeds, offices, &c.

Clerk *of the Rules*, in the court of king's bench, an officer who draws up and enters all the rules and orders made in court, and gives rules of course in divers writs. This officer is mentioned in stat. 22 and 23 Car. II. c. 22.

Clerk *of the Sewers*, is an officer belonging to the commissioners of the sewers, who writes down all things they do by virtue of their commission, and the authority given them by 13 El. cap. 9. See Sewers.

Clerk *of a ship*, is an officer appointed to take care that nothing be squandered or spent needlessly.

He is obliged to keep a register, or journal, containing an exact inventory of every thing in the loading of the vessel; as the rigging, apparel, arms, provisions, ammunition, merchandizes; as also the names of the passengers, if there be any; the freight agreed on; a list of the crew, their age, quality, wages; the bargains, purchases, sales, or exchanges the ship makes from its departure; the consumption of provision; and, in short, every thing relating to the expence of the voyage. He also registers the consultations of the captains, pilots, &c. He also does the office of a register in all criminal processes; and of a notary, to make and keep the wills of those who die in the voyage; takes inventories of their effects, &c. The clerk is not allowed to quit the vessel during the voyage, on forfeiture of all his wages, &c. In small vessels, the master, or pilot, does the office of clerk.

Clerk *of the Signet*, is an officer continually attending on the king's principal secretary; who has custody of the privy-signet, as well for sealing the king's private letters, as for such grants as pass his majesty's hands by bills signed. Of these there are four, who attend in their turn, and have their diet at the secretary's table.

The fees of the clerk of the signet and privy-seal are limited particularly by statute, with a penalty annexed for taking any thing more. 27 Hen. VIII. c. 11.

Clerk *of the King's Silver*, is an officer belonging to the common-pleas; to whom every fine is brought, after it has passed the office of the *custos brevium;* and by whom the effect of the writ of covenant is entered into a paper-book; according to which note, all the fines of that term are also recorded in the rolls of the court. After the king's silver is entered, it is accounted a fine in law, and not before. See Fine. See also Queen *Gold*.

Clerk *of the Supersedeas*, is an officer in the court of common-pleas, who makes out writs of *supersedeas* (upon the defendant's appearing to the exigent on an outlawry) whereby the sheriff is forbidden to return the exigent.

Clerk *of the Treasury*, an officer of the common-pleas who has charge of the records of the court, and makes out all the records of *nisi prius*, and has the fees due for all searches and the certifying of records into the king's bench, when a writ of error is brought. He also makes out all writs of *supersedeas de non molestanda*, which are granted for the defendants

fendants while the writ of error is depending: and all exemplifications of records, being in the treasury.

He is the servant of the chief justice, and removeable at pleasure; whereas all other officers of the court are for life. There is a secondary, or under-clerk of the treasury, for assistance; who hath some fees and allowances; and likewise an under-keeper, that always keeps one key of the treasury door, and the chief clerk of the secondary, another; so that the one cannot come in without the other.

Clerk *of the King's great Wardrobe*, keeps an account or inventory, in writing, of all things belonging to the king's wardrobe. Stat. 1 Ed. IV. c. 1. See Wardrobe.

Clerk *of the Warrants*, is an officer belonging to the court of common-pleas, who enters all warrants of attorney for plantiff and defendant in suits; and inrolls all deeds in indentures of bargain and sale, which are acknowledged in the court, or before any judges out of the court; and it is his office to estreat into the exchequer all issues, fines, and amerciaments, which grow due to the king in that court, for which he has a standing fee or allowance.

Clerks, *Regular*, a general denomination, comprehending several distinct religious orders, and assumed to denote a reformation attempted to be introduced among them. See Theatins and Fathers

Clerks, *Regular, of the Company of Jesus*. See Jesuits.

Clerks, *Regular, of St. Maieul*. See Fathers *of Somasquo*.

Clerks, *Regular, of St. Paul*. See Barnabites.

Clerks, *Misprision of*. See Misprision.

Clerk, *riding*. See Riding.

Clerks, *Six*. See Six.

Clerks, *Apostolic*, in *Ecclesiastical History*. See Jesuates.

CLERKE, Charles, in *Biography*, a celebrated English navigator, was bred up to the navy from his youth, and during the war which began in 1756 served in various actions; particularly in that between the Bellona and Courageux, where, being stationed in the mizen-top, he was carried over board with the mast, but was taken up without having received any hurt. He accompanied commodore Byron in his first voyage round the world in the station of a midshipman; and in the year 1768 he again circumnavigated the globe as master's mate and lieutenant on board the Endeavour. Soon after his return in 1775, he was appointed master and commander. In captain Cook's last voyage, Mr. Clerke was captain of the Discovery, and upon the disastrous death of that celebrated officer he succeeded to the chief command; but did not long enjoy that new dignity. Having manifested symptoms of a consumption before he left England, the disease not only continued during his whole voyage, but was aggravated by long residence in cold northern climates. Such, however, was the ardour of his mind in the prosecution of the service to which he was devoted, that declining to avail himself of the only chance for prolonging life by returning to a warmer climate, he persisted in his endeavours to explore a passage between the Asiatic and American continents, until all his officers were unanimous in their opinion that it was impracticable. Retaining his spirits and manifesting singular firmness and equanimity during the progress of his disease, his life was at length prematurely terminated on the 22d of Aug. 1779, in the 38th year of his age, within view of the coast of Kamschatka. Cook's Third Voyage, vol. iii. p. 281.

Clerke's *Harbour*, otherwise called *Port Clerke*, in *Geography*, lies to the S. of Pickersgill's cove, in Christmas sound (which see), and is much larger than the cove. On the N. of some low rocks lying off a point on Shag island is the entrance into Port Clerke at W. by S. $1\frac{1}{2}$ mile, with from 12 to 24 fathoms. Here may be procured both wood and fresh water, which are two very essential articles in such a climate. To the southward of this port about a mile, a large island appears to cover another bay from S. and S.E. winds.

Clerke's *islands*, are two islands, situated in the north Pacific ocean, on the western side of the American continent. At a distance they appear to be of considerable extent, and to contain several hills connected by land, but seeming to form a group of islands. Near the east point is a small island, having upon it 3 elevated rocks. N. lat. 63° 15'. W. long. 190° 30'.

Clerke's *rocks*, are situated on the coast of south Georgia, in about 55° 5'. S. lat. and 34° 4' W. long. 12 leagues S. 75° E. from Cooper's island.

CLERMONT, a county of America, in the state of Ohio, bounded N. on Warren county, S. on the Ohio, E. on Adams, and W. on Hamilton county. Its extent from N. to S. is 30 miles, and from E. to W. 23 miles. By the census of 1803 it contained 755 inhabitants; it has one senator in the state legislature and one representative.

Clermont, a post-town of America, in Columbia county, and the state of New York; 117 miles N. of New York, and 212 from Philadelphia. The township contains 867 inhabitants, including 113 slaves.

Clermont, a town of America, in New Hampshire, on the east bank of the river Connecticut, between Dartmouth and Charleston.

Clermont, or Clermont *en Beauvaisis*, a town of France, and principal place of a district in the department of the Oise, seated on an eminence near the Bresche; $7\frac{1}{2}$ posts N. of Paris. The place contains 1995, and the canton 10,465 inhabitants: the territory includes 145 kiliometres and 18 communes.

Clermont, a city of France, and capital of the department of Puy-de-Dôme; before the revolution the capital of Auvergne, and the see of a bishop, suffragan of Bourges: seated on a small eminence at the foot of a lofty mountain. The place, comprehending the N. S. and S. E. cantons, contains 24,478, and the 3 cantons 38,485 inhabitants: the territory of the first canton includes $52\frac{1}{2}$ kiliometres and 5 communes; that of the second $67\frac{1}{2}$ kiliometres and 2 communes: and that of the third 120 kiliometres and 3 communes. The commerce of this city consists in corn, wine, wool, woollen stuffs, tammies serges, linen, lace, &c.

Near this place are some mineral springs, and the water of a brook, which passes through one of the fauxbourgs, petrified a wooden bridge to perfect stone, so that carriages can pass over it. A council was held here in the year 1095, to determine on the crusade against the infidels in the Holy Land, during the pontificate of Urban II. It is called Clermont-Ferrand from the town of Montferrand being united to it, and forming one of its fauxbourgs; distant $23\frac{1}{4}$ posts W. from Lyons, and $46\frac{3}{4}$ S. from Paris. N. lat. 45° 46' 44". E. long. 3° 5' 2".

Clermont, a town of France, in the department of the Hérault, and chief place of a canton, in the district of Lodève, 20 miles W. of Montpellier. The place contains 5430, and the canton 11,440 inhabitants: the territory includes $167\frac{1}{2}$ kiliometres and 15 communes. The chief trade consists in wool and cattle, with manufactures of cloth and hats for exportation.

Clermont, a town of France, in the department of the Meuse, and chief place of a canton in the district of Verdun; seated on an eminence surrounded with woods and pastures; 4 leagues W.S.W. of Verdun. The place contains 1598, and the canton 9660 inhabitants: the territory

tory includes 207½ kilometres and 17 communes. N. lat. 49° 7'. E. long. 4°.

CLERMONT, a town of France, in the department of the Lot and Garonne; 3 leagues W. of Agen.

CLERMONT, a town of France, in the department of the Sarthe, 1 league N.E. of La Flèche.

CLERMONT *Manufcript, Codex Claromontanus* or *Regius* 2245, in *Biblical Literature,* is a Greek-Latin copy of St. Paul's Epiftles, found in the monaftery of Clermont en Beauvaifis in France, and ufed by Beza, together with the Cambridge MS. in preparing his edition of the New Teftament.

Wetftein charges Beza with a miftake in regard to its having been preferved at Clermont, and fays that he confounded it with the Cambrige MS. He conjectures that it was brought into Switzerland from the monaftery of Cluny which the Swifs plundered, and that Beza defignedly concealed the manner in which it came into his poffeffion. But this reflection on the part of Wetftein is thought to be partial and unjuft; as Beza, who had procured it either by purchafe or gift, and thus refcued it from deftruction, might have openly avowed the fact, without incurring the charge of a literary theft, or being in danger of having it redemanded. From the hands of Beza it came into the Putean library, a library which derived its name from the family of Du Puy; the proprietor being Jacques du Puy, who was librarian to the king of France, and died in 1656. Du Puy bequeathed it with all his other MSS. to the Royal Library at Paris, where it is now preferved and marked Cod. Græc. 107; and it is noted D in the fecond part of Wetftein's New Teftament. This copy is written on vellum in Greek and Latin, with fome mutilations. According to the accounts of Wetftein and Sabatier, thirty-fix leaves were cut out of it, in the beginning of the laft century, probably by John Aymon, a noted literary thief, who robbed both the royal and private libraries; and thefe leaves were fold in England; but they were fent back by lord Oxford in 1729. The MS. is therefore again complete, as there fails only the covering, in which the ftolen fheets had been inclofed, which is kept in the Britifh Mufeum, and filled with the letters that paffed on the occafion, as a monument of this infamous theft.

This manufcript, like other codices Græco-Latini, has been accufed of having a Greek text that has been altered from the Latin. Wetftein has produced feveral examples, of unequal weight, in fupport of this charge. Neverthelefs, though perhaps the charge is not wholly unfounded, it harmonizes with other ancient verfions, more efpecially the Syriac; and as no one can fuppofe, that this MS. has been corrupted from them all, no other caufe of coincidence can be affigned befides its high antiquity. From feveral examples, produced by Michaelis in confequence of having examined only a few chapters, it may be concluded, that the fufpicion of its having been altered throughout from the Latin is ungrounded. Mill contended that the Codex Claromontanus was the fecond part of the Cantabrigienfis: but Wetftein has fufficiently confuted this opinion, and fhewn that the former is by no means connected with the latter, as appears from the difference of their form, their orthography, and the nature of the vellum on which they are written. This has likewife been confirmed by Griefbach in his " Symbolæ Criticæ," who has examined both MSS

Beza was the firft who made ufe of the Clermont MS.; it was afterwards collated by Morinus, with a view of difcovering readings in fupport of the Vulgate; more copious extracts were given in the London Polyglot, which Mill transferred to his Greek Teftament; and Wetftein has twice collated it himfelf in 1715 and 1716. The Latin verfion publifhed by Sabatier was taken from this manufcript and the Sangermanenfis.

With regard to the antiquity of this MS. Sabatier eftimates it at 1200 years; and it is fuppofed by Montfaucon to have been written in the 7th century. He has defcribed it in his "Palæographia Græca," p. 217), and in the plate fronting this page he has given a fac-fimile of its characters. Though written in Uncial letters, it has accents and marks of afpiration, of which Montfaucon says; "fecundâ manu, ut videtur, nec diu, ut creditur, poft defcriptum codicem adjecti funt." The marks of afpiration, however, are not of the modern femicircular form. This MS. was probably written in the weft of Europe, not only becaufe it has a Latin tranflation, but becaufe the epiftle to the Hebrews is written at the end; and in the catalogue of the books of the New Teftament placed after the epiftle to Philemon, no mention is made of the epiftle to the Hebrews. To this may be added, that neither Simon nor Wetftein has noted that this epiftle is written even by a later hand, and was therefore wholly excluded from the canon by the original writer of the manufcript. Confequently, as the epiftle to the Hebrews was, during a confiderable time, rejected by the Church of Rome, but not by the Greek Church, it is certain, that the Codex Claromontanus was written in a country, that was under the dominion of the former. Michaelis's Introd. to the New Teftament by Marfh, vols. ii. and iii. See CAMBRIDGE *Manufcript.*

In the above-mentioned catalogue the Latin order of the gofpels is likewife obferved, *viz.* Matthew, John, Mark, Luke, which furnifhes additional evidence that it was written by a member of the Latin church.

CLERODENDRUM, in *Botany,* (from κλῆρος, *lot* or *fortune,* and δένδρον, *a tree;* fortunate tree). Linn. Gen. 789. Schreb. 1057. Willd. 1202. Gært. 340. Juff. 106. Vent. 2. 316. (Peragu, Encyc. Meth.) Clafs and order, *didynamia angiofpermæ.* Nat. ord. *Perfonatæ,* Linn. *Vitices,* Juff. *Pyrenaceæ,* Vent.

Gen. Ch. *Cal.* Perianth one-leafed, campanulate; fegments five, ovate-acute, broader than the tube of the corolla, permanent. *Cor.* monopetalous, irregular; tube long, flender; border regularly cleft, upper fegments more deeply divided. Filaments four, filiform, much longer than the corolla, afcending and widely fpreading through its two upper fiffures; anthers fimple. *Pift.* Germ roundifh; ftyle the length of the filaments; ftigma fimple. *Peric.* Berry, or rather drupe, enclofed by the inflated calyx, one-celled, with four ftones, (pyrenes, Gært.) often feparating into four parts in the ftate of maturity; ftones or pyrenes one-celled, each containing a fingle kernel or feed.

Eff. Ch. Calyx five cleft, campanulate. Tube of the corolla flender; border five-cleft, equal. Stamens very long, projecting through the two upper fiffures of the corolla, widely fpreading. Berry or drupe one-celled; ftones four, each with a fingle feed.

Obf. There is a great refemblance in the general habit and feveral prominent characters between the fpecies of this genus and thofe of volkameria. It differs from the latter in having a fimple, not a bifid ftigma, and one-feeded, not two-feeded ftones. The number of kernels or feeds is, however, in both genera exactly the fame.

Sp. 1. C. *infortunatum,* Linn. Sp. Pl. 1. Mart. 1. Poir. 1. Willd. 1. Gært. tab. 57, fig. 1. Lam. Ill. tab. 544. Lour. 387. (Peragu, Rheed. Hort. Mal. 2. tab. 25.) "Leaves heart-fhaped, tomentous." A fhrub about three feet high, (feven feet, Lour.) *Roots* fibrous, yellow or red-

difh

diſh. *Stems* cylindrical near the bottom, quadrangular above with a deep groove on each of the ſides, cloathed with a ruſſet down. *Leaves* oppoſite, without ſtipules, cordate acute, entire, nerved; their upper ſurface deep green, with a few very ſhort, fine, ſcattered hairs; their under ſurface cloathed with a thick, cloſe, ruſſet down. *Flowers* yellowiſh white, (bright ſcarlet, Lour.) in a terminal pyramidal panicle; each peduncle terminated by one or two pedicelled flowers. *Fruit* blackiſh when ripe. A native of ſandy places on the coaſt of Malabar and other parts of the Eaſt Indies. 2. C. *fortunatum*, Linn. Sp. Pl. 2. Mart. 2. Poir. 2. Willd. 2. Oſbeck. It. tab. 11. "Leaves lanceolate, quite entire." A ſhrub. Stems cylindrical, ſlightly hoary. *Leaves* two or three inches long, more than an inch broad, oppoſite, petioled, naked, nerved, a little decurrent along the petioles; petioles a third of the length of the leaves, rather cylindrical near the baſe, ſtriated and almoſt flat above. *Flowers* yellowiſh white, axillary, in ſmall corymbs; common peduncles an inch long, narrow, ſcarcely pubeſcent, dividing into ſhort branched bifurcations, each ſupporting a ſingle flower; calyx much expanding, deeply divided; ſegments ovate, acute, ſmooth, permanent; tube of the corolla ſcarcely longer than the calyx; filaments nearly twice the length of the corolla, capillary; anthers oval, very ſmall; piſtil ſhorter than the ſtamens. A native of the iſland of Java and other parts of the Eaſt Indies. 3. C. *calamitoſum*, Linn. Mant. 90. Mart. 4. Poir. 3. Willd. 3. (Volkameria alternifolium, Burm. Ind. tab. 44??) "Leaves oval, ſomewhat toothed, naked." *Stem* erect, woody. *Leaves* oppoſite, petioled; petioles one-third of their length. *Flowers* ſmaller than thoſe of the preceding ſpecies, axillary, in a ſpreading panicle. A native of Java. 4. C. *phlomoides*, Linn. jun. Suppl. 292. Mart. 3. Poir. 4. Willd. 4. Vahl. Symb. 2. (Volkameria multiflora, Burm. tab. 45. fig. 1). "Leaves egg ſhaped, entire, toothed and angular; peduncles axillary, with about three flowers." A hoary ſhrub. *Stems* woody, whitiſh, pubeſcent, nearly cylindrical. *Leaves* oppoſite, petioled, acute, thick, tomentous, yellowiſh white on both ſides, entire near the baſe, toothed and almoſt angular from the middle to the ſummit, nearly as broad as long; petioles about half an inch long, a little ſhorter than the leaves. *Flowers* white, forming altogether a ſpreading panicle; branches axillary, from the upper leaves; peduncles tomentous, white, nearly the length of the leaves; bractes ovate, acute, entire, tomentous, white; calyx campanulate, divided nearly to the middle; ſegments open, lanceolate, very acute; tube of the corolla at leaſt three times longer than the corolla, ſlender, enlarged near its orifice; diviſions of the border five, ſhort, ovate, a little reflexed; ſtamens half as long again as the corolla, leſs ſpreading than in the other ſpecies. A native of the Eaſt Indies; found by Koenig and Sonnerat. 5. C. *umbellatum*, Poir. 5. "Leaves coriaceous, egg-ſhaped, ſhining, quite entire; flowers ſomewhat umbelled." A ſhrub. *Stems* tetragonous, quite ſmooth, ſtriated, reddiſh or purple. *Leaves* oppoſite, petioled, quite ſmooth, very acute, about three inches long, one inch broad; petioles very ſhort. *Flowers* reddiſh, in a terminal four-rayed umbel; peduncles twice bichotomous or trichotomous, with one flower at the ends of the laſt diviſions; calyx pubeſcent, tubular, cleft to the middle; ſegments narrow, linear; tube of the corolla more than an inch long, ſlender; lobes of the border rather large; filaments twice the length of the corolla, purple. A native of Africa; found by Smeathman; deſcribed from a ſingle branch in the herbarium of La Marck. 6. C. *ſquamatum*, Mart. 7. Poir. 6. Willd. 5. Vahl. Symb. 2. p. 74. "Leaves heart-ſhaped, obſcurely angular; branches of the panicle dichotomous, ſmooth." *Stems* fruteſcent erect; branches ſmooth, tetragonous, with a groove on each ſide. *Leaves* from three to five inches long, from two to four broad, with a deep ſinus at their baſe, oppoſite, acute, entire, or ſometimes obſcurely toothed, three or five-nerved, tender, ſmooth; pale green underneath, and covered with minute, roundiſh, umbilicated ſcales; deeper green above, and cloathed with a few ſmall very ſhort hairs; petioles at firſt villous, afterwards ſmooth, at leaſt as long as the leaves. *Flowers* in a large, terminal, ſpreading, ſmooth, panicle; peduncles deeply furrowed, thrice dichotomous, ſometimes trichotomous at the ſecond diviſion; pedicels one-flowered, filiform; lower bractes oppoſite, petioled, oppoſite, heart-ſhaped, ſlightly villous; upper ones ſeſſile, narrow, awl-ſhaped; calyx deeply divided; ſegments quite ſmooth, a little coloured, oval, acute, permanent; tube of the corolla ſlender, three times the length of the calyx; diviſions of the border lanceolate, acute; ſtamens projecting two inches out of the corolla; piſtil of the ſame length. A native of the Eaſt Indies. Specimens ſent by Sonnerat are preſerved in the Herbarium of La Marck, from which Vahl formed his ſpecific character and deſcription. Poiret, who examined the ſame ſpecimens, was induced by appearances to ſuſpect that the ſuppoſed ſcales on the under ſurface of the leaves are really either a kermes, or ſome kind of paraſitic fungus, allied to æcidium. If this ſuſpicion be well founded, the plant is miſnamed, and loſes the moſt prominent part of its ſpecific character. 7. C. *trichotomum*, Mart. 6. Poir. 7. Willd. 6. Thunb. Jap. 256. (Seo kuſits, vulgo kuſaggi, Kæmpf. Amœn. 827. Ic. Select. tab. 22.) "Leaves lobed and undivided, broad-egg-ſhaped, quite entire; panicle trichotomous." *Stems* fruteſcent; branches ſmooth, tetragonous, with a deep furrow on each ſide. *Leaves* oppoſite, petioled; lower ones larger, three-lobed; upper ones undivided; uppermoſt very ſmall; all acuminate, ſmooth, entire, nerved, deep green above, paler underneath; petioles ſlightly pubeſcent, ſhorter than the leaves. *Flowers* white, in a very large panicle, without bractes; peduncles and pedicels ſmooth, compreſſed at the diviſion; calyx inflated, contracted above, with five angles, ſhrivelling but permanent, much wider and ſhorter than the corolla, ſmooth; ſegments keeled, acute, erect; tube of the corolla an inch long, filiform, a little bent; diviſions of the border oblong, obtuſe, ſpreading; filaments inſerted into the tube of the corolla within the throat, whitiſh, divaricated at the bottom; anthers cordate-ovate; germ ſuperior, tetragonous, ſmooth; ſtyle longer than the ſtamens; ſtigma ſimple, truncated. *Fruit* an almoſt globular capſule, ſmooth, with four furrows, four-celled, four-valved. *Seeds* ſmooth, one in each cell. A native of Japan. The leaves have a ſtrong poiſonous ſmell like mandragora. *Obſ.* The fruit of this ſpecies, as deſcribed by Thunberg, is altogether at variance with the eſſential generic character. 8. C. *diverſifolium*, Mart. 8. Poir. 8. Willd. 7. Vahl. Symb. 2 75. "Leaves entire and three-lobed, egg-ſhaped; branches of the panicle dichotomous, villous; pedicels racemed." *Stems* woody; branches tetragonous, with a furrow on each ſide, villous at the top. *Leaves* from ſix to eight inches long, five or ſix broad, oppoſite, petioled, ſmooth, deep green above, covered underneath with ſcales ſimilar to thoſe of C. ſquamatum; lower leaves very large, five-lobed, enlarged at the baſe; lobes acute, middle one much longer, acuminate; upper leaves ſmaller, narrowed at the baſe, three-lobed; two lateral lobes ſhort, rather acute; terminal leaves ſmall, entire, lanceolate, ſeſſile, or narrowed into a petiole. *Flowers* in a large terminal panicle

cle eight or ten inches long, villous in all its ramifications; common peduncles opposite, expanding, once or twice dichotomous, terminated by simple racemes; calyx pubescent, with oblong acute segments; tube of the corolla about an inch long, slightly pubescent, two-lipped; upper lip bifid, with erect linear divisions; lower one three-lobed, the two lateral lobes shorter than that in the middle; filaments nearly twice the length of the corolla. A native of the East Indies. Description formed by Vahl from specimens communicated to La Marck by Sonnerat. 9. C. *paniculatum*, Linn. Mant. 90. Mart. 5. Poir. 9. Willd. 8. Vahl. Symb. 2. 74. "Leaves lobed, serrated; panicles very large." Linn. "Leaves five-lobed, toothed, smooth; panicle brachiate; axils woolly." Vahl. *Stems* frutescent; branches smooth, tetragonous, deeply furrowed on each side, purple. *Leaves* five or six inches long, opposite, petioled, heart-shaped; lobes unequal, lanceolate, acute, edged with remote small teeth; petioles cylindrical, striated, about the size of a pigeon's quill; axils garnished with long curling whitish hairs. *Flowers* in a vast, much branched, expanding panicle, which is about six inches long; peduncles opposite, smooth, many times dichotomous; pedicels capillary, one-flowered; segments of the calyx lanceolate, smooth; corolla about an inch long; tube filiform, divisions of the border oblong. A native of the East Indies.

Clerodendrum *fruticosum spinosum*, Brown. Jam. See Volkameria *aculeata*.

CLEROMANCY, derived from κληρος, *lot*, and μαντεια, *divination*, a kind of divination performed by the throwing of dice, or little bones; and observing the points or marks turned up.

At Bura, a city of Achaia, was a temple, and a celebrated oracle of Hercules; where such as consulted the oracle, after praying to the idol, threw four dies, the points whereof being well scanned by the priest, he was supposed to draw an answer from them.

Something of this kind seems to have been practised with regard to Jonah. See Jonah, i. 7.

CLERORUM, in *Ancient Geography*, an episcopal see of Asia, in Phrygia Salutaris.

CLEROTI, among the Athenians, a kind of public arbitrators. See Diætetæ.

CLERVAL, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Baume; 7 leagues N.E. of Besançon. The place contains 1118, and the canton 9005 inhabitants: the territory includes 217½ kiliometres, and 25 communes.

CLERVAUT, a town of France, in the department of the Vienne; 5 miles N. of Chatellerault.

CLERVAUX, a town of France, in the department of the Forêts, and chief place of a canton, in the district of Dieckirch; the place contains 528, and the canton 6763 inhabitants: the territory includes 262½ kiliometres, and 10 communes.

CLERY, a town of France, in the department of the Somme, and district of Pèrone; 1 league N.W. of it.

Clery, *Notre-Dame de*, a town of France, in the department of the Loiret, and chief place of a canton in the district of Orleans; 7 miles S.W. of Orleans. The place contains 2224, and the canton 4473 inhabitants: the territory includes 125 kiliometres, and 4 communes.

CLESSIDES, in *Biography*, an ancient painter, who, imagining himself slighted by Stratonice, painted a satyrical representation of that queen, in the arms of a fisherman, with whom, it was whispered, she was enamoured; hung it up to public view in the port of Ephesus, and then took to his oars and got away. The picture was admirable; and Stratonice, valuing the art more than her own reputation, would not suffer it to be removed. Orlandi. Della Valle, Vite dei Pitt. Ant.

CLETÆBENI, in *Ancient Geography*, a people of Arabia Felix, situated near the Red Sea, between the Sabæans and Minæans.

CLETCH, in *Rural Economy*, a term signifying a young brood, as of chickens, &c.

CLETHARRO, in *Ancient Geography*, a town placed by Ptolemy in Arabia Petræa.

CLETHRA, in *Botany*, (κληθρα, Theoph. lib. i. cap. 10, which Gaza translates *alnus*, alder. H. Stephens derives it from κλειω, *claudo*, to close or shut up, referring probably to the situation of the seeds in the female catkin of the alder.) Linn. Gen. 553. Schreb. 751. Willd. 872. Gært. 383. Juss. 160. Vent. ii. 462. Class and order, *decandria monogynia*. Nat. ord. *Bicornes*, Linn. Vent. *Ericæ*, Juss.

Gen. Ch. *Cal.* Perianth one-leafed, five-cleft, (five-leaved, Gært.); segments concave, egg-shaped, erect, permanent. *Cor.* Petals five, longer than the calyx, oblong, enlarged towards the summit, half-expanding, obtuse. *Stam.* Filaments ten, a little longer than the petals, awl-shaped; anthers forked. *Pist.* Germ superior, roundish; style permanent; stigma trifid. *Peric.* Capsule roundish, enclosed in the calyx, three-celled, three-valved; partitions contrary to the valves. *Seeds* six or eight in each cell, attached to an angular receptacle, which is finally deciduous.

Eff. Ch. Calyx five-cleft. Petals five. Stigma trifid. Capsule three celled, three-valved.

Sp. 1. C. *alnifolia*, alder-leaved clethra, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Gært. i. tab. 63. Lam. Ill. Pl. 369. fig. 1. (Alnifolia americana, Pluk. Alm. tab. 115. fig. 1, 2. Catesb. Car. i. tab. 66.) "Shrubby; leaves obovate-lanceolate, serrated, smooth on both sides; racemes simple, in form of spikes." *Roots* spreading. *Stems* from eight to ten feet high; branches diffuse, cylindrical, pubescent near the summit. *Leaves* about three inches long, an inch and quarter broad in the middle, alternate; on short petioles, nerved. *Flowers* white, numerous, in terminal racemes; bractes linear, shorter than the flowers, caducous. A native of Virginia and Carolina, in moist ground, and on the banks of rivulets. 2. C. *tomentosa*, Lam. 2. (C. alnifolia, β. Hort. Kew.) "Leaves tomentous, hoary underneath." Smaller than the preceding species. Peduncles, calyxes, and bractes very villous. *Flowers* white. A native of Virginia and Carolina. 3. C. *paniculata*, Hort. Kew. ii. p. 73. Mart. 2. Willd. 2. "Shrubby; leaves lanceolate, naked on both sides; flowers panicled, bracteate." Panicle not composed of racemes, narrow, elongated; peduncles pubescent, white. A native of North America, flowering from August to October. 4. C. *arborea*. "Leaves oblong, acuminate, serrated, smooth; racemes panicled; flowers without bractes; peduncles hirsute." A tree. *Calyxes* obtuse. *Receptacles* of the seeds not solitary at the base of each cell, as in C. alnifolia, but fixed laterally at the top of a short three-sided central column, with which the partitions are in contact. A native of Madeira: introduced by Masson in 1784. 5. C. *tinifolia*, Mart. 4. Willd. 4. Poir. Sub. Tinier. Swartz. Prod. 74. Ind. Occid ii p. 845. (Tinus occidentalis, Linn. Sp. Pl. p. 530. Volkameria arborea, Brown. Jam. 214. tab. 21. fig. 1. Baccifera arbor calyculata, Sloan. Jam. ii. tab. 198. fig. 2, but not the description.) "Leaves oblong, quite entire, hoary underneath; racemes panicled; flowers without bractes, peduncles tomentous." A shrub, with the habit of the other species fpecies of clethra, twelve or fourteen feet high; branches fpreading. *Leaves* alternate, petioled, fmooth, and green on their upper furface, acute, narrowed at the bafe. *Flowers* in axillary and terminal racemes; calyx a little pubefcent, with five equal fegments; petals five, a little enlarged, connivent at the bafe; ftamens ten; filaments free, not projecting; ftigma trifid. *Fruit* a capfule refembling a berry, or rather a drupe, fmooth, roundifh, three-celled, three-valved. A native of Jamaica.

Obf. Linnæus, who was imperfectly acquainted with the fructification, made it a diftinct genus, and placed it in his clafs Enneandria. Juffieu, without venturing to alter this difpofition, conjectured that its fuppofed berry would prove a capfule, and that the plant muft be affociated with clethra. Subfequent obfervations have confirmed his opinion.

Clethra, in *Gardening*, contains a plant of the hardy deciduous flowering fhrubby kind; of which the fpecies is alder-leaved clethra (C. *alnifolia*), which is a fhrub that has the roots fpreading far on every fide, and fending up many ftems, from eight or ten to fourteen feet high, which are covered with a greyifh bark, and divide into many round alternate branches. The leaves are about three inches long, and an inch and a quarter broad in the middle; of a deep green on their upper fide, and a whitifh green underneath, alternate, and on very fhort petioles. The flowers are on loofe fpikes from four or five inches to a fpan long; the petals are white. They appear in July, and, when the feafon is mild, fome fpikes are produced in October. It is a native of North America.

Method of Culture. It is capable of being increafed by feeds, layers, and fuckers.

The feeds procured from America fhould be fown in pots of light mould, and removed into the fhade during fummer, and fheltered in winter, as fometimes the plants do not come up till the fecond fpring after they have been fown.

And the layers fhould be made from the young fhoots in autumn, and water given them the following fummer; and in the autumn after, or when well rooted, they fhould be taken off and planted out in feparate pots, or in the places where they are to remain.

In the laft mode, the fuckers from the roots may be removed in the autumn, or early fpring months, fibres being preferved to them as much as poffible, and be planted out in pots, or other places where they are to remain.

This is a very ornamental fhrub, particularly during the time of its bloom, but fhould have a rather moift fituation.

CLETHRITES *lapis*, a name given by the ancients to fuch pieces of foffile wood as fhewed a grain refembling that of the wood of the alder.

CLETHY, in *Geography*, a river of South Wales, which rifes in Pembrokefhire, about 5 miles S.E. of Newport, and joins the Dungledy, 4 miles N. of Pembroke.

CLETON, a river of Wales, which runs into the Dee, two miles below Bala, in Merionethfhire.

CLETTER, a river of Wales, in Cardiganfhire, which runs into the Dovy, a few miles below Machynlleth.

CLEVELAND, a diftrict of England, in the county of York, on the borders of Durham.

Cleveland, a pleafant fmall town of America, in the ftate of Ohio, and county of Trumbull, favourably fituated on the borders of lake Erie, at the mouth of Cayahoga river.

CLEVES, a town of Germany, in the circle of Weftphalia, and capital of a duchy to which it gives name; but fince the French revolution, the principal place of a diftrict in the department of the Roer; the place contains 4243, and the canton 8353 inhabitants; and the territory includes 16 communes. It is fituated on the river Kermifdal, about two miles from the Rhine, on the brow of a hill, furrounded with walls, but not much fortified, and confifts of feveral irregular ftreets. The land about the town is very well cultivated, which is owing to the abolition of the great land-holders. About half a mile from the town is a very pleafant park, with a clofe avenue of noble plane trees; and near this agreeable fpot is a mineral fpring, which in fummer is much frequented. The Dutch language and coins are current here, as well as the High German. The Roman Catholics, the Lutherans, the Calvinifts, and the Mennonites, have their refpective churches, and the Jews have a fynagogue. In the fame department, in the diftrict of Cleves, and about the diftance of five miles from the Rhine, is the town of Calcar: the place containing 1304, and the canton 9345 inhabitants, and the territory including 22 communes. See Calcar.

Cleves is about 10 miles E.S.E. of Nimmeguen. N. lat. 51° 50′. E. long. 5° 50′.

Cleves, *Duchy of*, forming, fince the revolution, a part of the French department of Roer, is a principality of Germany, which belonged to the king of Pruffia, and is bounded on the north by Overyffel and the bifhoprick of Munfter, on the eaft by the former and the county of Rechlinghaufen, on the fouth by the county of Mark and duchy of Berg, and on the weft by Guelderland and Brabant. It is about 50 miles in length, and 13 in breadth; the air is very healthy, but the foil is unequal. On the eminence are feen fields, woods, and extenfive forefts, bordered by towns and villages; and on the banks of the Rhine, which runs through this country, are extenfive fine paftures, which feed a great number of cattle. The produce is corn, tobacco, and all forts of vegetables. Game is plentiful, and the rivers abound with all forts of fifh. The manufactures of filk, cloth, linen, lace, pipes, &c. are very confiderable. The whole country contains 22 towns, the principal of which are Cleves, Calcar, Nieder-Wefel, Duifburg, Xanton, Rees, and Emmerich, in which perfons of all religious fects are allowed freedom of worfhip. The population, according to the eftimate of Hoeck (edit. 1801), amounts to 100,000 perfons. The principal rivers are the Rhine, Meufe, Ruhr, Emfer, Lippe, and the Iffel. The revenues of Cleves and Mark are faid to have amounted to a million of crowns; and the king of Pruffia, as duke of Cleves, was accuftomed to pay towards the charges of the empire 1208 florins, and to the Imperial chamber 676 crowns. See Roer.

Cleves, a town of America, in the ftate of Virginia; two miles north of Port Royal.

CLEUSIS, in *Ancient Geography*, a river which ran from north to fouth, between Mela and the lake Benacus.

CLEVUM, or Glevum, a town of Great Britain, which, according to the Itinerary of Antonine, lay on the route from Ifca or Caerleon to Calleva or Silchefter, between Ariconium near Rofs, and Duroconovium or Cirencefter. It was the prefent city of Gloucefter.

CLEVVY, in *Agriculture*, a term fometimes provincially applied to a fort of draft-iron of a plough.

CLEW-*bay*, in *Geography*, a large bay on the weft coaft of Ireland, in the county of Mayo, which has been fometimes called Newport bay. It is twelve miles from eaft to weft, and from five to feven miles from north to fouth. At the bottom it is crowded with fmall iflands, between fome of which there is deep and fafe anchorage. It is fheltered on the north and fouth by the mountains of Burrifhoole and Morifk, and defended from weftern ftorms by the high and rocky ifland of Clare. There are two fmall ports on this bay, Newport Prat and Weftport, which will be mentioned in their proper places. The entrance S. of Clare Ifland is in about 53° 46′. N. lat. and the whole bay is between 9° 27′ and 9° 46′ long. W. from Greenwich. Beaufort. M'Kenzie.

CLEW, or CLUE, *of the fail of a fhip*, is the lower corner of it which reaches down to that earing where the tacks and fheets are faftened; fo that when a fail is made goring, or floping by degrees, fhe is faid to have a *great clew:* and a fhip is faid to have a great clew, when fhe has a very long yard, and fo has much canvas in her fails.

CLEW *garnet*, a rope faftened to the clew of the fail, and from thence running in a block feized to the middle of the main and fore-yard. Its ufe is to haul up the clew of the fail clofe to the middle of the yard, in order to its being furled. Hence to *clew*, or *clue up*, is to haul up the clews of a fail to its yard by means of the clew-lines.

CLEW-*line* is the fame to the top-fails, top-gallant-fails, and fprit-fails, that the clew-garnet is to the main-fail and fore-fail, and has the very fame ufe. In a guft of wind, when a top-fail is to be taken in, they firft haul home the lee clew-line, and by that means the fail is taken in much eafier.

CLEYER, ANDREW, M.D., in *Biography*, was born at Caffel, near the Rhine, the beginning of the 17th century. His difpofition leading him to the ftudy of medicine, and natural hiftory, after being initiated in the knowledge of pharmacy and furgery, he accepted the office of phyfician to the Dutch fettlement at Batavia, in the ifland of Java, where he appears to have refided feveral years. He had been previoufly elected a member of the Imperial Academy, whofe Tranfactions he enriched with numerons curious and interefting communications, the titles of which follow: "An Account of Hydatids, found in a Human Stomach," "Of the Cuftom of the Indians, of taking Opium," "ut ad venerem fe excitent." They think opium, taken in the quantity of a drachm in the day, has the power of prolonging life. In Java, he fays, the elephantiafis made its firft appearance about twenty years before he arrived in the ifland; from his defcription of the difeafe, it appears to have been the yaws. He defcribes 289 plants growing in the ifland, with the ufes they are put to by the natives; particularly the moxa, ginfeng, and the tea-plant; of the greater part of which there are engravings, elegantly, Haller fays, but not very accurately, drawn. His publications are, "Specimen Medicinæ Sinicæ, five Opufcula Medica ad Mentem Sinenfium." Francof. 1680, 4to. It confifts of feveral treatifes on the pulfe, as defcribed by the Chinefe; of the indications of difeafe, taken from the pulfe, colour of the tongue, &c. The obfervations on the medicine of the Chinefe, in part tranflated from their books, was the work of William Ten Rhyne, who was alfo refident in Java, and who complains that they were publifhed without his knowledge. Haller Bib. Med. Anat. Chir. Bot.

CLEYERA, in *Botany*, Thunb. See TERNSTRŒMIA.

CLEYN, or CLENN, FRANCIS DE, in *Biography*, was a native of Roftock, in Germany; having an inclination towards the fine arts, he went to Rome, where he ftudied four years. He afterwards came to England, and was employed by James I. to make defigns for ornamental tapeftries. His talent lay chiefly in painting friezes, and other grotefque decorations, in which he introduced fea-nymphs, tritons, and cupids; with fufficient grace of defign and freedom of execution. Several paintings by him of this defcription ftill exift at Holland houfe; and feveral of them were engraved by himfelf and others. He died in London, in the year 1658. Pilkington. Strutt.

CLIBADIUM, in *Botany*, (κλιβαδιον, Diofcor.) Linn. Gen. 1329. Schreb. 1430. Willd. 1670. Juff. 191. Clafs and order, *monœcia pentandria*. Nat. Ord. *Corymbiferæ*, Juff.

Gen. Ch. *Cal. common* imbricated; fcales egg-fhaped, acute. *Cor.* Florets tubular, funnel-fhaped, five-cleft; male florets in the difk, numerous, pedicelled; female ones in the ray, three or four. *Stam.* in the males; filaments five, very fhort, capillary; anthers oblong, approximating, but not united. *Pift.* in the males abortive; germ very fmall, fuperior; ftyle filiform; ftigma fimple; in the females, germ roundifh, inferior; ftyle filiform; ftigma bifid. *Peric. common* none, except the permanent, coloured calyx; *proper*, to the males, none; to the females, a roundifh, umbilicated drupe, with a yellow vifcid juice. *Seeds* one in each drupe, heart-fhaped, compreffed.

Eff. Ch. Common calyx imbricated. Anthers of the male florets approximating, not united; female florets three or four. Drupe umbilicated.

Sp. C. *furinamenfe*, Linn. Mant. p. 294. Mart. Poir. Willd. (C. fœtidum; Allemand MSS.) *Leaves* oppofite, petioled, egg-fhaped, acuminate, acutely crenate, fcabrous. *Flowers* white; peduncles oppofite; common calyx violet-coloured, when ripe. *Drupe* green. A native of Surinam.

CLIBANARII. See CATAPHRACTI or CATAPHRACTARII.

CLIBANUS, in *Ancient Geography*, a town of Afia Minor, in the interior of Ifauria, according to Pliny.—Alfo a mountain of Italy, in Magna Græcia, in the vicinity of the Lacinian promontory. Pliny.

CLICH, a fabre in ufe among the Turks. It is curved and very large. They have another fabre, which cuts with one fide or edge only, and has folid iron along the back of it. This is called *gadara*, and is lefs curved than the *clich*. They have alfo a third kind of fabre, which is ftraight, rounded, and fharp at the end, and cuts with both edges. It is called *palas*.

CLICHY *la Garenne*, in *Geography*, a town of France, in the department of Paris; one league W.N.W. of Paris.

CLIDE or IAUCLIDE, in *Ancient Military Language*, a long piece of wood or ftrong plank, held in its pofition by a counter-weight, which, when loofened from the fame, lets fly a great weight of ftones into befieged fortreffes. Thefe machines were in ufe under Charlemagne.

CLIDES *infulæ*. See CLEIDES.

CLIDOMANCY, from κλεις, a *key*, and μαντεια, *divination*, a fpecies of divination performed by means of keys. See DATYLIOMANCY.

CLIE, LE, in *Geography*, a lake of Upper Canada, about 38 miles long, and 30 broad; the waters of which communicate with thofe of lake Huron. N. lat. 44° 20′. W. long. 80°.

CLIENT, CLIENS, among the Romans, a citizen who put himfelf under the protection of fome great man, who, in that relation, was called his patron, *patronus*.

The patron affifted his client with his protection, intereft, and eftate, advifed him in points of law, managed his fuits, took care of him as of his own child, and to the utmoft of his power, contributed to fecure his peace and happinefs: and the client gave his vote for his patron, when he fought any office for himfelf, or his friends. Clients owed refpect to their patrons, as thefe reciprocally owed them their protection.

This right of patronage was appointed by Romulus, to unite the rich and poor together, in fuch manner, as that one might live without contempt, and the other without envy. This patronage was a tie as effectual as any confanguinity or alliance, and had a wonderful effect towards maintaining union and concord among the people for an interval of 600 years; during which time we find no dissensions or jealousies between the patrons and their clients, even in the times of the republic, when the populace frequently mutinied against those who were the most powerful in the city. But the condition of a client, in course of time, became little else but a moderate kind of slavery.

By degrees, the custom extended itself beyond Rome; and not only families, but cities, and entire provinces, even out of Italy, followed the example. Thus Sicily, *v. gr.* put itself under the clientela, or protection of Marcellus.

Lazius and Budæus refer the origin of fiefs and tenures to the patrons and clients of ancient Rome: but the difference is pretty considerable between the relation of vassals and their lords, and that of clients and their patrons. See Vassal.

The clients, beside the respect they bore their patrons, and the vote they gave them, were obliged to assist them in all affairs: and even to pay their ransom, if they should be taken prisoners in war, in case they were not able to do it of themselves; to contribute to the portions of their daughters, and to defray, in part, the charges of their public employments. They were never to accuse each other, or take contrary sides; and if either of them was convicted of having violated this law, the crime was equal to that of treason, and any one was allowed to kill the offender with impunity.

Client is now used for a party in a law-suit, who has turned over his cause into the hands of a counsellor, or solicitor, and who puts himself under their protection and defence. Clients are so called from their resemblance to those above-mentioned, who were dependant upon the ancient Roman orators. Those, indeed, practised *gratis*, for honour merely, or at most for the sake of gaining influence: and so likewise it is established with us (Davis, pref. 22. 1 Chan. Rep. 38), that a counsel can maintain no action for his fees; which are given, not as *locatio vel conductio*, but as *quiddam honorarium*; not as a salary or hire, but as a mere gratuity, which a counsellor cannot demand without doing wrong to his reputation: (Davis, 23); as is also laid down with regard to advocates in the civil law, (Ff. 11. 6. 1.), whose *honorarium* was directed by a decree of the senate not to exceed in any case 10,000 sesterces, or about 80*l.* of English money. (Tac. Ann. l. 11.) And, in order to encourage due freedom of speech in the lawful defence of their clients, and at the same time to give a check to the unseemly licentiousness of prostitute and illiberal men, (a few of whom may sometimes insinuate themselves even into the most honourable professions), it hath been holden that a counsel is not answerable for any matter by him spoken, relative to the cause in hand, and suggested in his client's instructions; although it should reflect upon the reputation of another, and even prove absolutely groundless: but if he mentions an untruth of his own invention, or even upon instructions, if it be impertinent to the cause in hand, he is then liable to an action from the party injured. (Cro. Jac. 90.) And counsel guilty of deceit or collusion are punishable by the statute Westm. 1 (3 Edw. I. c. 28.) with imprisonment for a year and a day, and perpetual silence in the courts:—a punishment still sometimes inflicted for gross misdemeanors in practice. (Raym. 376.) Blackst. Com. B. 111.

Clients. Gentlemen, who served in the French armies under the pennon of a chevalier, under the banner of a banneret, or under that of the advowée of some abbey.

CLIFF, Cliff-Regis, or King's-Cliff, in *Geography*, a town of England, in the county of Northampton, with a weekly market on Tuesdays; 8 miles S. of Stamford, and 88 N. of London.

Cliff, a village in Kent, in the lath of Aylesford, situate at the edge of the marshes which border on the Thames river, near the top of the chalk strata. The situation of the steeple of its church was determined in the government trigonometrical survey in 1799, by an observation from Gad's-hill station distant 19,967 feet; and another from Gravesend station distant 50,549 feet, and bearing 70° 49′ 7″ S.W. from the parallel to the meridian of Greenwich observatory: whence is deduced its latitude 51° 27′ 43″ N. and its longitude 29′ 50″ E.

CLIFFORD, George, in *Biography*, the third earl of Cumberland, a nobleman distinguished for his skill and enterprize in naval expeditions, was born at Brougham castle in Westmoreland in the year 1558. He received his college education at Peterhouse, Cambridge, under Whitgift, who was afterwards archbishop of Canterbury. The bent of his pursuits at this period was the study of mathematics, by which he was afterwards eminently qualified for the several great expeditions in which he engaged. He was likewise much addicted to athletic exercises, and is said to have excelled all his contemporaries in tilts, tournaments, and field sports. The first public business in which we find him engaged, was in 1586, when as a peer of the realm he sat in judgment upon Mary queen of Scots. In the same year he fitted out a small fleet, consisting of four vessels, for the South-sea, with a view either to maritime discoveries, or more probably that he might distinguish himself in injuring the enemies of his sovereign: his operations were, however, in this instance, chiefly confined to the eastern coast of South America, and he returned with little success. In the year 1588, the earl of Cumberland was among the number of those who signalized themselves by the destruction of the famous armada intended for the ruin of this country. The valour which he exhibited on this highly interesting and important occasion so far recommended him to the queen, that as a reward she gave him a commission to proceed to the South-seas, and lent him a vessel of her own for his admiral ship. In this and some subsequent expeditions during three following years, he was generally unfortunate. Not discouraged, however, by the want of that success which he had anticipated, he undertook, in 1592, another expedition with a fleet of his own: he first proceeded to the Azores, where, in conjunction with some other English ships, they attacked the Santa Cruz, a rich carrack, which the Spaniards set on fire, after they had put the most valuable part of its cargo on shore; but the English landed, and made themselves masters of it and of the town. The share of the prize-money which should have fallen to the earl of Cumberland, in this expedition, would have been very considerable, but from a series of unfortunate occurrences it was reduced to 36,000*l.* In 1593, he made another cruize, and took many valuable prizes: and in 1595 he built a vessel of 900 tons burden, which was the largest that had been sent to sea by any English subject; he at the same time fitted out three small ones, with a view of undertaking another expedition in which he was disappointed by the queen's mandate: his ships, however, pursued their voyage under a different commander, and were successful in capturing a number of vessels, some of which were richly laden. His last and most considerable expedition was in 1598, when he commanded nineteen ships; of these the principal one was his own great ship, to which the queen had given the name of "The Scourge of Malice." With this fleet he proceeded to the West Indies: he first touched at the Canaries, and then, after mustering all his force at the Virgin isles, he sailed to Porto Rico, the capital of which he attacked and captured, with its strong fort of Mora. This town being reckoned the key of the West-India

India islands, and a paffage to all the wealth on the continent of America, the noble earl refolved to keep poffeffion of it. For this purpofe he fent away the inhabitants to Carthagena, though he afferts that he was offered property to the amount of half a million fterling, to abandon this ftep. This expedition, though in many refpects highly fuccefsful, proved in the end very difaftrous. Before his return he loft more than 700 men, either by difeafe or the fword, befides feveral of his veffels by fhipwreck. The character of the earl of Cumberland's expeditions, of which he made eleven, will not bear to be feverely fcrutinized; they were rather of a predatory nature than calculated to improve the noble fcience of navigation. No difcoveries are recorded to render his name illuftrious as a philofopher, and no very important victories that could give him juft pretenfions to the title of hero, by which he was, in his own, and fome fucceeding ages, defignated. His adventures were neverthelefs of confiderable importance to the nation, as well by exciting and fupporting a fpirit of maritime enterprize, as by injuring and reducing the power of Spain. By thefe eleven voyages, and by building fhips, horfe-racing, tilting, and other expenfive exercifes, this nobleman is faid to have wafted more of his eftate than any of his anceftors. It ought not to be omitted that in the year 1592, he was elected knight of the garter: and in 1601, he was one of thofe who were fent with forces to reduce the earl of Effex to obedience. It appears alfo that he fat upon the earl's trial and made a feeble oppofition to the fentence paffed on him: faying, "that if he thought it would have availed, he would have demanded more time to deliberate on the fubject; that he deemed it fomewhat too fevere, and that any commander in chief might eafily incur a fimilar penalty." "But, however," added he, "in confidence of her majefty's mercy, I agree with the reft." The earl of Cumberland died at the Savoy in October 1605, and was buried at Skipton, Yorkfhire, where a fine monument was afterwards erected to his memory. He married Margaret, the third daughter of the earl of Bedford, by whom he had two fons, who died young, and a daughter, who was the celebrated countefs of Dorfet, Pembroke, and Montgomery. Biog. Brit. Hume's Hift.

CLIFFORTIA, in *Botany*, (named by Eichrodt in honour of George Clifford, a merchant at Amfterdam, the friend and patron of Linnæus, a catalogue of whofe garden was publifhed by him at Amfterdam in 1737, in a fplendid folio, under the title of "Hortus Cliffortianus"). Linn. Gen. 1133. Schreb. 1550. Juff. 337. Vent. 3. 334. Clafs and order, *diœcia polyandria*. Nat. Ord. *Tricoccæ*, Linn. *Rofaceæ*, Juff. Vent.

Gen. Ch. *Male. Cal.* Perianth three-leaved (three-cleft, Juff. Vent.) leaves egg-fhaped, acute, coriaceous, fpreading, deciduous. *Cor.* none. *Stam.* Filaments about thirty, capillary, erect, the length of the calyx; anthers didymous, oblong, obtufe, erect, compreffed. *Female. Cal.* Perianth three-leaved, equal, erect, fuperior, permanent; leaves acute, lanceolate. *Cor.* none. *Pift.* Germ oblong, inferior; ftyles two, filiform, long, plumofe; ftigmas fimple. *Peric.* Capfule oblong, nearly cylindrical, crowned with the calyx, two-celled. *Seeds* linear, one in each cell.

Eff. Ch. *Male.* Calyx three-leaved. Cor. none. Stamens about thirty. *Fem.* Calyx three-leaved, fuperior. Cor. none. Capfule two-celled. Seeds one in each cell.

All the known fpecies are perennial fhrubs from the Cape of Good Hope, and have either ternate or fimple leaves.

* *Leaves fimple.*

Sp. 1. C. *odorata*, Linn. jun. Supp. 431. Mart. 1. Lam. 8. "Leaves egg-fhaped, ferrated, ribbed, villous underneath." A fhrub, about three feet high, erect, but little branched; branches fimple, fomewhat pubefcent. *Leaves* alternate, on fhort petioles, obtufe, refembling thofe of mint; nearly an inch and half long, an inch broad; ftipules at the bafe of the leaf, membranous, femibifid, acute; villous as well as the petioles, withering. *Flowers* axillary, feffile. The younger Linnæus had feen only a plant with male flowers, which agreed with the other fpecies, though the habit of the plant is different. Found by Thunberg. 2. C. *ilicifolia*, Linn. Sp. Pl. 1. Mart. 2. Lam. 1. Ill. Pl. 827. fig. 1. Dill. Elth. tab. 31. fig. 35. "Leaves fomewhat heart-fhaped, toothed." A fhrub, two or three feet high, quite fmooth; branches alternate, diffufe, covered with fhort, fheathing, two-pointed ftipules. *Leaves* fmall, alternate, biennial, continuing green all the year, cartilaginous about the edge, placed near together, truncate-heart-fhaped, or roundifh, a little embracing the ftem, jointed on the hinder edge of the fheathing ftipule, fmooth, nerved, edged with rather diftant fpinous teeth. *Flowers* green, lateral, axillary, folitary, feffile. Cultivated in Chelfea garden, 1714, flowering in June, July, and Auguft. 3. C. *cordifolia*, Lam. 2. "Leaves heart-fhaped, quite entire, embracing the ftem; upper ones toothed." Nearly allied to the preceding; communicated to La Marck by Sonnerat. 4. C. *rufcifolia*, Linn. Sp. Pl. 2. Mart. 3. Lam. 3. Ill. Pl. 827. fig. 2. (Frutex æthiopicus, &c. Pluk. Alm. 159. tab. 297. fig. 2.) "Leaves lanceolate, quite entire." A fhrub, about two feet high, thickly branched; branches alternate, compound, afcending, afh-coloured, and fmooth near the bottom, brown and tomentous above; little branches fhort, covered with lanceolate, acuminate, fheathing ftipules, leafy only at the end. *Leaves* fmall, numerous, growing clofe together, feffile, terminated by a fharp, and fometimes bifid fpine, fmooth and fhining above, nerved and villous underneath. *Flowers* at the ends of the little branches, in roundifh fpikes, intrenched in the leaves; bractes fmaller than the leaves, involving each flower, trifid, hirfute on the outfide, fpinous, with a fharp membranous hairy leaflet near the bafe, on each fide; germ egg-fhaped, obtufe, alternated at the bafe, rather gibbous, ftreaked and angular. Introduced by Maffon in 1786; communicated alfo to La Marck by Maffon. 5. C. *graminea*, Linn. jun. Supp. 429. Mart. 5. Lam. 0. "Leaves enfiform, flightly ferrated; petioles dilated, terminated by two ftipule-fhaped awns." A fhrub. *Stems* feveral, two feet high, fcarcely branching, ftriated, covered with leaves. *Leaves* growing near together, erect, convolute, fmooth, ftriated, acute; petioles broad, connected with the leaves by a joint; the edges elongated into awl-fhaped, erect divifions. Found by Thunberg. 6. C. *ferruginea*, Linn. jun. Supp. 429. Mart. 4. (C. berberidifolia, Lam. 9.) "Leaves lanceolate, fetaceous-ferrated," Linn. jun. "Stem fmooth; branches alternate, very fhort, leafy; leaves fomewhat lanceolate, fetaceous-ferrated, crowded," Lam. *Stems* like thofe of knot-grafs, filiform, ufually proftrate, even furface, and branching; branches fhort, ferruginous, herbaceous. *Leaves* alternate, on fhort petioles, ftriated, acute, naked; ferratures fetaceous, unarmed; ftipules two-cleft, ferruginous, fcarious. *Flowers* axillary, feffile, trifid; filaments capillary, long; anthers egg-fhaped. La Marck doubts whether this be the fame plant with his berberidifolia, as there is no mention of the crowded leaves, and the abundant hairs on the ftipulary fheaths, which appear in his fpecimens. Found by Sparman. 7. C. *polygonifolia*, Linn. Sp. Pl. 3. Mart. 6. Lam. 4. "Leaves linear, hairy." An under-fhrub, about a foot high, much branched, villous; branches flender, cylindrical, pubefcent, leafy. *Leaves* very fmall, linear, acute, quite entire, but undulated, apparently in alternate fafcicles, but really growing three together

together upon each small sheath. *Capsules* of an even surface, smaller than grains of wheat. 8. C. *filifolia*, Linn. jun. 430. Mart. 7. Lam. 17. "Leaves filiform, triquetrous, smooth, quite entire." Found by Thunberg. 9. C. *teretifolia*, Linn. jun. Supp. 430. Mart. 17. Lam. 18. "Leaves fascicled, cylindrical, incurved, smooth, entire." 10. C. *ericæfolia*, Linn. jun. Supp. 430. Mart. 18. Lam. 19. "Leaves fascicled, cylindrical, furrowed, smooth." The last three species greatly resemble each other. They were all found by Thunberg, and were introduced into England by Masson, 1787. 11. C. *cuneata*, Hort. Kew. 3. 413. Mart. 19. "Leaves wedge-shaped, serrated at the end." Introduced by Masson, 1787.

** *Leaves compound.*

12. C. *crenata*, Linn. jun. 430. Mart. 8. Lam. 12. "Leaves binate, orbicular, crenulate." *Leaves* alternate, sessile, smooth, the size of a finger-nail. *Flowers* axillary, solitary, trifid. Found by Thunberg. 13. C. *pulchella*, Linn. jun. Supp. 430. Mart. 19. Lam. 13. "Leaves binate, orbicular, quite entire." *Leaves* connivent, forming a cavity which protects the flowers, beautifully adorned on the outside with radiating nerves. Found by Thunberg. 14. C. *trifoliata*, Linn. Sp. Pl. 4. Mart. 10. Lam. 5. (myrica. Hort. Cliff. 456. 6. Thymelææ forte affinis; Pluk. Alm. 367. tab. 319. fig. 4.) "Leaves ternate; intermediate leaflet three-toothed." *Stems* slender, woody, procumbent, silky, with hairs, sending out slender branches on every side. *Leaves* sessile, hairy; side leaflets lanceolate; middle one broader. *Flowers* axillary, on short peduncles. There is a variety with smaller, linear-lanceolate leaflets. Cultivated by Miller before 1759; flowering in July and August. 15. C. *sarmentosa*, Linn. Mant. 299. Mart. 11. Lam. 6. "Leaves ternate, linear, villous." *Stem* four feet high, shrubby, filiform, sarmentous; branches alternate, short, simple, cylindrical, pubescent. *Leaves* alternate, almost sessile, nearly equal, very narrow, unarmed; petiole short, stipular, membranous, dilated, emarginate, naked. *Flowers* white, axillary, solitary, sessile. 16. C. *strobilifera*, Murray, Syst. 893. (cedrus conifera; Pluk. Alm. 91. tab. 275. fig. 2.) "Leaves ternate, linear, acute, even-surfaced." A shrub. *Branches* slender, cylindrical, smooth. *Leaves* sessile, carinated, on a short sheathing petiole; stipular sheaths permanent, after the leaves have fallen, nearly egg-shaped, scarious, with two teeth, smooth. The sessile, lateral, scaly, egg-shaped cones which occur on the branches, are supposed by Linnæus to be gals, and not fruit. Jussieu doubts, whether it be really a cliffortia. La Marck's specimens are beset with cones of different sizes, without any appearance of fructification. 17. C. *obcordata*, Linn. jun. Supp. 429. Mart. 13. Lam. 11. "Leaves ternate; leaflets roundish, middle one inversely heart-shaped." An erect, low shrub, with distich branches. *Leaves* small, sessile, inversely egg-shaped, nerveless, very obtuse, quite entire, smooth, resembling those of purslane (peplis), often binate. *Flowers* axillary, sessile, not longer than the leaves. 18. C. *ternata*, Linn. Supp. 430. Mart. 14. Lam. 16. "Leaves ternate; leaflets entire, hairy." A shrub, very distinct from the other species. *Leaflets* small, ovate-lanceolate. Found by Thunberg. 19. C. *juniperina*, Linn. jun. 430. Mart. 15. Lam. 15. "Leaves ternate, triquetrous, awl-shaped, crowded." A shrub, with the habit of a juniper, three feet high, much branched. *Leaves* on a broadish, very short, scarcely perceptible peduncle; leaflets acerose, linear, channelled, mucronate, somewhat serrated. *Flowers* axillary, sessile. 20. C. *falcata*, Linn. jun. Supp. 431. Mart. 16. Lam. 14. "Leaves ternate, linear, falcate, smooth." A shrub, about a foot high, erect, branched, stiff and straight. *Leaves* resembling those of C. sarmentosa, but smooth, often three from each bud; leaflets rather acute, incurved. Found by Thunberg.

Propagation and culture. C. ilicifolia is easily propagated by cuttings in any of the summer months. These should be planted in small pots, filled with light earth; when they have taken root, they should be gradually exposed to the open air, and when they have gained some strength, may be transplanted separately into small pots, and placed with other hardy kinds of exotic plants, in a sheltered situation, till October; they should then be placed under a common hot-bed frame, or removed into the green-house, but should enjoy the free air, whenever the season is mild. When the plants advance in height, their stem and branches will require support, they will then thrive with the same treatment as myrtles, and other hardy green-house plants, but must have little water in winter. C. trifoliata is equally hardy. C. ruscifolia is more tender, and more difficult to propagate.

CLIFT, in the *Manege*, a deficiency in the new, soft, and rough uneven hoof that grows in horses feet, upon the hoof cast. It is also called *chink*, *crack*, or *chop*, and by the French *avalure*. See CLEFT.

CLIFTS, in timber. See TIMBER.

CLIFTON, FRANCIS, in *Biography*, doctor in medicine, received his education in the university of Oxford, which completed, he came to London, and about the year 1730, he was admitted a fellow of the College of Physicians, and soon after of the Royal Society. In 1732 he published "The State of Physic, ancient and modern, briefly considered, with a Plan for improving it," 8vo. The first part of the volume contains a compendium of the history of physic, written in the manner of Friend's history, but not equally correct. He shews a marked partiality for empirics, amongst whom he places Hippocrates, and censures Galen, for attempting to found his practice on ratiocination. He proposes a law, obliging physicians and surgeons to keep registers of the cases they attend, which are to be sent to an institution, to be formed for the purpose. The accounts are to contain simply descriptions of the diseases with the remedies employed in their cure. He had before, *viz.* in 1731, published, "A plain and sure Way of practising Physic," 8vo. He recommends the use of the warm-bath in the small-pox, and condemns the practice of giving purges in that complaint, which had been recommended by Dr. Friend. He also translated "Hippocrates de Aere, Aquis et Locis," with the title of Hippocrates on air, water, and situations, upon epidemical diseases, and upon prognostics in acute cases, illustrated with notes, and added a translation from Thucydides, of the account of the plague at Athens, 8vo. 1734. Boerhaave Methodus Studii Medici.

CLIFTON, in *Geography*, a village of Gloucestershire, famous for its medicinal springs, called "Bristol hot-wells," supposed to be one of the pleasantest villages in the kingdom; 1 mile from Bristol. See BRISTOL.

The situation of a wind-mill in a conspicuous place in this parish, sometimes called Clifden wind-mill, was determined it the government trigonometrical survey in 1797, by an observation from Dundry station, distant 12,860 feet, and bearing 9° 52′ 50″ S.W. from the parallel to the meridian of Black-down station; and another from Lansdown station, distant 51,725 feet; whence is deduced its latitude 51° 25′ 53″ N. and its longitude from Greenwich 2° 37′ 26″ W. or 10^m 29ˢ.7 in time.

CLIFTON, a village near the south-eastern extremity of the west-riding of Yorkshire, in the hundred of Strafford; which parish will probably be hereafter often noted, on account of a remarkable eminence therein, called Beacon Hill, on on which a station was chosen in 1801, in the government trigonometrical survey, and where, in 1802, the curious *zenith-sector*, (see that article), the last work of that celebrated artist Mr. Jesse Ramsden, was used for determining the latitude of this station, as the northernmost point in the terrestrial arc of the meridian, of whose measurement a detailed account has been published by major William Mudge in the Philosophical Transactions for 1803; being the first attempt at the measurement of an arc of the meridian in Britain of any considerable length, since the days of our countryman Norwood, about the year 1635. Clifton station was chosen, on account of its falling almost exactly on the meridian of the station at Dunnose, in the Isle of Wight, which had been fixed on, as the south end of the British meridional arc to be measured; and also on account of the fen called the Isle of Axholme, in Lincolnshire, lying within full view of this station, and presenting an eligible situation for measuring a base of verification; and whereon, in the part called Misterton-carr, a line 26342.7 feet in length, terminated by points called Misterton north and south stations, was measured in June and July, 1801, on the level surface of the fen, by means of the curious steel chains and apparatus of Ramsden's construction, which were used in the re-measurement of the first base on Hounslow-heath in 1791; this Misterton base being situate about 35 feet above the level of half tide in the ocean, at the mouth of the Humber river.

In August 1801, one of Ramsden's great *theodolites* (see that article) was erected on Clifton station, the horizontal angles between Misterton north and Misterton south stations, Gringley station and Heathersedge, or Lords'-seat station, respectively, were repeatedly observed; and thirteen observations of the pole-star, when at its greatest elongations from the meridian, were carefully made; whence, Gringley station was found to bear 76° 17′ 25″ S.E. from the meridian of Clifton station, distant by calculation 75,068 feet; Misterton north and south stations, and Heathersedge station being 64,462, 73,322, and 92,227 feet respectively distant. The spire of Loughton en le Morthen church being found to bear only 1° 56′ 8″ W. of the south meridian of Clifton station, the spindle of its weathercock was made use of as a meridian mark, for adjusting the zenith-sector, when the same was erected on the 19th of July, 1802, on a spot $3\frac{1}{2}$ feet south of the station at Clifton, by setting off that arc on the azimuth circle of the instrument; between the above date and the 19th of August, the following zenith distances of stars were carefully observed as they passed the meridian, *viz.* 15 of β Draconis, the mean of which gave 1° 0′ 17″.84 S.; 15 of γ Draconis, which gave 1° 56′ 26″.64 S.; 9 of 45 *d* Draconis, which gave 3° 26′ 22″.92 N.; 11 of 46 *c* Draconis, which gave 1° 53′ 6″.24 N.; 9 of 51 Draconis, which gave 0° 21′ 38″.12 N.; 6 of μ Draconis, which gave 1° 16′ 38″.20 N.; 3 of 16 Draconis, wich gave 0° 7′ 51″.25 S.; 14 of 1 κ Cygni, which gave 0° 27′ 0″.32 S.; 12 of 10 ι Cygni, which gave 2° 8′ 42″.22 S.; one of γ Ursæ, which gave 1° 20′ 13″.53 N.; 5 of η Ursæ, which gave 3° 9′ 6″.98 S.; 5 of ζ Ursæ, which gave 2° 30′ 10″.37 N.; 8 of 85 ι Herculis, which gave 7° 20′ 24″.98 S.; 4 of 52 Herculis, which gave 7° 7′ 25″.52 S.; 6 of τ Herculis, which gave 6° 40′ 1″.29 S.; 5 of α Persei, which gave 4° 18′ 36″.02 S.; and 5 of Capella, which gave 7° 40′ 25″.66 S.

Comparing these, with 10 of these stars' zenith distances, observed by help of this zenith-sector at Greenwich royal observatory (for the remaining star, 15 ι Herculis, seems either to have been mistaken in the observation for some other small star, or its z.d. to have been wrong observed near 1′) we get 1° 58′ 52″ for the difference of latitude between Greenwich and Clifton; whence, the latitude of Clifton station is found 53° 27′ 32″, and its longitude appears to be 1° 12′ 23″.6 W. of Greenwich. The elevation of Clifton station above the level of the sea is not given, but we are told that from thence the apparent depression of Gringley station was 18′ 47″, and the apparent elevation of Heathersedge station 29′ 12″. The singular result of the measurement of the different parts of the arc between Dunnose and Clifton, wherein the lengths of degrees decrease instead of increasing, as they ought to do on a flattened ellipsoid, presents matter of curious investigation, and may, perhaps, furnish some data for ascertaining the arrangement of the gravitating masses of which the earth is composed. We wish that the zenith-sector were used at more of the intermediate stations, in order to discover more exactly the law of decrease in the British degrees.

CLIKAPOTIN, a town of Poland, in the palatinate of Volhynia; 72 miles E. of Lucko.

CLIMA, in *Ancient Geography*, a term used under the Lower Empire for a division of provinces.

CLIMA *Anatolicum*, an episcopal see of Asia, in Phœnicia, near mount Libanus, under the metropolis of Edessa. —— *Anatolis*, an episcopal see of Asia, in Arabia. —— *Anzitines*, a place of Asia, in the Fourth Armenia. —— *Asianicæ*, a place of Asia in the same province. —— *Bilabitensis*, a place of the same province. —— *Digesenes*, a place in the same province. —— *Gablanim*, or *Galanis*, an episcopal see of Asia, under the metropolis of Scythopolis. —— *Garenes*, an episcopal see of Asia, in the 4th Armenia. —— *Imbrudorum*, an episcopal see of Asia, in the Phœnicia of Libanus, under the metropolis of Edessa. —— *Magludorum*, an episcopal place in Asia, in the Phœnicia of Libanus, under the metropolis of Edessa. —— *Mamuzurarum*, an episcopal see of Asia, in the 4th Armenia. —— *Mesticon*, one of the five towns of the prefecture of Thrace. —— *Orientalium* et *Occidentalium*, an episcopal see of Arabia. —— *Orzianices*, an episcopal see of Asia, in the 4th Armenia. —— *Sophenes*, an episcopal place of Asia, in the same province.

CLIMACÆ, a place in the island of Eubœa, mentioned by Hesychius.

CLIMACIDES, among the Greeks, were women servants who assisted their mistresses to get on horseback, by serving as steps for them to ascend by.

CLIMACTERIC, *Annus* CLIMACTERICUS, a critical year, or period, in a man's age, wherein, according to astrologers, there is some very notable alteration to happen in the body; and a person is exposed to great danger of death. The word comes from κλιμακτηρ, or κλιμακτηρικος, of κλιμαξ, κλιμακος, *scala*; q. d. *by a scale*, or *ladder*.

The first climacteric is, according to some, the seventh year of a man's life; the rest are multiples of the first, as 14, 21, 49, 56, 63, and 84; which two last are called the *grand climacterics*, and the dangers here are supposed more imminent.

The opinion has a great deal of antiquity on its side. Aulus Gellius says, it was borrowed from the Chaldeans; who might probably receive it from Pythagoras, whose philosophy turned much on numbers; and who imagined an extraordinary virtue in the number 7.

Marc. Ficinus gives us the foundation of the opinion: he tells us, there is a year assigned for each planet to rule over the body of man, each in his turn: now Saturn being the most maleficent planet of all, every seventh year, which falls to his lot, becomes very dangerous; especially those of 63 and 84, when the person is already advanced in years.

Some

Some hold, according to this doctrine, every ſeventh year an eſtabliſhed climacteric; but others only allow the title to thoſe produced by the multiplication of the climacterical ſpace by an odd number, 3, 5, 7, 9, &c. Others obſerve every ninth year as a climacteric.

Hevelius has a volume under the title of Annus Climactericus, deſcribing the loſs he ſuſtained in the burning of his obſervatory, &c. which it ſeems happened in his firſt *grand climacteric*.

Suetonius ſays, Auguſtus congratulated his nephew upon his having paſſed his firſt grand climacteric, whereof he was very apprehenſive.

Some pretend that the climacteric years are alſo fatal to political bodies; which perhaps may be granted, when it is proved that they are ſo to natural ones.

Authors on this ſubject, are Plato, Cicero, Macrobius, Aulus Gellius, among the ancients; Argol, Magirus, and Salmaſius, among the moderns. And St. Auguſtine, St. Ambroſe, Beda, and Boetius, countenance the opinion.

CLIMATARCHÆ, Κλιματαρχαι, were governors of provinces to the Greek emperors.

CLIMATE, Clima, or Clime, in *Geography*, a part of the ſurface of the earth, bounded by two circles parallel to the equator, and of ſuch a breadth, as that the longeſt day in the parallel near the pole exceeds the longeſt day in that next the equator by ſome certain ſpace; *viz.* half an hour, an hour, or a month.

The word comes from κλιμα, *inclinamentum*, an *inclination;* becauſe the difference of climates ariſes from the different inclination or obliquity of the ſphere.

The beginning of the climate is the parallel circle wherein the day is the ſhorteſt; and the end of it is that wherein the day is the longeſt. The climates therefore are reckoned from the equator to the pole; and are ſo many bands, or zones, terminated by lines parallel to the equator: though, in ſtrictneſs, there are ſeveral climates in the breadth of one zone. Each climate only differs from its contiguous ones, in that the longeſt day in ſummer is longer or ſhorter, *e. g.* by half an hour, in the one place than in the other.

As the climates commence at the equator, the firſt climate, at its beginning, has its longeſt day preciſely twelve hours long; at its end, twelve hours and an half; the ſecond, which begins where the firſt ends, *viz.* at twelve hours and an half, ends at thirteen hours; and ſo of the reſt, as far as the polar circles, where thoſe, which the geographers call *hour-climates* terminate, and *month climates* commence.

As an *hour-climate* is a ſpace compriſed between two parallels of the equator, in the firſt of which the longeſt day exceeds that in the latter by half an hour; ſo the *month climate* is a ſpace terminated between two circles parallel to the polar circles, whoſe longeſt day is longer or ſhorter than that of its contiguous one by a month, or thirty days.

The ancients, who confined the climates to what they imagined the habitable parts of the earth, only allowed of ſeven. The middle of the firſt northern climate they made to paſs through Meroe; the ſecond through Syene; the third through Alexandria; the fourth through Rhodes; the fifth through Rome; or, according to others, through the Helleſpont; the ſixth through the mouth of the Boryſthenes; and the ſeventh through the Riphæan mountains. The ſouthern part of the earth being then very little known; the ſouthern climates received their names from the northern ones, to which they did in ſuch a manner correſpond, that they were as far diſtant from the equator ſouthward as the others were northward. The moderns, who have failed farther toward the poles, make thirty climates on each ſide: and in regard the obliquity of the ſphere makes a little difference in the length of the longeſt day; inſtead of half an hour, ſome of them only make the difference of climates a quarter.

A parallel is ſaid to paſs through the middle of a climate, when the longeſt day in that parallel differs a quarter of an hour from the longeſt day in either of the extreme parallels that bound the climate; this parallel does not divide the climate into two equal parts, but the part neareſt to the equator is larger than the other; becauſe the farther we go from the equator, the leſs increaſe of latitude will be ſufficient to increaſe the length of the longeſt day, a quarter of an hour; in the middle parallel of the firſt climate the longeſt day is 13 hours; in the middle of the ſecond climate, 13 hours and a half; in the middle of the third, 14 hours, &c. We may obſerve that every climate has three parallels, which mark the beginning, the middle, and the end of it; and that the parallel which marks the end of every preceding climate is the beginning of that which is immediately ſubſequent. Some of the ancients divide the earth by theſe parallels, and ſometimes by a parallel, they do not mean a mere linear circle, but a ſpace of ſome breadth; in which ſenſe a parallel is the ſame as half a climate, and ſhews the difference of a quarter of an hour in the length of the longeſt day.

In fixing the climates, there ordinarily is no regard had to the refraction.

Varenius gives us a table of thirty climates; but without any regard to the refraction. Ricciolus furniſhes a more accurate one, wherein the refractions are allowed for: an abſtract of which follows:

A Table of Climates.

Middle of Climate.	Longest Day.		Latitude.		Climates.	Longest Day.		Latitude.		Middle of Climate.	Latitude.		N. Lat. Continual Day.	N. Lat. Continual Night.	S. Lat. Continual Day.	S. Lat. Continual Night.

VII	15	30	44	42	XIV	24	0	65	54							

Vulgarly,

Vulgarly, the term climate is beftowed on any country or region differing from another, either in refpect of the feafons, the quality of the foil, or even the manners of the inhabitants; without any regard to the length of the longeft day.

Abulfeda, an Arabic author, diftinguifhes the firft kind of climates by the term *real climates;* and the latter by that of *apparent climates*.

The temperature of any climate, although it fhould feem to depend principally on latitude, or diftance from the equator, and the confequent more vertical or more oblique incidence of the rays of the fun, is, neverthelefs, very materially affected by a variety of collateral circumftances; fuch as the fituation, whether it be high or low, the nature of the foil, the extent of the continent, the vicinity of mountains, forefts, marfhes, lakes, and feas, and the direction of the winds. The influence of thefe is, however, on various accounts lefs confiderable in the greater part of the ancient continent than in that of America, where the rigour of the frigid zone extends over half of that which fhould be temperate by its pofition; and where lands, fituated in the fame parallel with the moft fertile and beft cultivated provinces in Europe, are chilled with perpetual frofts, which almoft deftroy the power of vegetation. Thus, Newfoundland, part of Nova Scotia, and Canada, lie in the fame parallel with France; and yet, in every part of thefe the water of the rivers is frozen during winter to the thicknefs of feveral feet; the earth is covered with fnow as deep; almoft all the birds fly during that feafon, from a climate where they could not live. The country of the Efquimaux, part of Labrador, and the countries on the fouth of Hudfon's bay, are in the fame parallel with Great Britain; and yet, in all thefe the cold is fo intenfe, that even the induftry of the Europeans has not attempted cultivation. As we proceed to thofe parts of America, which lie in the fame parallel with provinces of Afia and Africa, poffeffing genial warmth, eminently favourable to life and vegetation, the dominion of cold prevails, and winter, during its fhort period, often reigns with extreme feverity. In advancing along the American continent into the torrid zone, the excefs of its fervour will be found in a confiderable degree mitigated by the cold of this continent. While the negro on the coaft of Africa is fcorched with unremitting heat, the inhabitant of Peru breathes a mild and temperate air, and is fhaded under a canopy of grey clouds, which intercepts the fierce beams of the fun, without obftructing his friendly influence. Along the eaftern coaft of America, the climate, though more fimilar to that of the torrid zone in other parts of the earth, is, neverthelefs, confiderably milder than in thofe countries of Afia and Africa which lie in the fame latitude. If, from the fouthern tropic, we continue our progrefs to the extremity of the American continent, we meet with frozen feas, and countries that are barren and fcarcely habitable for cold, fooner than in the north. M. de Paw, in his "Recherches Philofophiques fur les Americains," cited by Dr. Robertfon, (Hift. Amer. vol. ii. p. 472.) fuppofes, that the difference in heat between America and the old continent is equal to 12 degrees, and that a place 30° from the equator, in the latter, is as warm as one fituated 18° from it in the former. Dr. Mitchell alfo, after obfervations carried on during 30 years, contends, that the difference is equal to 14 or 15 degrees of latitude; or that it is as hot in the countries of the old continent at 29 or 30 degrees, as in the countries of the new continent, which are at 15 degrees. The abbé Clavigero, in his "Hiftory of Mexico," (p. 263.) difputes thefe facts; and he fays, that as there are many countries in America more cold than others of the old continent equi-diftant from the equator, there are alfo others more hot. Agra, the capital of Mogul, and the port of Loretto in California, are nearly in the fame latitude, and ftill the heat of that Afiatic city is not comparable to that of the American port. Hüe, the capital of Cochin-China, and Acapulco, are almoft equidiftant from the equator, and yet the air of Hue is cool, in comparifon of that of Acapulco. M. de Paw has alfo affirmed, that in the centre of the torrid zone the liquor of the thermometer does not rife to fo great a height as it does in Paris in the greateft heat of fummer; to which Clavigero replies, that if that were true, the difference between the American and European climates would not be only 12°, as M. de Paw would make it, but 49°, that is, as much as the difference of latitude between the centre of the torrid zone and Paris. It is true, fays the abbé, that according to the obfervations made in Quito, compared with thofe made in Paris, the heat of that equinoctial city never equals that of Paris in the fummer; but it is equally certain that, according to the obfervations made by the fame academicians with the fame thermometers, in the city of Carthagena, which is not the centre of the torrid zone, but ten degrees from it, the ufual heat of this city is equal to the greateft heat of Paris, agreeably to the teftimony of Ulloa, one of the obfervers. We fhall here add, as the refults of obfervations of M. de Paw, that the climate of America is not fo various as that of Europe; and, of courfe, that the inhabitants of the New World are not, like thofe of the greater part of Europe, obliged to endure the alternate extremes of exceffive cold and intolerable heat.

Thofe who maintain that the climate of America is extremely different from that of the ancient continent enumerate a variety of caufes that have combined to produce this difference. Although the utmoft extent of America towards the north be not yet difcovered, it is allowed that it advances much nearer to the pole than either Europe or Afia. The latter have large feas to the north, which are open during part of the year; and even when covered with ice, the wind that blows over them is lefs intenfely cold than that which blows over land in the fame high latitudes. But in America the land ftretches from the river St. Lawrence towards the pole, and fpreads out immenfely to the weft. A chain of enormous mountains, covered with fnow and ice, runs through all this dreary region. The wind, in paffing over fuch an extent of high and frozen land, acquires a piercing keennefs, which it retains in its progrefs through warmer climates, and is not entirely mitigated until it reach the gulf of Mexico. Over all the continent of North America, a north-wefterly wind and exceffive cold are fynonymous terms. Even in the moft fultry weather, the moment that the wind veers to that quarter, its penetrating influence is felt in a tranfition from heat to cold, no lefs violent than fudden. To this powerful caufe we may afcribe the extraordinary dominion of cold, and its violent inroads into the fouthern provinces in that part of the globe. Befides, in that portion of the American continent which lies between the tropics, the wind blows in an invariable direction from eaft to weft. As this wind holds its courfe acrofs the ancient continent, it arrives at the countries which ftretch along the weftern fhore of Africa, inflamed with all the fiery particles which it hath collected from the fultry plains of Afia, and the burning fands in the African deferts. Accordingly, the coaft of Africa is the region of the earth which feels the moft fervent heat, and is expofed to the unmitigated ardour of the torrid zone. But this fame wind which brings fuch an acceffion of warmth to the countries lying between the river of Senegal and Cafraria, traverfes the Atlantic ocean, before it reaches the American fhore. In its paffage over this vaft body of water it is cooled, and is felt as a refrefhing gale along the coaft of

Brasil and Guiana, rendering these countries, which are reckoned among the warmest in America, temperate, when compared with those which lie opposite to them in Africa. As this wind advances in its course across America, it meets with immense plains, covered with impenetrable forests, or occupied by large rivers, marshes, and stagnating waters, where it can recover no considerable degree of heat. At length it arrives at the Andes, which run from north to south through the whole continent. In passing over these elevated and frozen summits, it is so thoroughly cooled, that the greater part of the countries beyond them scarcely feels the ardour to which they seem exposed by their situation. Acosta appears to have been the first philosopher, who endeavoured to account for the different degrees of heat in the old and new continents, by the agency of the winds which blow in each. M. de Buffon has adopted this theory and embellished it by his descriptive eloquence; it has also been illustrated by later writers, in their inquiries concerning the temperature of various climates, as we shall find in the sequel of this article. Professor Robison furnished the elegant and popular historian of America with a variety of observations, elucidating this theory. To this purpose he observes, that, when a cold wind blows over-land, it must in its passage rob the surface of some of its heat; and thus the coldness of the wind is abated. But continuing to blow in the same direction, it will, by degrees, pass over a surface already cooled, and lose no degree of its keenness; and advancing over a large tract of land, it will occasion the severity of intense frost. If the same wind be supposed to blow over an extensive and deep sea, the superficial water must be immediately cooled to a certain degree, and the wind proportionably warmed. But the superficial and colder water becoming specifically heavier than the warmer water below it, descends; the warmer supplies its place, which, being cooled in its turn, continues to warm the air which passes over it, or to diminish its cold. This change of the superficial water, (and successive ascent of that which is warmer, and consequent successive abatement of coldness in the air,) is aided by the agitation caused in the sea by the mechanical action of the wind, and also by the motion of the tides. By this process, the rigour of the wind will continue to decrease until the whole water is so far cooled, that the water on the surface is no longer removed from the action of the wind, fast enough to hinder it from being arrested by frost. Whenever the surface freezes, the wind is no longer warmed by the water from below, and it goes on with undiminished cold. These principles serve to explain the severity of winter frosts in extensive continents; their mildness in small islands; and the superior rigour of winter in those parts of North America, with which we are best acquainted. In the N.W. parts of Europe, the severity of winter is mitigated by the west winds, which usually blow in the months of November, December, and part of January. On the other hand, when a warm wind blows over land, it heats the surface, which must therefore cease to abate the fervour of the wind. But, the same wind, blowing over water, agitates it, brings up the colder water from below, and thus is continually losing some of its own heat. After all, the great power of the sea to mitigate the heat of the wind or air passing over it, proceeds from the following circumstance; that on account of the transparency of the sea its surface cannot be heated to a great degree by the sun's rays; whereas the ground, subjected to their influence, very soon acquires great heat. When, therefore, the wind blows over a torrid continent, it is soon raised to a heat almost intolerable; but during its passage over an extensive ocean, it is gradually cooled; so that on its arrival at the farthest shore, it is again fit for respiration. These principles will account for the sultry heat of large continents in the torrid zone; for the mild climates of islands in the same latitude; and for the superior warmth in summer which large continents, situated in the temperate or colder zones of the earth enjoy, when compared with that of islands. The heat of a climate depends not only upon the immediate effect of the sun's rays, but on their continued operation, on the effect which they have formerly produced, and which remains for some time in the ground. Thus the day is warmest about two in the afternoon, the summer warmest about the middle of July, and the winter coldest about the middle of January.

The temperate climate in the equatorial parts of America is greatly owing to the forests which cover the country, and hinder the sun-beams from heating the ground; the ground, not being heated, cannot heat the air; and the leaves, which receive the rays intercepted from the ground, have not a mass of matter sufficient to absorb heat enough for the purpose. Besides, it is a known fact, that the vegetative power of a plant occasions a perspiration from the leaves, in proportion to the heat to which they are exposed; and from the nature of evaporation, this perspiration produces a cold in the leaf proportional to the perspiration. Thus the effect of the leaf in heating the air in contact with it is prodigiously diminished. See also Dr. Williamson's Observations on the effects of the agency of winds in reference to the temperature of different climates, in the first volume of the "Transactions of the American Philosophical Society," p. 272, &c. For a further account of the causes that produce a change in the temperature of the air; see the article *Temperature of the* ATMOSPHERE.

But to return from this digression on the effect of winds: We may observe that in the other provinces of America, from Terra Firma westward to the Mexican empire, the heat of the climate is tempered, in some places, by the elevation of the land above the sea; in others, by their extraordinary humidity; and in all, by the enormous mountains scattered over this part. The islands of America, in the torrid zone, are either small or mountainous, and are fanned alternately by refreshing sea and land breezes.

The causes of the extraordinary cold that prevails towards the southern limits of America, and in the seas beyond it, cannot be ascertained in a manner equally satisfactory. It was long supposed, that a vast continent, distinguished by the name of "Terra Australis Incognita," lay between the southern extremity of America and the Antarctic pole. The same principles which account for the extraordinary degree of cold in the northern regions of America were adopted in order to explain that which is felt at Cape Horn, and the adjacent countries. The immense extent of the southern continent, and the large rivers which it poured into the the ocean, were admitted by philosophers as causes sufficient to occasion the unusual sensation of cold, and the still more uncommon appearances of frozen seas in that region of the globe. But as such a continent is imaginary, and the space supposed to be occupied by it is an open sea, new conjectures must be formed with respect to the causes of a temperature of climate, so extremely different from that which we experience in countries removed at the same distance from the opposite pole. Of the extraordinary degree of cold, that occurs in southern latitudes, many instances are recorded. In lat. 48° some French voyagers, in 1739, found islands of floating ice; and a considerable degree of cold was experienced in lat. 44°. Dr. Halley found ice in lat. 59°. Commodore Byron, in lat. 50° 33′ S. of the coast of Patagonia, on the 15th of December, nearly midsummer in that part of the globe, compares the climate to that of England in the middle of winter.

When

When Mr. (fir Jofeph) Banks and his companions landed on Terra del Fuego, in the bay of Good Succefs, lat. 55°, Jan. 16 correfponding to July in our hemifphere, two of his attendants died in one night of extreme cold, and the whole party was in great danger of perifhing. On the 14th of March the mountains were covered with fnow. Capt. Cook, in his voyage towards the S. pole, expreffes his furprife, that an ifland of no greater extent than 70 leagues in circuit, between the latitudes of 54° and 55°, fhould in the very height of fummer be in a manner wholly covered many fathoms deep with frozen fnow; but more efpecially the S. W. coaft. The very fummits, he fays, of the lofty mountains were cafed with fnow and ice; but the quantity that lay in the vallies is incredible; and at the bottom of the bays, the coaft was terminated by a wall of ice of confiderable height. The moft obvious and probable caufe of the fuperior degree of cold, towards the fouthern extremity of America, feems to be the form of the continent there. Its breadth gradually decreafes as it ftretches from St. Antonio fouthwards, and from the bay of St. Julian to the ftraits of Magellan its dimenfions are much contracted. On the eaft and weft fides, it is wafhed by the Atlantic and Pacific oceans. From its fouthern point an open fea probably extends to the Antarctic pole. In whichever of thefe directions the wind blows, it is cooled before it approaches the Magellanic regions, in paffing over a great body of water; nor is the land there of fuch extent that it can recover any confiderable degree of heat in its progrefs over it. Thefe circumftances concur in rendering the temperature of the air in this diftrict of America more fimilar to that of an infular than to that of a continental climate, and hinders it from acquiring the fame degree of fummer heat, with places in Europe and Afia, in a correfponding northern latitude. The north wind is the only one that reaches this part of America, after blowing over a great continent; and this wind, though it blows over land, does not bring to the fouthern extremity of America, which is properly the termination of the immenfe ridge of the Andes, an increafe of heat, collected in its paffage over torrid regions; but before it arrives there, it muft have fwept along the fummits of the Andes, and comes impregnated with the cold of that frozen region. Befides, though the idea of a fouthern continent in that region of the globe which it was fuppofed to occupy is abandoned, it neverthelefs appears from Capt. Cook's difcoveries, that there is a large tract of land near the fouth pole, which is the fource of moft of the ice fpread over the vaft fouthern ocean. Whether, fays Dr. Robertfon, the influence of this remote frozen continent may reach the fouthern extremity of America, and affect its climate, is an inquiry not unworthy of attention. See ICE *iflands*.

Having confidered the variety of temperature to which different climates are fubject, we fhall next proceed to evince the change to which they have been fubject in different intervals of time, and to fpecify the moft obvious caufes of this change. This is a fubject to which various authors, both ancient and modern, have directed their attention; among thefe we may mention M. de Buffon, Hume, the Abbé du Bos, M. Pelloutier, the Hon. Daines Barrington, Dr. Williamfon of America, and Dr. Robertfon; but they have generally written on the fubject in a curfory manner. The moft complete differtation which we have feen, is that of the Abbé Mann, in the 6th volume of the "Tranfactions of the Electoral Academy of Sciences at Manheim." The firft part of this elaborate differtation is employed in demonftrating the fact, that a change of temperature and foil has actually taken place in the climates of Europe; and the fecond part contains an inquiry into the phyfical caufes of this change. The firft teftimony to the fact is that of Herodotus, who informs us, more than once, that in the European part of Scythia, in the Palus Mæotis, the winter continued eight months every year with almoft infupportable feverity; and that the countries farther northwards were on that account uninhabitable; and he adds, that the other four months, called fummer, were alfo exceedingly cold. In this country, which lies between the 44th and 50th degree of N. latitude, nothing of the like kind has taken place for a long time. Cæfar, Virgil, Diodorus Siculus, Ovid, Strabo, Pomponius Mela, Seneca, Petronius, Pliny the naturalift, Statius, Herodian, and Juftin, all fpeak to the fame purpofe of the infupportable cold of the winter in different parts lying in the fame latitude of from 44 to 50 degrees between Gaul and the Euxine fea. The defcriptions they concur in giving are fuch as would at prefent fuit thofe countries which lie between 56 degrees of latitude and the polar circle; and in fome refpects they feem to exceed the cold of the winter in Sweden and Norway. Indeed, their defcriptions of the climate of the middle part of Europe could at prefent be realized only in Lapland, Siberia, and thofe regions of America that lie to the north of Hudfon's bay, where the ftate of the climate is the fame with that which was found 2000 years ago on the banks of the Rhine and the Danube, the Palus Mæotis, the Dnieper, and the Don. The firft effect of the winter's cold in that whole part of Europe between the 44th and 50th degrees of latitude, uniformly mentioned by the ancients, is, that all the feas, lakes, and rivers contained in thofe diftricts were continually frozen, fo that armies of barbarians, Scythians and Sarmatians, paffed with their horfes, waggons, and baggage over the ice, in order to plunder the more fouthern countries. This is exprefsly afferted by Herodotus, Virgil, Ovid, and Strabo, of the European part of Scythia, Dacia, and Thrace, all of them countries which lay in a northern and weftern direction from the Palus Mæotis and the Euxine fea. The fame thing is afferted by Diodorus Siculus, Seneca, Pliny the younger, Florus, Herodian, Ammianus Marcellinus, Fernandez the Goth, and Xiphilinus the abridger of Dio Caffius, in regard to the rivers and lakes of Pannonia, Germany, and Gaul. In the treatife on rivers, afcribed to Plutarch, it is faid, that the Thermodon, a Scythian river, froze even in fummer; a circumftance which never happens at prefent with regard to the rivers of Siberia, Lapland, and Greenland. Ovid tells us, that he himfelf paffed over the Pontus Euxinus on the ice, and that oxen and carriages paffed over it. Plutarch fays, that the preffure of this enormous mafs of ice againft the fides of fhips frozen into it, crufhed them to pieces; and he mentions an inftance of a Roman fhip which had experienced the fame fate in the Danube. Strabo and Virgil fpeak of brafs veffels that burft by the expanfive force of the ice; and we are affured by Virgil and Ovid, that the people in Thrace and on the Danube cut the wine with axes, and diftributed it in folid portions.

> "Udaque confiftunt formam fervantia teftæ
> Vina, nec haufta meri, fed data frufta, bibunt."
> Ovid. lib. iii. el. 10.

They likewife add, that men's hair and beards were often covered with ice.

> "Cæduntque fecuribus humida vina.—
> Stiriaque impexis indurant horrida barbis."
> Virgil, Georg. l. iii.

> "Sæpe fonant moti glacie pendente capilli,
> Et nitet inducto candida barba gelu." Ovid.

If

If we compare this deſcription with the preſent ſtate of France, Germany, Hungary, Romania, Tranſylvania, Wallachia, Moldavia, Bulgaria, Leſſer Tartary, Podolia, and the Ukraine, it will be found that the preſent temperature of theſe countries has no reſemblance to what it was 2000 years ago. Moreover, Herodotus, Pomponius Mela, and Pliny the elder, ſpeak of the European part of Scythia as if its atmoſphere were continually filled with ſnow and fogs, which prevented the view of the neareſt objects, and obſcured the light of day. Diodorus Siculus ſpeaks of Celto-Scythia as covered with ſnow in the winter time; and this relation is confirmed by Florus and Petronius. Virgil, ſpeaking of Thrace and the countries on both ſides of the Danube, ſays, that a continual winter prevailed in them; and that the ſnow lay upon the ground ſometimes to the depth of 7 ells. Ovid ſays that at Tomi, lat. 44½°, placed by Dr. Wells, in his maps of Ancient Geography, in the 44th degree of N. latitude, the ſnow continued 2 years without being melted by the ſun or rain. Diodorus Siculus, Tacitus, and Ovid, when they ſpeak of Gaul, Germany, and Thrace, take notice of the prodigious force of the wind which prevailed in theſe countries in theſe times, and during the preceding centuries. Theſe winds raiſed even ſtones and men from the earth; carried away the roofs of houſes; tore up trees by the roots, and overturned turrets and houſes. Varro, Diodorus Siculus, Ovid, Pomponius Mela, Seneca, Petronius, Pliny the elder, Tacitus, Appian, Dio Caſſius, and Herodian, all agree in ſaying that the ſeverity of the climate and weather, which in their time prevailed in Gaul, Germany, Pannonia, Thrace, Moeſia, and Dacia, would hardly allow the culture of vines, olives, or any kind of fruit trees: and that, in cultivating them, it was neceſſary to cover them with dung, or with earth, to preſerve them throughout the winter. It is obſerved by Herodotus, Strabo, and Tacitus, that the oxen in the European part of Scythia and the country of the Celto-Scythians had no horns, or horns exceedingly ſmall; which they aſcribed to the ſeverity of the cold and climate. Strabo, as a proof of the great cold which prevailed in the country now called the Ukraine, obſerves, that it produced no aſſes;—animals, ſays he, that cannot endure the cold; and he adds, that the horſes there are extremely ſmall. Pauſanias expreſsly ſays, that in Thrace there were in his time bears and wild ſwine of a white colour. Such animals are found at preſent only in the remoteſt parts of the north, on the other ſide of the polar circle. Virgil, Ovid, and Pomponius Mela, inform us, that the inhabitants of the European part of Scythia and Thrace lived, during the whole winter, under the earth, as the Laplanders do at preſent; that they burnt large logs of wood to keep themſelves warm; that they never went abroad without being wrapped in ſkins; and that they left no part of the body uncovered but the mouth and eyes.

As a farther evidence of a change of climate, it has been alleged, that the rein-deer, from which the ſavage of the north derives the beſt comforts of his dreary life, is of a conſtitution that ſupports, and even requires the moſt intenſe cold. He is found in the rocks of Spitzberg, within 10 degrees of the pole; he ſeems to delight in the ſnows of Lapland and Siberia; but, at preſent, he cannot ſubſiſt, much leſs multiply, in any country to the ſouth of the Baltic; whereas in the time of Cæſar (vid. De Bell. Gallic. vi. 23, &c.) the rein-deer, as well as the elk and the wild bull, was a native of the Hercynian foreſt, which then overſhadowed a great part of Germany and Poland.

With a view of aſcertaining the boundaries of the northern countries, which the ancients deemed deſolate and uninhabitable on account of the great intenſity of the cold, we learn from Herodotus, that beyond the Melanchlini, a Sarmatian people, ſo called from their black hair, there were only lakes, moraſſes and unoccupied diſtricts as far as was then known; and we learn alſo from Ovid, that on the other ſide of the Cimmerian Boſphorus, the Tanais, and the Scythian moraſſes, a cold prevailed which rendered the country uninhabitable. Strabo repeatedly ſays, that all the lands towards the north of the tribes, who lived on the banks of the Tanais and the Boryſthenes, were uninhabitable on account of the ſeverity of the cold. This river, as far as it has been traced, does not lie beyond the 55th degree of latitude; and therefore it is on the ſame parallel with the northern parts of England and Germany, the middle of Lithuania, and the middle of Ruſſia. Strabo alſo ſays, that the whole northern part of Britain was very thinly peopled on account of the cold, and that he believed all the countries lying beyond it to be uninhabited. As no part of Great Britain extends beyond the 60th degree of north latitude, that parallel muſt include all Norway, almoſt the whole of Sweden, and the half of Ruſſia. Theſe countries, therefore, in the time of Strabo, that is, about the period of Auguſtus, were conſidered as uninhabited. The ancients, in general, ſpeak of all the lands which lay beyond the 55th degree of N. latitude as filled with lakes, moraſſes, ice, ſnow, and fogs, almoſt like thoſe countries to the north of Hudſon's Bay. From the authorities above cited, we derive ſufficient evidence of the exceſſive ſeverity which prevailed 2000 years ago in the climate of thoſe countries of Europe, lying between 44° and 50° N. lat. and of the difference between the ſtate of their temperature in that period and the preſent. The more northern lands, which the ancients, on account of their inſupportable cold, conſidered as uninhabitable; Iceland, Norway, Lapland, and the northern part of Ruſſia, and Siberia; are habitable, and actually inhabited, though exceſſively cold. The ancients alſo ſpeak of effects produced by the cold of winter in Italy, Greece, Leſſer Aſia, &c. which at preſent are certainly unknown. The ſoil of the latter countries, as well as that of the ancient Aſſyria, Chaldæa, Paleſtine, the Roman part of Africa, and Spain, is at preſent remarkably ſtony, and burnt up with heat. We know, however, that Spain in particular, about 1800 years ago, was exceedingly rich and fruitful, and abounded with all ſorts of proviſions, which are no longer to be found in it. The change of the ſoil and fertility in all the countries bordering on the Mediterranean Sea, and which formed the greateſt and moſt beautiful part of the Roman empire, is admitted as a certain fact, by all thoſe who have ſpoken of their former and preſent ſtate.

Upon the whole it may be affirmed as an unqueſtionable truth, that the ſoil and temperature of all the lands from Spain to India, and from the ridge of mount Atlas to Lapland and the remote parts of the north, have, in the courſe of ages, ſince the period of the oldeſt hiſtorical monuments ſtill extant to the preſent time, been gradually ſubjected to a complete change, from the utmoſt degree of moiſture and cold, to a great degree of dryneſs and warmth. The effect has been conſtant and uniform, and muſt therefore be traced to a correſponding cauſe. Dr. Williamſon (ubi ſupra) aſſerts, that the climate of America is becoming continually milder; and he confirms the aſſertion by a number of facts. This effect, indeed, is directly contrary to the hypotheſis of the celebrated naturaliſt, Buffon, reſpecting the theory of the earth and planets, who aſſerts, that they have been continually loſing warmth, ſince they were firſt in a ſtate of fuſion, and are becoming always colder; ſo that they will at length be incapable of keeping alive any animal or vegetable production. All hiſtorical and phyſical monuments, however, prove the contrary.

It is not merely in modern times, and ſince the improvement

ment of natural philosophy, that this change of temperature and soil has been noticed. A great number of places, well known and described by the ancients, in Palestine, Syria, Lesser Asia, Greece, Italy, Spain, and Barbary, exhibit proofs of the changes which have taken place in the soil and temperature in the course of time. Their present dry and barren state is well known, and seems to be irremediable. Columella is the first author who speaks of vines in Gaul; and he says that the Sabines and the Romans in the preceding century had procured, amidst the devastation of war, more abundant crops than had been procured in his time during a state of perfect peace. With regard to the changes of climate his observation is remarkable. "I find," says he, "that it is the opinion of many respectable authors, that the quality and state of the atmosphere became changed in the course of a long series of ages: for Saserna, in that work which he has left on agriculture, infers that the state of the atmosphere is changed, because certain districts, which formerly were incapable of producing vines and olives on account of the continued severity of the winter, now yield abundant vintages and plenty of oil, by the climate having become milder and warmer."

Many different causes have been alleged in order to account for those alterations of climate which we have above recited. Of these some are only accidental, and have taken place in different countries at very different periods; while in others some of them have not occurred at all. Among these the principal are the draining of lakes and morasses, the extirpation of forests, and the cultivation of land. All the ancient writers who speak of the countries of Europe beyond 50° N. lat. represent them as filled with lakes and morasses, and covered with immense forests, almost as America, in various parts of it, is at present. But of late years the people of America have been employed in extirpating the forests, draining the marshes, and cultivating the land; and it is well known that the climate there is become milder and more temperate. In the same manner the inhabitants of all the northern parts of Europe have for a thousand or two thousand years employed themselves in the improvement of the soil; and thus they have contributed to ameliorate the climate, not only in the countries that were thus cultivated, but even in neighbouring regions exposed to the effects of their atmosphere. In the southern parts of Europe there also existed a great number of lakes and morasses, which must have rendered the air exceedingly cold and moist, and consequently unhealthful; but in later periods few of these have remained, if we except such as may still be found in Sweden and Norway; though the places where they existed, both in England and on the continent, in Gaul, Germany, and the European Sarmatia, may still be distinctly perceived. It is well known, that in the time of Julius Cæsar, and even long after, almost the whole of Germany and Sarmatia was covered with immense forests. The Hercynian forest in particular was sixty days' journey in length, commencing in Belgic Gaul near the sea and extending through Germany and Poland. These forests which covered the mountains and plains, and the lakes or marshes which occurred in almost every valley, must have vitiated the air; and it is obvious that a very considerable change must have been produced by clearing the woods and draining off the stagnant waters. Large and thick woods prevent the solar beams from penetrating into the soil, and warming it; whilst their fallen leaves and branches rot on the ground and occasion a thick crust which impedes the escape and diffusion of the internal heat. They also concentrate the cold and moist vapours, render them putrid, and corrupt the whole atmosphere. This we find from the account of Dr. Williamson to have been particularly the case in the middle colonies of North America; and the consequences were bilious and intermittent fevers in summer and autumn, and inflammatory fevers in winter. But when these countries were cleared and cultivated, and the land was rendered more open and dry, the prevalence of such fatal diseases was restrained and diminished. The case must formerly have been the same in Europe under the like circumstances, and similar causes must have contributed to render its climate milder and more salubrious. The progress of cultivation and of agricultural improvements, was, however, in a great degree obstructed by the dispositions and habits of the Celts and Sarmatians, who were the first occupiers of all the European countries, which lay to the north of Italy and Greece. Like the other barbarous people that descended from them under different names, and over-ran the Roman empire in the 5th and 6th centuries, they despised agriculture, and cultivated only land sufficient to supply the wants of the current year. They subsisted chiefly by hunting and by feeding on the flesh of domestic animals which they reared in great numbers; and attention to these objects was regarded by them as much more dignified and important than the cultivation of land. This error has been sufficiently detected and exposed by the practice of more modern times; as it has been found that the culture of the earth, by breaking and softening its surface, has thus rendered it capable of imbibing the rays of the sun in summer, and of affording a passage to the internal heat in winter, and accordingly contributed to preserve a continual equilibrium between the heat of the earth and that of the atmosphere. The contrary takes place in all uncultivated countries, especially when they are moist and covered with wood. It cannot justly be questioned that the gradual draining of the stagnant water in Celto-Scythia and European Sarmatia, together with the destruction of their large forests and the general cultivation of the fields in these countries, must have had an influence, not only on the state of their own climate, but also on the atmosphere of Greece and Italy. Those cutting north-winds which converted every thing into ice, and of which the Greeks and the Romans complain so much, have in a great measure ceased, since the principal causes that produced them no longer exist. As long as Germany, Pannonia, Dacia, Moesia, and Thrace remained uncultivated and covered with immense forests, their atmosphere was extremely cold, thick, and heavy, and had a considerable influence on that of Italy and Greece, in which, because they were more open and warm countries, the atmosphere was consequently far lighter. The exertions of this fluid to recover its equilibrium were the causes of the cutting north-winds, of which the Greeks and the Romans complained so much. But when the whole of Celto-Scythia and Sarmatia became more open and better cultivated, their atmosphere must have come nearer to an equilibrium with that of Greece and Italy, and consequently those streams of air from the north must have decreased in the same proportion. This is a circumstance which must have contributed to moderate the climate of Greece and of Italy, and to render it much milder than it was about 1800 or 2000 years ago: and to such a degree that, if there had been no other cause, we could no longer wonder at, or entertain a doubt of, the effects of the cold which the ancients remarked in their time, and which are not observed at present. The honourable Daines Barrington (See Phil. Trans. vol. 58.) having shewn by the authorities which we have already cited, contrasted against those of modern travellers, that the climate of Tomus or Tomi, supposed to be the same with the present Temesware, whither Ovid was banished, has undergone a very considerable change, urges this fact against the

the common obfervation, that the cultivation of a country will render the climate more temperate: "becaufe," he fays, "the adjacent country is now in the fame ftate that it was in the time of Ovid." He adds, "that Italy was better cultivated in the Auguftan age than it is now, which fhould confequently have made the temperature of the air more warm than it is now experienced to be. Virgil, in his "Georgics," is conftantly advifing precautions againft fnow and ice in the management of cattle; and fpeaking of Calabria, the moft fouthern part of Italy, he expreffes himfelf with regard to the rivers being frozen, as what was commonly to be expected. It appears alfo from the 6th fatire of Juvenal, that the Tyber's being commonly frozen in winter, fupplied the ladies of Rome with a very extraordinary inftance of implicit deference to the commands of the Egyptian priefts in the performance of their ablutions.

"Hybernum fracta glacie defcendet in amnem,
Ter matutino Tyberi mergetur ——"

In farther proof of the fact, that the Italian rivers were conftantly frozen over, a paffage is cited from Ælian (De Animal. lib. xiv. cap. 29.), which confifts of inftructions how to catch eels, whilft the water is covered with ice; whereas, if we may believe the concurrent accounts of modern travellers, it would be almoft as ridiculous to advife a method of catching fifh in the rivers of Italy, which depended entirely upon their being commonly frozen over, as it would be to give fuch directions to an inhabitant of Jamaica. Many paffages of Horace fuppofe the ftreets of Rome full of fnow and ice. The winters are now unqueftionably much more temperate at Rome than formerly. At prefent the Tyber no more freezes at Rome, than the Nile at Cairo. Indeed, the Romans term the winter very rigorous, if the fnow lie two days; and, if one fee for 48 hours a few icicles hang from a fountain that has a north expofure. To the facts above-mentioned, it may be fufficient to refer to what has been already obferved with regard to the influence of the winds; or to allege, that the cultivation of a country, though one, is not the only caufe of the amelioration of its climate. If it fhould be faid, that as the cold of winter decreafes, by the operation of the caufes now recited, the heat of fummer ought to increafe in the fame proportion; the abbé Mann admits the fact, and thinks it demonftrable by many monuments, hiftorical as well as phyfical, that the fum-total of the mean fummer heat is greater than it was formerly, and that it continually increafes, though at long intervals, and in an imperceptible manner. With refpect to that ftifling heat which is occafionally experienced even in Lapland, he thinks that it is leffened by all the caufes which diminifh the cold of winter. Experience teaches us, that the thinner, purer, and more elaftic the air is, the lefs, in the fame proportion, is the intenfity of the fummer heat; and, on the contrary, the thicker the atmofphere is, and the more it is filled with ftagnant and concentrated vapours, the heat is more intenfe and more ftifling. For this reafon it is always cooler on the fummits of high mountains, while a ftifling and infupportable heat prevails in the neighbouring plains, efpecially when they are furrounded with wood. This is always obferved in the favannahs of America. Dr. Williamfon concurs in this opinion, and obferves, that when the extenfive country of North America becomes entirely open, when its woods are cut down, and its plains cultivated, the feverity of the winter cold will not only decreafe, but the ftifling unhealthful heat of the fummer will be moderated. The quantity of fnow, ice, and moifture, is already evidently leffened; and many plants, which could not be cultivated there formerly, now thrive and fucceed. The abbé Mann alleges another, and, in his eftimation, principal caufe of the amelioration of climate, the agency of which is general and uniform, that is, an union of the two diftinct principles, moifture and heat. The principle of heat, he fays, increafed continually in the courfe of time, fo as to overcome the oppofite principles of moifture and cold, renders, by thefe means, the earth drier and fuller of ftones, and confequently increafes the fum of the degree of heat. Without this principle, it is his opinion, that we can never find fufficient grounds for the wonderful changes which have taken place in the nature of the foil of all thofe lands which border on the Mediterranean fea, which formed the ancient empire of Rome, from Syria to India, and which at prefent are all become uncommonly fruitful, dry, and ftony. The mere neglect of agriculture could never have produced thefe effects, and muft have been attended rather with effects of a contrary nature.

That the difference of climate has a very confiderable influence on the productions of the foil, and on the animals of every fpecies, that occupy particular diftricts of the globe, is a fact that has been very generally acknowledged. But the extent and degree of this influence are fubjects, with regard to which different writers have expreffed very different fentiments. Dr. Robertfon adopts the general ideas of count de Buffon, and M. de Paw, on this fubject; and in its relation to America, obferves, that the uncultivated ftate of the New World affected not only the temperature of the air, but the qualities of its productions. The principle of life, he fays, feems to have been lefs active and vigorous there than in the ancient continent. So that, notwithftanding the vaft extent of America and the variety of its climates, the different fpecies of animals peculiar to it are much fewer in proportion than thofe of the other hemifphere. Of 200 different kinds of animals, according to Buffon, fpread over the face of the earth, only about one-third exifted in America at the time of its difcovery. Befides, nature, it is faid, was not only lefs prolific in the new world, but fhe appears to have been likewife lefs vigorous in her productions. The animals originally belonging to this quarter of the globe appear to be of an inferior race, neither fo robuft nor fo fierce, as thofe of the other continent. The fame qualities in the climate of America, which ftinted the growth, and enfeebled the fpirit of its native animals, have proved pernicious to fuch as have migrated into it voluntarily from the other continent, or have been tranfported thither by the Europeans. Moft of the domeftic animals with which the Europeans ftored the provinces in which they fettled, have degenerated with refpect either to bulk or quality, in a country whofe temperature and foil feem to be lefs favourable to the ftrength and perfection of the animal creation. It is further alleged, that the fame caufes which checked the growth and the vigour of the more noble animals, have favoured the propagation and increafe of reptiles and infects, which multiply fafter, perhaps, in America than in other parts, and grow of a more monftrous bulk. The birds, alfo, of the new world, are not diftinguifhed by qualities fo confpicuous and characteriftical, as thofe which have been obferved in its quadrupeds; fo that fuch as are peculiar to America nearly refemble thofe with which mankind were acquainted in fimilar regions of the ancient hemifphere. The American birds of the torrid zone, like thofe of the fame climate in Afia and Africa, are decked in plumage, which dazzles the eye with the vivid beauty of its colours; neverthelefs, nature, fatisfied with clothing them in this gay drefs, has denied moft of them that melody of found, and variety of notes, which catch and delight the ear. In fome diftricts of America, the unwholefome temperature of the air feems to be unfavourable even to this part of the creation. The number of birds is lefs than in other countries, and

and the traveller is ſtruck with the amazing ſolitude and ſilence of its foreſts. Moreover, although the ſoil, in a continent ſo extenſive as America, muſt of courſe be extremely various; yet it may be obſerved in general, that moiſture and cold, which predominate ſo remarkably in all parts of America, muſt have great influence on its nature and productions; and, therefore, chilled by intenſe cold, the ground never acquires warmth ſufficient to ripen the fruits, which are found in the correſponding parts of the other continent. Allowing, however, for the diverſity that occurs in a continent ſo extenſive, the ſoil of America is naturally as rich and fertile as in any part of the earth.

In order to account for the condition and character of the Americans, ſome philoſophers (as count de Buffon) have maintained, that that part of the globe, occupied by them, had but lately emerged from the ſea, and become fit for the reſidence of man; that every thing in it bore marks of a recent original; and that its inhabitants lately called into exiſtence, and ſtill at the beginning of their career, were unworthy to be compared with the people of a more ancient and improved continent. Others (*e. g.* M. de Paw) have imagined, that, under the influence of an unkindly climate, which checks and enervates the principle of life, man never attained in America the perfection which belongs to his nature, but remained an animal of an inferior order, defective in the vigour of his bodily frame, and deſtitute of ſenſibility, as well as of force, in the operations of his mind. In oppoſition to both theſe, other philoſophers (as M. Rouſſeau) have ſuppoſed, that man arrives at his higheſt dignity and excellence long before he reaches a ſtate of refinement; and, in the rude ſimplicity of ſavage life, diſplays an elevation of ſentiment, and independence of mind, and a warmth of attachment, for which it is vain to ſearch among the members of poliſhed ſocieties. Accordingly the rude manners of the Americans have been propoſed as models to the reſt of the ſpecies. Dr. Robertſon, in his judicious and elaborate inveſtigation of this intereſting ſubject, cautions thoſe who inquire concerning either the bodily or mental qualities of particular races of men, from being miſled by the common or ſeducing error of aſcribing to a ſingle cauſe thoſe characteriſtic peculiarities, which are the effect of the combined operations of many cauſes. Some philoſophers of great eminence, he ſays, finding that the climate and ſoil of America differ, in ſo many reſpects, from thoſe of the other hemiſphere, have laid hold on this as ſufficient to account for what is peculiar in the conſtitution of its inhabitants. Accordingly they reſt on phyſical cauſes alone, and conſider the feeble frame and languid deſire of the Americans as conſequences of the temperament of that portion of the globe which they occupy. But he thinks that the influences of political and moral cauſes ought not to have been overlooked. Theſe operate with no leſs effect than that on which many philoſophers reſt as a full explanation of the ſingular appearances that are diſcernible in the bodily conſtitutions and mental qualities of the inhabitants of the New World. However, in contemplating the inhabitants of a country ſo widely extended as America, great attention ſhould be paid to the diverſity of climates under which they are placed. The American provinces are of ſuch different temperament, that this alone is ſufficient to conſtitute a diſtinction between their inhabitants. In every part of the earth where man exiſts, the power of climate operates, with deciſive influence, upon his condition and character; and in thoſe countries which approach near to the extremes of heat or cold, this influence is ſo conſpicuous as to ſtrike every beholder. Whether we conſider man, ſays Dr. Robertſon, merely as an animal, or as a being endowed with rational powers, which fit him for activity and ſpeculation, we ſhall find that he has uniformly attained the greateſt perfection of which his nature is capable, in the temperate regions of the globe. There his conſtitution is moſt vigorous, his organs moſt acute, and his form moſt beautiful. There, too, he poſſeſſes a ſuperior extent of capacity, greater fertility of imagination, more enterpriſing courage, and a ſenſibility of heart which gives birth to paſſions, not only ardent, but perſevering. In this favourite ſituation he has diſplayed the utmoſt efforts of his genius, in literature, in policy, in commerce, in war, and in all the arts which improve or embelliſh life. (See Ferguſon's Eſſay on the Hiſtory of Civil Society, part iii. c. i.) This powerful operation of climate is felt moſt ſenſibly by rude nations, and produces greater effects than in ſocieties more poliſhed. The talents of civilized men are continually exerted in rendering their conſtitution more comfortable; and by their ingenuity and inventions, they can, in a great meaſure, ſupply the defects, and guard againſt the inconveniences, of any climate. But the improvident ſavage is affected by every circumſtance peculiar to his ſituation. He takes no precaution either to mitigate or to improve it. Like a plant or an animal, he is formed by the climate under which he is placed, and feels the full force of its influence. This natural diſtinction between the inhabitants of the temperate and torrid zones is ſignally exemplified among the rude nations of America. Thoſe of the former claſs comprehend the North Americans from the river St. Lawrence to the gulf of Mexico, together with the people of Chili, and a few ſmall tribes towards the extremity of the ſouthern continent. In this claſs, the human ſpecies appears manifeſtly to be more perfect; the natives are more robuſt, more active, more intelligent, and more courageous; and they poſſeſs, in the moſt eminent degree, that force of mind, and love of independence, which are the chief virtues of man in a ſavage ſtate. To the other claſs belong all the inhabitants of the iſlands, and thoſe ſettled in the various provinces which extend from the iſthmus of Darien almoſt to the ſouthern confines of Braſil, along the eaſt ſide of the Andes; and over theſe the Europeans have moſt completely eſtabliſhed their dominion, whilſt the others have defended their liberty againſt them with perſevering fortitude. It is allowed, however, that moral and political cauſes affect the diſpoſition and character of individuals, as well as nations, ſtill more powerfully than the influence of climate. Accordingly, ſome tribes have been found in various parts of the torrid zone, who poſſeſs courage, high ſpirit, and the love of independence, in a degree hardly inferior to the natives of more temperate climates. Upon the whole, it is not by attending to any ſingle cauſe or principle, however powerful and extenſive its influence may appear, that we can explain the actions, or account for the character of men. Even the law of climate, more univerſal, perhaps, in its operation than any that affects the human ſpecies, cannot be applied in judging of their conduct, without many exceptions. (Robertſon's Hiſt. Amer. book iv.)

Clavigero, in his "Hiſtory of Mexico," has defended the climate and ſoil of America againſt the objections of count de Buffon and M. de Paw. He begins with ſhewing that the lakes and marſhes, which theſe writers have conſidered as traces of a general inundation, are merely the effects of the great rivers, innumerable fountains, and very plentiful rains of America. Whoever has obſerved, he ſays, the ſtupendous elevation of the inland countries of America, will not eaſily perſuade himſelf that the water could riſe ſo as to cover them without inundating Europe. To the proof alleged by M. de Paw of the overflow of the ſoil by water, from

from the veins of metals which are found near the ſurface of the earth, he replies that this phenomenon may much more [illegible] be accou[illegible]er by ſuppoſing that ſome violent eruptions of ſubterraneous fires, which appear manifeſt in the many volcanoes of the Cordilleras, deſtroyed the ſurface of ſome ſoils, and left the veins of metals almoſt naked. The diſcovery of marine bodies, heaped up together in ſome inland places of America, if it ſhould prove the pretended inundation, would prove ſtill more ſtrongly a greater inundation of the old continent, in which they are much more abundant. As to the extinction or deſtruction of the great quadrupeds of America, which M. de Paw ſays are the firſt to periſh in water, and which, as he ſuppoſes, periſhed in this imaginary inundation, Clavigero thinks it aſtoniſhing that elephants and camels, which are ſo ſwift in their motion, ſhould periſh, and that the ſloth, which is ſo ſlow, and unable to move, ſhould have eſcaped. Although we ſhould admit that ſuch quadrupeds have formerly exiſted in America, we are not obliged to believe that their deſtruction has been occaſioned by the ſuppoſed inundation, becauſe it might be aſcribed to other very different cauſes. After examining and refuting ſome other arguments of M. de Buffon, Clavigero denies the reality of the inundation, which theſe writers ſuppoſe; more eſpecially as there has been no record or tradition among the Americans of any other inundation than that univerſal deluge which is mentioned in ſcripture.

Againſt the charges of Meſſrs. Buffon and de Paw, who repreſent the ſoil of America as barren, and its whole territory as compoſed of inacceſſible mountains, impenetrable woods and waſtes, watry plains and marſhes, the Mexican hiſtorian alleges the teſtimony of Acoſta, who obſerves, that if there be any land in the world to which the name of Paradiſe may be applied, it is that of America, and he adduces the multitude, variety, and excellence of its vegetable productions, and particularly thoſe of Mexico and Peru, as an evidence of the fertility of its lands.

Clavigero, after a variety of obſervations on the ample ſupply of vegetables furniſhed by the different climates of America, proceeds to examine one of the principal arguments urged by Buffon and de Paw in proof of the poverty of the ſoil and malignity of the climate of America, which is the degeneracy of animals, both ſuch as are natives and ſuch as are tranſported thither from the ancient continent. The firſt ground of diſparagement to America, in the judgment of count de Buffon, is the ſmall number of its quadrupeds, compared with thoſe of the old continent. He reckons (as we have already obſerved) 200 ſpecies of quadrupeds hitherto diſcovered over the whole globe, of which 130 belong to the old continent, and only 70 to the new world. To this argument it is replied, that the extent of America is one-third part of the whole earth, and that it appears to have one-third part, or its due proportion, of all the ſpecies of quadrupeds. But it is difficult to aſcertain the true number of ſpecies, and to aſſign to each its proper proportion; and therefore all reaſoning on this topic muſt be in a degree vague and inconcluſive. In the enumeration and arrangement of the natural hiſtorian himſelf, there is a conſiderable degree of confuſion and ſelfcontradiction. But it is alleged, that all the animals of America are of a much ſmaller ſize than they are in Europe; but no argument can be fairly deduced from this circumſtance againſt the ſoil or climate of America; becauſe according to principles eſtabliſhed by Buffon himſelf, the larger kinds of animals are peculiar to intemperate climes, and the ſmaller to climes which are mild and temperate: and if the advantages of climate are to be deduced from the ſize of quadrupeds, one might juſtly ſay, that the climate of Africa and the ſouth of Aſia is much better than that of Europe. But the fact, in its unlimited extent, is not true, and has been contradicted even by Buffon himſelf. It has been alſo ſaid that the animals of South America, which are thoſe that properly belong to the new continent, are almoſt all deprived of tuſks, horns, and tails; that they are deformed in figure, their limbs being diſproportionate, and ill ſet; and that ſome of them, as the ant-killers and ſloths, are of ſo miſerable a nature, that they have hardly ability to move and eat. However, it would be difficult to prove that any irregularity in the conformation of different animals is owing to the climate of America, or that it is peculiar to that country. What our philoſophers have ſaid with reſpect to the leſs ferocity of American wild beaſts; inſtead of aſſiſting them to prove the malignity of that climate, ſerves only, on the principle expreſsly ſtated by Buffon himſelf, to demonſtrate its mildneſs and bounty. A decreaſe of ferocity, therefore, cannot be juſtly pleaded as a proof of degeneracy occaſioned by the malignity of the climate. But if the American quadrupeds are ſmaller in ſize, more ungraceful in form, and more puſillanimous in their nature than thoſe of the old continent, this circumſtance would not afford a certain argument of the malignity of the American climate, becauſe the ſame degeneracy is not manifeſt in the reptiles and birds of America. It has been ſaid, with regard to American birds, that, though they are ſuperior in beauty of plumage, they are exceeded in excellence of ſong by thoſe of Europe. This fact, however, has been contradicted; and it has been aſſerted that the ſong of the nightingale is more melodious, more varied, and more durable in America than in Europe. The centzontli or polyglot is preferred even to the nightingale, with reſpect to the ſingular ſweetneſs of its ſong, the prodigious variety of its notes, and the talent it poſſeſſes of counterfeiting the different tones of the birds and quadrupeds which it hears. As a further proof of the degeneracy of quadrupeds in America, it has been ſaid that all the animals tranſported from Europe to America, ſuch as horſes, aſſes, bulls, ſheep, goats, hogs, and dogs, are conſiderably ſmaller there than they are in Europe, and, as Buffon ſays, without one ſingle exception. If we ſeek for the proof of this univerſal aſſertion, we ſhall find no other, ſays Clavigero, in the whole hiſtory of that philoſopher than that cows, ſheep, goats, hogs, and dogs, are ſmaller in Canada than they are in France. The Mexican hiſtorian proceeds to examine and refute the charge of degeneracy in the human ſpecies occaſioned by the malignity of the climate. Accordingly he maintains, that the Americans, in general, are neither more diminutive in ſtature, nor more deformed and feeble, nor more ſubject to diſeaſe than the Europeans; and where any inſtances occur to the contrary, he attributes them to incidental cauſes and not to the influence of the climate. After an inveſtigation of the corporeal qualities of the Americans, he produces a variety of atteſtations and arguments in favour of their mental powers and attainments. Although ſome miſſionaries, aſtoniſhed equally at their ſlowneſs of comprehenſion, and at their inſenſibility, have pronounced them to be a race of men ſo brutiſh, as to be incapable of underſtanding the firſt principles of religion, Clavigero contends, that their teſtimony cannot be truſted. He corrects ſome miſtakes of Dr. Robertſon on this ſubject, and particularly his miſapprehenſion of a decree iſſued by a council at Lima in 1552, which excluded the Indians from the euchariſt on account of their incapacity, and alſo of a bull of Paul III. iſſued in 1537, which is ſaid to have declared them to be rational creatures, intitled to all the privileges of chriſtians; whereas, he ſays, it was merely intended to certify their right to all the privileges of men, and thus to condemn their oppreſſors. "We have had intimate commerce with the Americans," ſays the hiſtorian of Mexico, "have lived for

ſome

fome years in a feminary deftined for their inftruction, faw the erection and progrefs of the royal college of Guadaloupe, founded in Mexico, by a Mexican Jefuit, for the education of Indian children, had afterwards fome Indians among our pupils, had particular knowledge of many American rectors, many nobles, and numerous artifts; attentively obferved their character, their genius, their difpofition, and manner of thinking; and have examined befides with the utmoft diligence their hiftory, their religion, their government, their laws, and their cuftoms: and after fuch long experience and ftudy of them, from which we imagine ourfelves enabled to decide without danger of erring, we declare to M. de Paw, and to all Europe, that the mental qualities of the Americans are not the leaft inferior to thofe of the Europeans, that they are capable of all, even the moft abftract fciences, and that if equal care was taken of their education, if they were brought up from childhood under good mafters, were protected and ftimulated by rewards, we fhould fee rife among the Americans, philofophers, mathematicians, and divines who would rival the firft in Europe. But it is a little difficult, not to fay impoffible, to make great progrefs in the fciences in the midft of a life of mifery, fervitude, and oppreffion." He adds, "the whole ancient hiftory of the Mexicans and Peruvians evinces to us, that they knew how to think and order their ideas, that they are fufceptible of all the paffions and impreffions of humanity, and that the Europeans have had no other advantage over them than that of having been better inftructed. The civil government of the ancient Americans, their laws, and their arts, evidently demonftrate they fuffered no want of genius. Their wars fhew us that their fouls are not infenfible to the excitements of love, as count de Buffon and M. de Paw think;" and of their courage there can be no queftion. For other particulars with regard to their general character, cuftoms, literature, &c. &c. we muft refer to the "Differtations" annexed to Clavigero's Hiftory of Mexico.

Montefquieu in his "Spirit of Laws," (Book xiv. xvii.) examines the influence of different climates on the bodily conftitution of individuals, and on the manners, characters, government, laws, and religion of different nations. The character of the mind, fays this writer, and the paffions of the heart are extremely different in different climates; and the laws ought to be relative both to the difference of thefe paffions, and to the difference of thofe characters.

In cold countries people are more vigorous; and fuperiority of ftrength produces a great many effects; *v. g.* a greater boldnefs, that is, more courage; a greater fenfe of fuperiority, that is, lefs defire of revenge; a greater opinion of fecurity, that is, more franknefs, lefs fufpicion, policy and cunning. On the other hand, the inhabitants of warm countries are more feeble and timorous, and poffefs a more exquifite fenfibility; fo that as climates are diftinguifhed by degrees of latitude, they might alfo be diftinguifhed in fome meafure, by degrees of fenfibility. The heat of the climate, he fays, may be fo exceffive as to deprive the body of all vigour and ftrength. Then the faintnefs is communicated to the mind; there is no curiofity, no noble enterprize, no generous fentiment; the inclinations are all paffive; indolence conftitutes the utmoft happinefs; no punifhment hardly is fo fevere as the action of the foul; and flavery is more fupportable than the force and vigour of mind neceffary for human conduct. Hence the Indians are naturally a cowardly people; and even the children of the Europeans, born in the Indies, lofe the courage peculiar to their own climate. This celebrated writer, reflecting on what the Greeks and Romans have faid of Afiatic effeminacy, and the accounts given by travellers of the indolence of the Indians, is of opinion, that this indolence forms the diftinguifhing character of thofe countries. Purfuing his inquiries into the common caufe of this general fact, and finding, that all thefe nations inhabit what are called "hot countries," he has attributed the caufe of their indolence to heat; and affuming the fact as a principle, has laid it down as an axiom, that the inhabitants of hot countries muft neceffarily be indolent, inert of body, and from analogy, likewife inert of mind and character. He proceeds even ftill farther, remarking, that unlimited monarchy is the moft ufual form of government among thefe nations; and confidering defpotifm as the effect of the fupinenefs of a people, he concludes that defpotifm is as much the natural government of thefe countries and as neceffary as the climate under which they live. This fyftem has been received with great applaufe in France, nay, even throughout Europe, and the opinion of Montefquieu is become, among the moft numerous clafs of reafoners, an authority from which it is prefumptuous to differ. A late writer (Volney) has contefted this opinion, and fuggefted feveral objections againft it. "The doctrine," he fays, (Travels in Egypt and Syria, vol. ii.) "of the general indolence of the oriental and fouthern nations, is founded on that opinion of Afiatic effeminacy originally tranfmitted to us by the Greeks and Romans; but what are the facts on which that was built?"—"Admitting the facts as we receive them from hiftory, were the Affyrians, whofe ambition and wars during 500 years threw Afia into confufion; the Medes, who fhook off their yoke, and difpoffeffed them; the Perfians, who, under Cyrus, within the fpace of 30 years, extended their conquefts from the Indus to the Mediterranean; were thefe inert and indolent people? May we not oppofe to this fyftem the Phœnicians, who, for fo many centuries, were in poffeffion of the commerce of the whole ancient world: the Palmyrenians, of whofe induftry we poffefs fuch ftupendous monuments; the Carduchi of Xenophon, who braved the power of the "great king," in the very heart of his empire: the Parthians, thofe unconquerable rivals of Rome; and even the Jews, who, limited to a little ftate, never ceafed to ftruggle, for a thoufand years, againft the moft powerful empires? If the men of thefe nations were inert, what is activity? If they were active, where then is the influence of climate? Why in the fame countries where fo much energy was difplayed in former times, do we at prefent find fuch profound indolence? Why are the modern Greeks fo debafed amidft the very ruins of Sparta and Athens, and in the fields of Marathon and Thermopylæ? Will it be alleged, that the climate has changed? Where are the proofs? Suppofing this true, it muft have changed by irregular fits; the climate of Perfia muft have altered greatly from Cyrus to Xerxes; that of Athens from Ariftides to Demetrius Phalereus; and that of Rome from Scipio to Sylla, and from Sylla to Tiberius. The climate of the Portuguefe muft have changed fince the days of Albuquerque; and that of the Turks fince Solyman? If indolence be peculiar to the fouthern countries, how are we to account for a Carthage in Africa, Rome in Italy, and the Buccaneers at St. Domingo? Why do we meet with the Malays in India, and the Bedouins in Arabia? Why, too, at the fame period, and under the fame fky, do we find a Sybaris near Crotona, a Capua in the vicinity of Rome, and a Sardis contiguous to Miletus? Whence is it, that we fee, under our own eyes, and in Europe itfelf, northern governments as languid as thofe of the fouth? Why, in our own country, are the fouthern more active than the northern provinces? If the fame effects are obfervable under directly contrary circumftances, and different effects under the fame circumftances, what becomes of thefe pretended principles? What is this induinfluence of climate? and what is to be underſtood by activity? Is it only to be accorded to warlike nations? and was Sparta when not engaged in war to be eſteemed inert? What do we mean by hot countries? Where are we to draw the line of cold and temperate? Let the partizans of Monteſquieu aſcertain this, that we may henceforward be enabled to determine the quantity of energy in a nation by the temperature, and at what degree of the thermometer we are to fix its aptitude to ſlavery or freedom. But a phyſical obſervation has been called in to corroborate this poſition; and we are told that heat abates our ſtrength; we are more indolent in ſummer than in winter: the inhabitants of hot countries, therefore, muſt be indolent. Let us ſuppoſe this true. Whence is it then, that, under the ſame influence of climate, the tyrant poſſeſſes more energy to oppreſs than the people to defend themſelves? But, is it not evident that we reaſon like the inhabitants of a country where cold is more prevalent than heat? Were a ſimilar theſis to be maintained in Egypt and Africa, it would there be ſaid, that cold prevents motion, and obſtructs the circulation? The truth is, that our ſenſations are relative to our habits, and that bodies aſſume a temperament analogous to the climate in which they live; ſo that they are only affected by the extremes of the ordinary medium. We hate ſweating; the Egyptian loves it, and dreads nothing ſo much as a failure of perſpiration. Thus, whether we refer to hiſtorical or natural facts, the ſyſtem of Monteſquieu, ſo ſpecious at firſt ſight, turns out, when examined, to be a mere paradox, which has owed its ſucceſs only to the impreſſion made by the novelty of the ſubject, at the time the "Spirit of Laws" appeared, and the indirect flattery it offered to thoſe nations by which it was ſo favourably received."

The author then proceeds to inveſtigate the origin and motives of activity in man; and concludes, that all action, whether of body or mind, has its ſource in our neceſſities, and augments as they increaſe. Accordingly we may follow its gradations from the rudeſt beginnings in the moſt ſavage ſtate of man, when hunger and thirſt awaken the firſt exertions of the ſoul and body, to the ſtate of the moſt mature improvement. In ſuch a progreſs, as in the primary cauſe, it muſt be acknowledged, that activity has little or no connection with heat; only the inhabitants of the north being reputed to ſtand more in need of nouriſhment than thoſe of the ſouth, it may be alleged, that they muſt conſequently be poſſeſſed of more activity; but this difference in neceſſary wants has very narrow limits. The facility of obtaining a great quantity of food, which is perhaps the primary cauſe of voraciouſneſs, depends leſs, eſpecially in a ſavage ſtate, on climate than on the nature of the ſoil, and its richneſs or poverty in paſturage, in foreſts, and in lakes; and conſequently in game, fiſh, and fruits; circumſtances which are found indifferently under every parallel. Hence it appears, that the nature of the ſoil has a real influence on activity; and we muſt perceive, that, in the ſocial as in the ſavage ſtate, a country, in which the means of ſubſiſtence are ſomewhat difficult to be procured, will have more active and more induſtrious inhabitants; while in another, where nature has laviſhed every thing, the people will be indolent and inactive. This is perfectly conformable to hiſtorical fact; for we always find the conquering nations poor, and iſſuing from lands either barren, or difficult of cultivation; while the conquered people are inhabitants of fertile and opulent countries. Theſe needy conquerors, eſtabliſhed among rich nations, ſhortly loſe their energy, and become effeminate. Such was the caſe with the Perſians, who, under Cyrus, deſcended from the Elymais into the fertile fields watered by the Euphrates; ſuch were the Macedonians under Alexander, when tranſplanted from mount Rhodope to the plains of Aſia; ſuch the Tartars of Gengis-khan, when ſettled in China and Bengal; and ſuch the Arabs ſo victorious under Mahomet, after the conqueſt of Spain and Egypt. It is not, therefore, as inhabitants of hot, but as inhabitants of rich countries, that nations are inclined to indolence; and this maxim is exactly conformable with what we obſerve in ſociety in general, ſince we ſee there is always leaſt activity among the more opulent claſſes; but as this ſatiety and poverty do not exiſt for all the individuals of a nation, we muſt recur to reaſons more general and more efficacious, than the nature of the ſoil. "I mean," ſays M. Volney, "the ſocial inſtitutions, called *Government* and *Religion*." Theſe are the true ſources and regulators of the activity or indolence of individuals and nations. Theſe are the efficient cauſes, which, as they extend or limit the natural or ſuperfluous wants, limit or extend the activity of all men. A proof that their influence operates in ſpite of the difference of climate and ſoil is, that Tyre, Carthage, and Alexandria, formerly poſſeſſed the ſame induſtry as London, Paris, and Amſterdam; that the Buccaneers and the Malayans, have diſplayed equal turbulence and courage with the Normans; and that the Ruſſians and Polanders have the apathy and indifference of the Hindoos and the Negroes. But as civil and religious inſtitutions are perpetually varied and changed by the paſſions of men, their influence changes and varies in very ſhort intervals of time. Hence it is that the Romans, commanded by Scipio, reſembled ſo little thoſe governed by Tiberius; and that the Greeks of the age of Ariſtides and Themiſtocles were ſo unlike thoſe of the time of Conſtantine. Let us examine what paſſes within ourſelves. Do we not experience, that our activity has leſs dependence on phyſical cauſes, than the actual circumſtances of the ſociety of which we are members? Are our deſires excited by neceſſary or ſuperfluous wants; both our bodies and minds are animated with new life; paſſion inſpires us with an activity ardent as our deſires and perſevering as our hopes. Are theſe hopes diſappointed; deſire decays, activity languiſhes, and diſcouragement induces apathy and indolence. This explains why our activity varies with our conditions, our ſituations, and the different periods of our life. Why does the man, who was active in his youth, become indolent in his old age? why is there more activity in capital and commercial cities, than in towns without commerce and in the country? To awaken activity, there muſt be objects of deſire, and to maintain it, the hope of arriving at enjoyment. If theſe two eſſentials are wanting, there is an end to individual and national activity. Such is the condition of the Orientals in general.—What ſhould induce them to move, if no motion procures them the hope of an enjoyment equivalent to the trouble they muſt take? How can they be otherwiſe than indolent in their moſt ſimple habits, if their ſocial inſtitutions render it a ſort of neceſſity? The moſt intelligent obſerver of antiquity, after having made the ſame remark on the Aſiatics of his time, has aſſigned the ſame reaſon.

"As to the effeminacy and indolence of the Aſiatics (ſays Hippocrates, De Aëre, Locis, et Aquis), if they are leſs warlike and more gentle in their manners than the Europeans, no doubt the nature of their climate, more temperate than ours, contributes greatly to this difference. But we muſt not forget the form of their governments, which are all deſpotic, and ſubject to the arbitrary will of their kings. Men who are not permitted the enjoyment of their natural rights, but whoſe paſſions are perpetually under the guidance of their maſters, will never be found courageous in battle. To

them

them the riſks and advantages of war are by no means equal. Obliged to forſake their friends, their country, their families; to ſupport cruel fatigues, and even death itſelf, what is the recompence of ſo many ſacrifices? Danger and death. Their maſters alone enjoy the booty and the ſpoils they have purchaſed with their blood. But let them combat in their own cauſe, and reap the reward of their victory, or feel the ſhame of their defeat, they will no longer be deficient in courage; and the truth of this is ſufficiently proved by both the Greeks and Barbarians, who, in thoſe countries, live under their own laws, and are free; for they are more courageous than any other race of men." Upon the whole, M. Volney obſerves, as a fact which cannot be diſputed, that "the moral character of nations, taken from that of individuals, chiefly depends on the ſocial ſtate in which they live; ſince it is true, that our actions are governed by our civil and religious laws; and ſince our habits are no more than a repetition of thoſe actions, and our character only the diſpoſition to act in ſuch a manner, under ſuch circumſtances, it evidently follows, that theſe muſt eſſentially depend on the nature of the government and religion."

CLIMATE *for plants*. See TEMPERATURE.

CLIMATE, in *Agriculture*, a certain tract or ſpace on the ſurface of the earth, varying in the ſtate or temperature of the air. It has been ſtated by Mr. Donaldſon, that "it is the firſt natural advantage of every country; that which is abſolutely requiſite for animal, as well as vegetable life; that without which, ſoil and cultivation will avail little; for although ſoil may be improved with complete ſucceſs, climate cannot to any very conſiderable extent. It is well known that, beſides the particular ſituation of a country on the globe, other circumſtances combine in forming its climate; ſuch as its elevation, proximity to oceans, ſeas, mountains, marſhes, ſoil, and the like; upon ſuch natural cauſes, the climate of this country, he ſays, depends; and from theſe receives its character. (See the preceding article.) There are three diſtinct characteriſtics of our climate, that cannot eſcape the obſervation of thoſe who have made it an object of attention, and from which its advantages or diſadvantages muſt appear: 1ſt, its mildneſs; 2d, its variableneſs; and 3d, the productions dependent on it."

With regard to the firſt, it is remarked, that "from the high degree of north latitude in which this country is placed, one would not, at firſt, he ſays, ſuppoſe that its air ſhould be naturally mild; yet, on being compared with the temperature of other countries in the ſame parallel of latitude, it is certainly entitled to this character. The city of Moſcow, about half a degree ſouth of Edinburgh, is very different in point of climate. In the former city, ſo rigorous is the winter, that it is not uncommon for people to periſh by cold; the lips, noſes, ears, and fingers, of the inhabitants, are frequently froſt-bit; and water, thrown from a window, falls on the ground in ice; ſuch ſevere effects of cold may be ſaid to be unexperienced in the latter city, or in any part of the iſland. The iſland of Newfoundland, a diſtant branch of the Britiſh empire, lies in a lower latitude than England, and yet the extreme colds in winter, and the exceſſive heats in ſummer, render it very diſagreeable to the inhabitants. The ſame holds in regard to Canada, though ſituated in the 48th degree of north latitude: the climate, in point of mildneſs, is not equal to that of the mother country. Nay, in point of mildneſs, Britain excels lands on the continent, which one would think ſhould have naturally enjoyed a ſofter climate. We hear, with ſurpriſe, of the great falls of ſnow, the ſevere and long-continued froſts, the ſudden tranſition from theſe to ſultry heats, exceſſive rains, deſtructive hurricanes, and tremendous thunder-ſtorms, lightenings, and earthquakes, which ſcourge thoſe countries, whoſe inhabitants we are ready to envy, on account of their favourable climate; while, unconſcious of our own happineſs in this reſpect, we little think, that, in general, we breathe a purer air, untainted by noxious vapours, and fiery particles, that engender diſeaſe and death. In winter, too, our bodies are ſeldom ſo cramped with cold, or, in ſummer, ſo relaxed by heat, as to unfit us for paſtime or labour. This ſingular felicity of this iſland, as to climate, may be accounted for from its connection with the ocean. That immenſe body, from being always in motion, from never freezing, and from conſtantly inhaling the rays of the ſun, poſſeſſes a conſiderable degree of natural warmth. Of conſequence, the vapours exhaled from the ſea, by the action of the ſun, and which neceſſarily partake of the ſame warmth, when they mingle with our atmoſphere, muſt ſoften the coldneſs of the air. This is effected more eſpecially by the ſouth-weſt winds, which are prevalent in this country. Theſe, by the time they have croſſed the Atlantic, and reached our coaſts, muſt be charged with thoſe nutritive principles and genial vapours, which, being impregnated with the colder air of this iſland, deſcend in gentle dews and rains, that fertilize the ſoil. The ſame holds, though not in an equal degree, in regard to the wind that blows from the north, though colder than the weſt wind, in as much as it proceeds from countries nearer the pole; yet, in paſſing over the ocean it imbibes a portion of its warmth; and, when it reaches the country, is comparatively warmer than when croſſing the frozen mountains of the north. Hence, the reaſon why ſnow ſeldom lies above a few days on lands adjacent to the ſea-coaſt; hence, too, the influence of ſea-breezes, operating with other internal cauſes, namely, the natural fertility and warmth of the ſoil, the extenſive woods and plantations, with thoſe canals and rivers that carry off ſuperfluous water, the high ſtate of cultivation, the many cities, towns, villages, houſes, and animals, all combine in tempering the climate of this iſland; inſomuch, that it cannot be ſaid that, in any part of the iſland, high lands excepted, the climate is ſo intemperate as to prevent graſs growing, grain ripening, or the inhabitants from enjoying the comforts of life. Upon the whole, it appears, that a happy concurrence of circumſtances renders the climate of this country milder than that of other countries, which, from their local ſituation on the globe, might be expected to enjoy a more deſireable temperature."

In conſidering the ſecond diſtinction of climate, he remarks, that, "like the ocean that encompaſſes the iſland, our climate has been repreſented as inconſtant, unſettled, varying in the ſpace of a few hours, from dry to moiſt, from heat to cold, from clear to cloudy, and from the moſt pleaſant ſerenity to all the violence of tempeſt. He muſt, indeed, (he ſays), be an enthuſiaſtic admirer of the climate of Great Britain, who can give it a preference in point of uniform ſteadineſs to the climates of ſome continental countries. It muſt be admitted, that Britain does not enjoy that permanency of clear air and warm weather, nor that agreeable viciſſitude of ſeaſons peculiar to ſome kingdoms; nor is this poſſible, without the ſubverſion of thoſe laws which regulate ſeaſons and their changes. Upon the principles already laid down, it is obvious, that the iſland of Great Britain, waſhed upon three ſides by immenſe bodies of water, muſt neceſſarily be affected thereby; and it is impoſſible that its climate ſhould be ſo uniformly ſteady as that of other countries, ſituated in the centre of a vaſt continent, and ſheltered by ranges of mountains from the frequent inclemencies of winds and waves. To ſuch natural cauſes muſt be aſcribed the ſudden and frequent variations of our climate, felt at times ſo

 uncomfortably

uncomfortably by the natives; and which draw from those habituated to more constant climes heavy complaints against our atmosphere. "These irregularities of climate, however disagreeable, (he says), lay a foundation for advantages more substantial than any that result from a more pleasant and steady temperature of the air. It is not in countries where the seasons of heat and cold, wind and rain, are periodical, or where the greatest regularity of climate takes place, that mankind are most vigorous, or the fruits of the earth most perfect. There is a sameness of climate as well as of other things that is prejudicial to man. Besides, the air, from being long acted upon by heat or cold, moisture or dryness, is put into a state no less unfriendly to vegetable than animal tribes. But in Britain, the air, from being refined and quickened by the frequent changes it undergoes, is in little danger of being affected by such causes. In spring, it must be admitted, that the country is frequently drenched with rain, and the seed-time, of course, interrupted. But, excessive as the rains sometimes are, their bad effects are generally prevented by the keen sharp winds and dry air that quickly follow, insomuch, that a few days after it cannot be known that such weather had prevailed. It accordingly seldom happens in Britain, that the active husbandman is prevented by the inconstancy of the weather, from ploughing the land and sowing the seed in season. Seldom is that seed killed in the earth, or when sprung withered in its tender blade, either by untimely frost or inclement winds. In summer, the verdure of our hills and luxuriancy of our crops are seldom blasted by a long continuance of dry, scorching weather, or immoderate falls of rain. Sunshine and shade, genial warmth and moisture, succeed in grateful variety, and render our summer no less delightful to man than friendly to vegetation. The climate in harvest resembles that of spring, the weather suddenly shifting from ripening showers and mild sunshine to heavy clouds and sudden bursts of rain, that seem to threaten the promised harvest. Yet often when the heart of the husbandman is ready to despond, he beholds the season return in all its beauty, and has reason to acknowledge with gratitude the truth, that seed-time and harvest have not failed.

From autumn to the end of the year, the climate of Britain, is, he says, most variable, and its inconstancy is the more ungrateful from the advanced period of the season. Then the days, as well as nights, are liable to frequent changes, veering between frost and thaw, snow and rain, clearness and fogs; while often obscure and joyless rains descend, which deform the face of nature, and depress the spirit of man; yet it should be remembered, that these rains fall at a period when the fruits of the year are secured, when nature reposes (with the husbandman) after labour, and when, from the shortness of the day, little can be done without, and men are disposed to enjoy comfortable society within doors. Philosophers also maintain, that our rains in consequence of proceeding more immediately from the ocean, are more pure, and more impregnated with salts, than the rains which fall in most other countries; and though sometimes falling in prodigious quantities, yet tend to fertilize the soil. The climate of Britain in winter partakes of the same variableness that distinguishes it in other seasons. Sometimes the weather is open and mild; at other times frost sets in, and is succeeded by heavy falls of snow which cover, for weeks, the surface of the earth. However much the inhabitants may then suffer from the inclemency of cold, it is generally understood that the effects of frost and snow are, upon the whole, friendly to vegetation. Frost, by expanding the water or moisture contained in the soil, separates the particles of earth from each other, and thus renders the soil more loose, tender, and friable, than it would have otherwise been. This holds especially in regard to tough clay, upon which frost acts with a salutary effect, by reducing its stubborn nature and rendering it more fit for vegetation. The snows so frequent in Britain during winter, tend in various ways to fertilize the soil. Our winter snows, by covering the roots of vegetables, such as rye, wheat, &c. preserve them from the killing colds of the atmosphere. By snow covering the surface of the earth, its heat is cherished. Upon the principles of those who make oil the food of plants, snow must necessarily, he thinks, be a great fertilizer of the soil, from the oily particles it contains. Besides, snow, when it melts, moistens and separates the soil which had been bound up by the frost, and, as its water tends to putrefaction, it must, independently of the nitrous particles with which it is supposed to be impregnated, be greatly in favour of vegetation. In fine, says he, if the climate of Britain be less agreeable than some others, it has more variety." See Snow.

In regard to the influence of climate on the productions of the country, it is supposed that it is "from these the excellence or the defects of climate must be ascertained. These are evidences to which a safe appeal may be made. They are not, like natural causes, liable to be mistaken or misrepresented, but are open to the inspection of all. The productions dependent on climate, are plants, flowers, trees, grain of all kinds, nay animals, such as men, horses, cattle, sheep, &c. Upon a fair comparison of these with similar productions of other climates, a just estimate of the excellence of the climate may be formed. It is true, the author says, that there are fruits of various kinds that cannot arrive at maturity in Britain. Some natives of the torrid zone, when imported here, quickly languish and die; others, when introduced with much fostering care, may thrive for a season, yet from the influence of the air are soon stinted in their growth, and degenerate. But such fruits in general contribute only in a small degree to the subsistence of those who enjoy them, and may be regarded rather as luxuries than necessaries of life. Wheat, barley, oats, peas, beans, rye, cattle, sheep, swine, poultry, &c. are the great articles which constitute the food of man; and these our climate is calculated to produce in plenty and perfection. Upon the whole, from the comparative mildness of our climate, from its varieties, by no means unfriendly to vegetation and the perfection of fruits, and from the productions which depend on it; it appears that in regard to this first and great natural advantage of a country, Great Britain has been favoured in a considerable degree."

With respect to the climate of Middlesex, it has been suggested by Mr. Middleton, that "the temperature of the atmosphere, except, perhaps, so far as the influence of the London fires extends, is nearly the same through the whole county, there being no situation so much elevated as to produce the cold and thin air that we find in mountainous countries. In general it is healthy, owing to the greater part of the soil being naturally dry; and the more moist situations, being well drained, are consequently free from those unhealthy vapours which usually arise from stagnant waters. The fires of London, in which are consumed about 600,000 chaldrons of coals annually, have a sensible effect on the climate in its neighbourhood, by drying and warming the atmospherical air; which, being thus rarefied by heat, constantly passes upwards and makes way for a fresh supply to come in from every side. The most stationary winds are from the south-west and the north-east; all others are variable and unsettled. Those from the south-west are supposed to blow nearly $\frac{6}{12}$ths of the year,' and those from the north-east

east about $\frac{5}{12}$ths. The varying winds blow from all the other points of the compass about the other one-twelfth. Perhaps, he adds, it would be more accurate to say that winds from various points at and nearly the south-west blow about 25, north-east 20, and, from the rest of the circle, nearly seven weeks in every year. The winds seldom blow with so much force in this district as to shake the grain out of the ripe ears of the standing corn. The greatest falls of rain generally come from the south, and are most certain when the wind has passed through the east to the south. In the spring-months the damps on low grounds are sometimes congealed by cold, when there is no such appearance on the hills, and thereby some of the young shoots of the more tender shrubs and plants are destroyed in the former, when no injury happens to those in the latter situation. So great have been the extremes of heat and cold at some particular times, that on the 16th of July, 1793, the thermometer rose as high as $83\frac{1}{2}°$, and on the 24th of January 1795, it fell down to six degrees below 0; though this, perhaps, is the greatest difference in respect of climate ever observed in this kingdom; happily, however, it never continues more than a day or two at such extremes. The salubrity of any district is certainly affected, in a great degree, by the state of the soil and shape of the surface of such district; and hence it follows, that the natural climate of most or all countries may, unquestionably, be considerably improved by using the means best calculated to procure an equable degree of shelter, dryness, and moisture; all which may be effected in bleak, dry, and comparatively barren situations, by dividing them into small inclosures with broad hedge-rows and plantations, in belts of several yards wide; and in low flat situations, by draining off the stagnant water, by enlarging the inclosures, thinning and clipping the hedge-rows; in some instances by grubbing up not only these hedge-rows but also copses, woods, and plantations; thus removing every obstruction to a free circulation of air. This will necessarily absorb and carry off the redundant moisture, and consequently render the climate salubrious and comfortable. Indeed too much attention cannot, he says, possibly be paid, in cases of inclosures, plantations, &c. to the grand articles of drainage and shelter, and also to the nature and situation of the soil; as by a proper regard to these objects, not only the healthiness of the climate, with respect to animals, will be promoted, but the fruitfulness of the soil will be increased in a degree not otherwise to be expected."

It has been fully shown that much advantage may, in many cases of the culture of the soil, be derived from an intimate acquaintance with the nature of the climate, especially as, in the improved state of the art of agriculture, many of its operations are bestowed upon such plants as are exotic to the situation in which they are cultivated. The want of the knowledge of properly adapting the management of different articles of culture to the changes of climate has been often productive of disappointment and failure in such cases as might otherwise have been of great benefit and importance to mankind. Daily experience fully shows that the vegetable productions of one climate may, by proper attention, be readily naturalized in another. The advances of agriculture, in this way, have been great, but much still remains to be effected, which a better knowledge of the nature of climate may have the tendency of greatly facilitating and bringing forward.

CLIMATURE, a word sometimes employed in much the same way with climate. It is a term frequently made use of by some agricultural writers, as Mr. Marshall, in his "Rural Economies of the different Counties of the Kingdom."

CLIMAX, in *Ancient Geography*, a mountain of Asia, in Pisidia, near the town of Selga. It advances towards the sea of Pamphylia, leaving only a narrow passage, through which Alexander on foot conducted his army, according to Plutarch and Strabo.—Also, a mountain of Asia in Phœnicia, placed by Strabo between the river Adonis and the town of Biblos.—Also, a mountain of Arabia Felix, according to Ptolemy.—Also, a castle of Asia, in the maritime part of Galatia.—Also, a place of Peloponnesus, in Arcadia, near the town of Mantinæa, according to Pausanias.—Also, a place of Africa, in the nome of Libya, between Pednopum and Siropum, according to Ptolemy.

CLIMAX, or *gradation*, in *Rhetoric*, a figure, whereby the discourse ascends, as it were by degrees. Such is that of Cicero to Catiline: "Nihil agis, nihil moliris, nihil cogitas; quod ego non audiam, quod etiam non videam, planeque sentiam;" "thou dost nothing, movest nothing, thinkest nothing; but I hear it, nay see it, and perfectly understand it." Thus, the same Cicero to Atticus: "Si dormis, expergiscere; si stas, ingredere; si ingrederis, curre; si curris, advola." See ANTICLIMAX.

CLIMBER, in *Botany*. See CLEMATIS.

CLIMBERRIS, or AUGUSTA, in *Ancient Geography*, formed from *Climberrum*, and called by Mela *Elimberris*, the capital of the Ausci in Gaul.

CLIMBERTUM, or GLINIBERRUM, a place of Gaul, between Lactura and Belsino.

CLIMBING PLANTS, in *Gardening*, are such plants as ascend either spirally round supports, or by means of claspers and tendrils. They are either herbaceous or woody; and which, according to their mode of climbing, may be denominated *twining* climbers, *cirrhous* climbers, and *parasitic* climbers.

The first sort includes all such as have winding stalks, and twist about any neighbouring support, such as scarlet kidney-beans, hops, and some sort of honeysuckle.

The second kind comprehends all such as ascend by means of spiral strings, issuing from the sides of the stalks and branches, or from the foot-stalks of the leaves, and even from the leaves themselves, twisting about any thing they meet with, by which their stalks are supported and arrive at their proper height, such as most of the pea tribe, cucumber, vine, passion-flower, and various others.

And the last plants are also of the same kind, but their claspers plant themselves as roots in the bark of the plants on which they ascend, or in the crevices of walls or pales, thereby supporting themselves, and mounting to their tops, as the ivy, Virginia creeper, radicant bignonia, and several others.

Some of these sorts of plants, both of the herbaceous and shrubby kinds, are very ornamental. The principal of the herbaceous kind are, the everlasting-pea, painted-lady-pea, scarlet and white kidney-bean, nasturtium, gourd, hop-plant, scarlet convolvulus, &c. but there are many others.

The chief of the shrubby kinds, or such as have perennial stalks, are, the radicant and ever-green bignonia, climbing celastrus, different species and varieties of virgin's-bower, kidney-bean-tree of Carolina, ivy, Virginia creeper, many sorts of honeysuckle, passion-flower, many varieties of periwinkle, the vine, &c. but there are several others.

Many of the herbaceous climbers are very ornamental, and may be introduced in large borders, placing sticks for their support. The more tall growing sorts may also be employed to run over arbours or rural seats in pleasure-grounds, and other similar purposes.

The shrubby sorts are most of them proper furniture for shrubberies of considerable extent, in which they may be employed in different ways; some being dispersed in the clumps

clumps, detached from other plants, placing tall, ſtrong ſticks for their ſupport; others placed in large borders and the boundaries of lawns, &c.; and ſome near hardy trees and large ſhrubs, to climb about their ſtems, or interweave in their branches and tops; in the ornamenting of naked or unſightly walls and other high buildings; and in decorating and forming rural arbours, where there is any kind of open-work for the branches to climb upon. They are likewiſe very uſeful, as they ſhoot very rapidly, and ſoon cover ſuch diſagreeable objects.

Theſe ſorts ſhould, many of them, be kept properly cut during the autumn and early ſpring months; that they may not ſpread out too much, and injure other plants that are near them.

CLIMIA of the Arabs. See Klimia.

CLINA, in *Ancient Geography*, a fountain of Aſia Minor, in the Leſſer Myſia; near the town of Cyzicus.

CLINCH, in *Geography*, a mountain of America, in the ſtate of Tenneſſee, which divides the waters of Holſton and Clinch rivers.

Clinch, or Peleson, a river of America in the ſtate of Tenneſſee, being a navigable branch of the Tenneſſee river; it riſes in Virginia, and, after its entrance into the ſtate of Tenneſſee, it receives Powel's and Poplar's creek, and Emery's river, beſides other ſtreams. Its courſe is S.W. and S.W. by W. through Powel's valley, an excellent tract of country, abounding with fine ſprings. Its mouth, which is 150 yards wide, lies 35 miles below Knoxville, and 60 above the Hiwaſſee. It is boatable upwards of 100 miles.

Clinch *of a cable*, in *Sea Language*, is that part of it which is bent about the ring of the anchor, and then ſeized or made faſt.

Inſide clinch is when the end of a cable is paſſed through the hawſe-hole, and reeved through the ring of the anchor; then paſſed round the ſtanding part, through the bight, and a circle, which is called the "clinch," formed of the ſame ſize as the ring of the anchor; a throat and end-band are then clapped on oppoſite each other, and a ſeizing of ſpun-yarn cloſe to the end. All other inſide clinches are ſtopped, ſimilar to the bends of this clinch, with ſmall rope or ſpun-yarn.

Outſide clinch only differs from an inſide clinch, by paſſing the end on the outſide, and not through the bight, for the more readily caſting it off.

Clinch *bolts*, in a ſhip, are ſuch as are clinched, or clenched, with a rivetting hammer at thoſe ends which come through. See Clenching.

CLINCHER-*work*, or Clinker-*built*, the diſpoſition of the planks in the ſide of any veſſel, by which the lower edge of every plank overlays the next under it, like the ſlates on the top of a houſe.

This term is applied to boats that are covered with feather-edged boards lapping over each other; ſuch are generally ſharp-heads and ſterns.

CLINCHAMPS, in *Geography*, a town of France in the department of the Calvados; 5 miles S. of Caen.

CLINCHING, in *Sea Language*, a kind of ſlight calking uſed about the ports, on a proſpect of foul weather; it is done by driving a little oakum into their ſeams, that the water may not come in at them.

CLING, in *Geography*, a town and caſtle of Germany, in the circle of Bavaria, 4 miles E.N.E. of Waſſerburg.

CLINGEN, or Klingen, a town of Germany, in the circle of Upper Saxony, and county of Schwartzburg; 16 miles N. of Erfurt.

CLINIAS, in *Biography*, a Pythagorean philoſopher and muſician, who flouriſhed 524 years before Chriſt. As he was of a very choleric diſpoſition, he is ſaid to have aſſuaged his paſſion by his lyre.

CLINIC, κλινικος, formed from κλινη, a *bed*, a term applied by ſome *Church-hiſtorians* to thoſe among the ancients who received baptiſm on their death bed. It was the doctrine of many of the fathers, that baptiſm abſolutely waſhed away all previous ſins, and that there was no atonement for ſins committed after baptiſm. On this account many deferred that ſacrament till they were arrived at the laſt ſtage of life, and were pretty ſafe from the danger of ſinning any more; and ſuch were called *clinici*.

Magnus, in the third century, made a doubt whether or not clinics were truly baptized, in regard the ceremony was only performed by aſperſion, inſtead of immerſion; he conſulted St. Chryſoſtom on the point, who replied to him, that the ſacrament does not waſh away ſin after the manner of a corporal bath; and ſhews from ſcripture that aſperſion is ſufficient. See Baptism.

Clinic, or Clinical, is an epithet applied, in *Medicine*, to every thing which relates to the treatment and obſervation of diſeaſes, at the bedſide of the ſick. Hence the terms clinical practice, clinical lecture, &c. Clinical lectures, or thoſe lectures which are given upon the caſes of diſeaſe, the progreſs of which has been daily obſerved and regiſtered at the bedſide of the patient, conſtitute the moſt valuable mode of teaching the art of medicine.

CLINKERS, among *Brick Makers*. See Brick.

CLINO, in *Geography*, a town of European Turkey, in the province of Theſſaly; 22 miles W. of Zeiton.—Alſo, a town of Germany, in the biſhopric of Trent; 22 miles W.N.W. of Trent.

CLINOIDES, in *Anatomy*, an epithet given to the four ſmall proceſſes of the *os* sphenoides, one of the bones of the cranium; ſo called, ſay ſome, from their reſembling the feet of a bed.

The word is formed of the Greek κλινη, *a bed*, and ειδος, *form*; either from the reſemblance which the three bones bear to the feet of a bed; or from the cavity they form, which reſembles a bed itſelf.

Theſe together form a little cavity, from its ſhape called *ſella turcia*, or *equina*; wherein is placed the pituitary gland.

CLINOPODIUM, in *Botany*, (κλινοποδιον, Dioſc. Beds-foot, ſo called from the flowers growing in whorls one above another, like the old-faſhioned, turned feet of beds.) Tourn. 92. Linn. Gen. 725. Schreb. 980. Willd. 1115. Juſſ. 115. Vent. vol. ii. p. 342. Claſs and order, *didynamia gymnoſpermia*. Nat. ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ. Vent.

Gen. Ch. *Cal.* Perianth one-leafed, cylindrical, ſlightly curved, two-lipped; upper lip wider, trifid, acute, reflexed, lower lip divided, ſlender, inflexed. *Cor.* one-petalled, labiate; tube a little longer than the calyx, gradually widened into the throat; upper lip erect, concave, obtuſe, emarginate; lower lip trifid, obtuſe, middle ſegment wider, emarginate. *Bractes* numerous, about the length of the calyx, forming an involucre beneath the whorl or head. *Stam.* filaments four, two longer covered by the upper lip; anthers roundiſh. *Piſt.* Germ ſuperior, four-parted; ſtyle filiform, ſtigma ſimple, acute, compreſſed. *Peric.* none. *Seeds* four, naked, attached to the bottom of the permanent calyx, which becomes a little expanded below, and contracted near the orifice.

Eſſ. Ch. Bractes numerous, forming an involucre under the whorl or head.

Sp. 1. C. *vulgare*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Flor Dan. tab. 930. Lam. Ill. Pl. 511, fig. 1. Eng. Bot. 1401. (C. *origano ſimile*; Bauh. Pin. 224. Tourn. 195. Acinos; Lob. Ic. 504. Wild baſil. "Whorls hairy;

hairy; bractes briftle-fhaped; pedicels branched; leaves flightly ferrated." *Root* perennial, fibrous or fomewhat creeping. *Stems* fomewhat undulated, but not regularly zig-zag. *Leaves* petioled, egg-fhaped, rather obtufe, a little hairy, with veins regularly fringed. *Flowers* purplifh rofe-coloured, whorled, whorls terminal and axillary, few many-flowered; pedicels hairy; bractes hairy, fhorter than the calyx; calyx ribbed, hairy; two lower teeth longeft and moft prominent; corolla twice as long as the calyx, handfome, with two hairy knobs at the orifice; fegments of the lower lip rounded. The whole herb is aromatic, with a faint thyme-like odour. Dr. Smith. A native of England and other parts of Europe, on the borders of woods and in dry hilly fituations; flowering in June. There is a variety raifed by feeds from Canada which differs only in having flowers much fmaller. Two other varieties were fent to Miller from Carolina by Dr. Dale; the firft, which he calls *humile*, is not more than half the fize of the European fort, dividing into many long fide-branches; leaves fmaller and rougher; whorls more numerous, with longer bractes; flowering in June and July. The fecond, which he calls *carolinianum*, has ftems almoft round, the joints four or five inches afunder, with two oblong leaves at each, hairy on their under fide, on fhort petioles; at the bottom of thefe there is a flender branch on each fide, half an inch long, having two or four fmall leaves fhaped like the others. The flowers are white, in fmall whorls, ftanding thinly; bractes longer than the calyxes. It flowers in Auguft. 2. C. *ægyptiacum*, Lam. 2. Willd. 2. (C. vulgare *β*, Linn. Sp. Pl. 3. Mill.) "Whorls axillary, diftant leaves nearly entire, with a fmooth furface." Lam. Nearly allied to the preceding, but conftantly fmaller, lefs villous and more branched. *Root* perennial. *Leaves* ovate, acute, a little ciliated at the edge, with a tint of violet when young. *Flowers* pale red, or flefh coloured; whorls fmall, loofe, hifpid. A native of Egypt. Defcribed by La Marck from a living plant. Willdenow, who profeffes alfo to defcribe from a living plant, afferts that the flowers are never in whorls, but always in terminal heads. 3. C. *incanum*, Linn. Sp. Pl. 2. Mart. 2. Lam. 3. Willd. 3. (C. menthæ folio, incanum; Dill. Elth. 87. tab. 74. fig. 85. C. majus virginianum; Morif. Hift. 3. p. 374. Scot. 11. tab. 8. fig. 4. C. Serpentaria dicta; Pluk. Mant. 51. tab. 344. fig. 7.) "Leaves tomentous underneath; whorls flatted; bractes lanceolate." *Root* perennial. *Stems* two or three feet high, erect, obtufely quadrangular, clothed with a fhort whitifh pubefcence, branched near the top. *Leaves* oppofite, petioled, acutely egg-fhaped, toothed, green above, whitifh underneath, refembling thofe of mint; thofe next the flowers almoft always hoary. *Flowers* pale red, fprinkled with purple fpots, in two or three axillary whorls near the top of the ftem; upper lip fhort, entire. A native of Maryland, Virginia, and Carolina, flowering in Auguft.

CLINOVO, or Kliuno, in *Geography*, a town of Turkifh Dalmatia, generally ufed as a place of rendezvous in a time of war, and a depôt of arms and provifions; 30 miles E.N.E. of Spalatro.

CLINTON, the moft northern county of the ftate of New York in America, bounded on the N. by Canada, E. by the deepeft waters of lake Champlain, which line feparates it from Vermont, and S. by the county of Wafhington: feated on the lake Champlain and lake George, or lying about midway between Quebec and New York, at the diftance from each of about 230 to 240 miles. It is divided into 5 townfhips, *viz.* Plattfburg, the capital, Crownpoint, Willfborough, Champlain, and Peru. The length from N. to S. is about 96 miles, and the breadth from E. to W., including the line upon the lake, is 36 miles. In 1796 the number of inhabitants was eftimated at 6000, of whom 624 were intitled to be electors. The lands are generally of an excellent quality, and produce abundance of the various grains cultivated in other parts of the ftate. The inhabitants manufacture earthen ware, pot and pearl afhes, in large quantities, which they export to New York or Quebec. Their wool is excellent; their beef and pork inferior to none; and the price of ftall-fed beef in Montreal, 60 miles from Plattfburg, is fuch as to induce the farmers to drive their cattle to that market. The forefts fupply them with fugar and molaffes, and the foil is well adapted to the culture of hemp. The land carriage from any part of the country, in tranfporting their produce to New York, does not exceed 18 miles, the carrying place at Ticonderoga is 1½ mile; and from Fort George at the S. end of the lake of that name, to Fort Edward, the diftance is but 14 miles; after which there are fome fmall obftructions that are to be removed by the northern canal. From this country to Quebec are annually fent large rafts; the rapids at St. John's and Chamblee being the only interruptions in the navigation;

tion; and these are not so great, but, at some seasons, batteaux with 60 bushels of salt can ascend them. Salt is sold here at half a dollar per bushel. The rivers which water this [illegible] Boquet: the first of which [illegible] with spears and small scoop nets. [illegible] is usually caught here from May to November; it supplies excellent salted provision, and every cottager, by spending an hour in the evening, may obtain a sufficient quantity for his family. In this country ducks, geese, pigeons, and other kinds of birds are plentiful.

Clinton, a township in Dutchess county, New York, situated above Poughkeepsie, which is large and thriving. It contains 4607 inhabitants, including 167 slaves, and 666 are electors. — Also a settlement in Tioga county, New York, bounded by Fayette on the N., Warren on the S. Green on the W., and Franklin in Otsego county on the E. At the N.E. corner Unadilla river joins the Susquehannah, and the confluent stream runs S.W. to Warren.—Also, a plantation in Lincoln county, and district of Maine, 27 miles from Hallowell.—Also, a parish in the township of Paris, 7 miles from Whitestown, which is a wealthy, pleasant, flourishing settlement, containing several handsome houses, a newly erected Presbyterian meeting-house, a convenient school-house, and an edifice for an academy delightfully situated.

Clinton's *Harbour*, lies on the N.W. coast of N. America, having its entrance in N. lat. 52° 12'. W. long. 136°., so called by captain Gray after governor Clinton of New York.

CLIO, in *Mythology*, one of the *Muses*, daughter of Jupiter and Mnemosyne, the goddess of memory, who presided over history. The name is derived from κλεος, *glory*, or from κλειειν, to *celebrate*. In the portraits of Apollo and the Muses, dug out of Herculaneum, Clio appears seated, and her head is crowned with laurels. In her left hand she holds an open volume, in which she is reading. On the outside is written ΚΛΕΙΩ ΙΣΤΟΡΙΑΝ, *Clio the Historian*; though it should rather be translated, *Clio invented History*. At her feet are six other rolls, or antique volumes, inclosed in a cylindrical case. She is sometimes represented with a lute in one hand, and in the other a plectrum, or quill. Mr. Spence gives the following account of her "Clio presided over the noblest kind of poetry; her office was to celebrate the actions of departed heroes; who, therefore, has a roll, or book, in her hand, or else the longer holds a pipe, as in the relievo of the Muses in the Justiniani palace at Rome. Horace, in speaking of this pipe, seems to give it the shrillness of the trumpet, and, indeed, it is shaped much in the same manner with the trumpet, which the modern artists give to their figure of Fame. As Pindar, and several of the other old Lyric poets, dealt so much in celebrating the actions of departed heroes, this Muse may, perhaps, have been sometimes represented with a lyre too; though I do not remember to have seen any instance of it in the remains of the old artists. Statius makes her descend to lower offices, as if she must preside over any thing written in heroic verse; and his mistake, for it seems to be one, may be easily accounted for, from their looking formerly on every thing in hexameters as an epic poem." See Muses.

Clio, in *Zoology*, the name of a genus of worms, belonging to the order of *mollusca*: the body of which is oblong, and formed for swimming, and furnished with two opposite *alæ* of a membranaceous structure: it has three tentacula, besides two in the mouth. Gmelin enumerates 6 species, *viz* Caudata, Pyramidata, Retusa, Borealis, Helicina, or snail slime-fish, and Linacina: all of which are found in the ocean

CLIP, in *Rural Economy*, a word used to signify shearing sheep. And it also signifies the produce of wool, as the clip of any year implies the quantity that is afforded in it. See Sheep and *Shearing of* Sheep.

CLIPPING, the act of shearing sheep. This sort of business was formerly done in a longitudinal direction, but a later improvement is that of executing it in a circular method. It also signifies a sheep-shearing. See Sheep and *Shearing of* Sheep.

Clipping the *Coin*. See Coin.

CLISOBORA, in *Ancient Geography*, a town of India, placed by Arrian among the principal towns of the Surcenians. Pliny says that the river Jomanes passed between this town and Methora.

CLISSA, in *Geography*, a fortress of Dalmatia, taken from the Turks by the Venetians in 1684: 10 miles N. of Spalatro.

CLISSON, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Nantes, seated on the Sevre; 5 leagues S.E. of Nantes. The place contains 1178, and the canton 6139 inhabitants: the territory includes 140 kiliometres and 7 communes. N. lat. 47° 5'. W. long. 1° 23'.

CLIST, a river of England, which runs into the Ex, a little below Exeter.

CLISTHENES, in *Biography*, an Athenian magistrate, who flourished 510 years B.C. and introduced the mode of banishing by *Ostracism*; which see.

CLITÆ, in *Ancient Geography*, a town of Asia Minor in Bithynia, according to Ptolemy; situated towards the N.E. of Amastris.—Also, a place of Greece situated, according to Livy, near mount Athos, in Macedonia.—Also, the surname of the inhabitants of Cilicia Campestris, according to Tacitus; who says that they occupied the parts near the sea, and mount Taurus, in that district of Asia, which was subject to Archelaus, king of Cappadocia. When this king compelled them to pay tribute, they retired to mount Taurus, where they maintained themselves under their chief Trosobor against the troops which he sent against them.

CLITERIUM, or Clitorium, according to Pliny, a town of the Peloponnesus, in Arcadia.

CLITERNIA Larinatum, a town of Italy belonging to the Trentani, E. of Larinum, according to Pliny and Mela.

CLITERNUM, a town of Italy, situated in the country of the Equiculi, according to Ptolemy. Pliny calls the inhabitants Cliternini.

CLITHEROE, in *Geography*, a borough and market town of Lancashire, England, stands on the verge of that county, where it joins with Yorkshire, and is distinguished by its bold and insulated rock of limestone crowned with the keep of an ancient castle. At the northern extremity of the town, is an old mansion called the Alleys, which was formerly the manor-house, and was surrounded by a deep moat. The town of Clitheroe is an ancient borough by prescription, and made its first return of members in the first year of Elizabeth. The right of election is vested in a peculiar kind of burgage-tenure, and the number of electors is forty-two. Here are a weekly market on Saturday, and three annual fairs. The township contains 319 houses, with 1368 inhabitants, and is 217 miles north of London. Whitaker's history of Whalley, 4to.

CLITIS, in *Ancient Geography*, a river of Gaul, supposed by some to have been the Clain.

CLITOMACHUS, in *Biography*, a native of Carthage, who, fond of learning in his early years, visited Carthage for the

the purpose of attending the schools of the philosophers. At Athens he became the disciple of Carneades, and succeeded him in the chair of the New Academy. By diligent study he made himself master of the systems of the other schools; but professed the doctrine of suspension of assent, as it had been taught by his predecessor. Cicero says, that he wrote 400 books upon philosophical subjects. At an advanced age he was seized with a lethargy; but when he in some degree recovered his faculties, he said, "the love of life shall deceive me no longer," and laid violent hands upon himself. He held the office of preceptor in the Academy from the death of Carneades for 30 years, or till the 170th Olympiad, 100 years B. C. According to Cicero, he taught, that there is no certain criterion by which to judge of the truth of those reports which we receive from the senses; and that, therefore, a wise man will either wholly suspend his assent, or decline giving a peremptory opinion; but that, nevertheless, men are strongly impelled by nature to follow probability. His moral doctrine established a natural alliance between pleasure and virtue. He was a professed enemy to rhetoric, and thought that no place should be allowed, in society, to so dangerous an art. Brucker's Hist. of Philos. by Enfield, vol. i. p. 253.

CLITON, or CLITOR, in *Ancient Geography*, a river of Greece, in the Peloponnesus. It ran through Arcadia, and passed near the town of Clitor, according to Pausanias.

CLITONES, the eldest, and all the sons of kings. This word is often met with in our ancient authors.

CLITOR, in *Ancient Geography*, a town of the Peloponnesus, in Arcadia, seated on a river of the same name, S.W. of Lussi; about 60 stadia from the springs of the river Ladon. Pausanias says that Clitor, a very powerful sovereign, built it, and gave it his own name. The principal temples of this town were those of Ceres, Æsculapius, and Castor and Pollux. These two last were denominated there "the great gods;" and their statues were in bronze.

CLITORIA, in *Botany*, (from κλειω, *claudo*, *includo*, expressing the manner in which the essential organs of fructification are enclosed or shut up in the keel and wings of the corolla. Whatever may have been in the thoughts of Petiver, by whom the name was first introduced into botany; or of the illustrious naturalists, by whom it has since been continued, reformed, or sanctioned, we cannot refrain from entering our decided protest against every attempt to associate it directly with an anatomical term, to which, though derived from the same Greek theme, it has in fact only a very remote, factitious analogy. It is greatly to be lamented, that a fondness for these gross allusions should ever have been indulged by any, who, in all other respects, have deserved highly of natural science, and whose splendid talents should have rendered them far superior to such grovelling ideas. By this conduct they have done all in their power to pollute a study, which is, perhaps, more than all others, suited to the loveliest part of the human race, and which, without concealing any essential part of the sexual system, may easily be so conducted, as not to excite an unpleasant sensation in the most delicate female mind. We do not mean to exempt from the full severity of this censure our great master, Linnæus, himself; for when, not only the purity of moral feeling, but also the common decorum of polished life, is infringed, the *nullius in verba* of the poet will, we trust, be uniformly our principle and our practice.) Linn. Gen. 869. Schreb. 1183. Willd. 1352. Gært. 866. Juss. 357. Vent. 3. 404. (ternate, Tourn.) Class and order, *diadelphia decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss. Vent.

Gen. Ch. *Cal.* Perianth one-leafed, erect, tubular, five-toothed, permanent. *Cor.* papilionaceous; standard very large, straight, slightly emarginate, obtuse, covering the other petals; wings oblong, shorter than the standard, straight, obtuse; keel shorter than the wings, curved like a sickle. *Stam.* nine, united, one separate; anthers simple. *Pist.* Germ very long, superior, oblong; style ascending; stigma obtuse. *Peric.* Legume very long, linear, generally compressed, two-valved, terminated by an awl-shaped point. *Seeds* numerous, kidney-shaped. Corolla resupinate, or inverted.

Ess. Ch. Standard very large, covering the wings.

Sp. 1. C. *ternatea*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Lam. Ill. tab. 609. Gært. tab. 149. fig. 3. (Phaseolus indicus; Comm. Hort. 1. p. 47. tab. 24. Flos clitorides ternatensium; Breyn. Cent. 76. tab. 31. Flos cæruleus, Rumph. Amb. 5. p. 56. tab. 31. Ternatea, Tourn. Act. 1706. p. 84.) "Leaves pinnated; leaflets inversely heart-shaped; involucre two-leaved, roundish," Lam. "Leaves quinate-pinnated; peduncles axillary, one-flowered," Willd. *Root* perennial. *Stem* four or five feet high, herbaceous, twining, slender, branched. *Leaves* alternate, unequally winged; leaflets five or seven, veined underneath; with two bristle-shaped stipules at the base of each pair of leaflets, and two awl-shaped ones at the origin of the common petioles. *Flowers* large, blue, with a yellowish spot at their centre, generally solitary, on short peduncles. *Legumes* three or four inches long, narrow, lenticular-compressed, without knots, or risings above the seeds, terminated by the longish awl-shaped style, divided transversely into many cells; partitions thin, formed from the internal white cellular membrane of the valves. *Seeds* solitary, from seven to twelve, ovate kidney-shaped, truncated at one end, rather compressed, somewhat gibbous on both sides, smooth, chestnut-brown, Lam. and Gært. A native of the East Indies and Cochinchina; but the seeds were first brought to Europe from Ternate, one of the Molucca islands. There is a variety, figured by Rheed. Mal. 8. p. 69. tab. 38. with white flowers, and obtuser leaflets, in which the flowers generally grow from three to five together, in small axillary racemes. There is also a blue variety, with double flowers, an exuberance not common in this class of plants. 2. C. *heterophylla*, Lam. 2. Desfont. Annals of Botany, vol. i. p. 124. Ventenat Jard. de Cels. tab. 26. "Leaves pinnated; leaflets quinate; some rounder, some lanceolate, some linear," Lam. *Stem* above six feet long, branched, climbing, filiform, slightly pubescent. *Leaves* alternate, lower ones ternate, middle and upper ones pinnated with an odd leaflet; leaflets from seven to nine, small, smooth, opposite, terminated by a bristle-shaped appendage, not unfrequently emarginate; stipules awl-shaped. *Flowers* azure blue, resupinate, axillary, solitary, pendulous; peduncles a quarter of an inch long, very slender, slightly tumid at the summit; bractes four; two lower; two others superior, forming a kind of involucre to the calyx, very small, acute; calyx tubular, somewhat widened upwards, marked with five small prominent lines, terminated by five egg shaped, acute teeth, the three upper ones the largest; standard elongated, streaked, convex outwards, emarginate at the tip, longer than the wings; wings brought close together, obtuse, with a very slender claw; keel not sharp, formed by two contiguous petals, each borne on a pedicel; style somewhat geniculate; stigma pubescent, obtuse. *Legume* about two inches long, linear, smooth, sleek, flattened; pendulous, many-seeded, ending in a point; valves twisting spirally after they have opened. *Seeds* from eight to ten, compressed. Desfont. A native of the East Indies, found by Sonnerat; and of the isle of France, whence it was introduced into the French gardens by seeds brought by M. Cossigny. 3. C. *multiflora*, Willd. 2. Swartz. Prod. 106. "Leaves pinnated; pairs of leaflets many,

many, filky underneath; racemes axillary, many-flowered." *Root* perennial. A native of St. Domingo. 4. C. *Brasiliana*, Linn. Sp. Pl. 2. Mart. 2. Lam. 3. Willd. 3. (Planta leguminosa brasiliana, Breyn. Cent. 78. tab. 32.) "Leaves ternate; calyxes solitary, campanulate." Linn. *Stem* five or six feet high, twining. *Leaves* alternate on long petioles; leaflets ovate-oblong, flightly veined, rather hard. *Flowers* large, purple, axillary, solitary, peduncled; standard much broader, and wings larger than in C. ternate; leaflets forming the involucre of the calyx two, oval, opposite, membranous; bractes on the peduncle of the same shape. A native of Brasil. There is a variety with double flowers raised by Miller from seeds sent from India, but now lost in the English gardens. 5. C. *calcarigera*, Salisb. in Paradisus Londinensis, tab. 51. (C. virginiana, Linn. Sp. Pl. 3. Mart. 3. Lam. 4. Willd. 4. Brown. Jam. 298. Swartz. Obs. p. 282. Clitorius alter trifoliatus, Clayton in Gron. Fl. Virg. ed. 1. p. 73. —— Fœnum græcum phaseloides, Pluk. Alm. p. 175. Phyt. tab. 90. fig. 1.) "Leaves ternate; calyxes in pairs, campanulate." Lam. "Leaflets in one pair, terminated by an odd one; standard swelling at the back into a solid spur, which presses upon the claw." Salisb. *Root* perennial. *Stem* about three feet high, twining, slender, hairy. *Leaflets* egg-shaped, hairy, especially near the margin. *Flowers* in short spikes or racemes, seldom more than two-flowered; bractes striated; calyx much shorter than in other clitorias, scarcely compressed. Standard externally of a dull yellow colour, pubescent; internally lilac, with a yellow middle variegated with red streaks, smooth, furnished with a solid spur just above the claw; wings and keel pale lilac, adhering closely together; nectary very large, like a ruffle. *Legume* narrow with prominent sutures. *Seeds* brown, with a greyish cloud in the middle. A native of Virginia and the West Indies. There is a variety, with narrow elongated leaves; and another with ovate oblong ones figured by Dillenius. Hort. Elth. vol. i tab. 76 Mr. Salisbury observes, that though the leaves of this and the following species are said by Linnæus to be ternate, they are truly pinnated; for though consisting only of a single pair of leaflets beside the odd one, the two are placed upon the common petiole. Notwithstanding our general unwillingness to change trivial names, we have been induced to adopt Mr. Salisbury's as clearly expressing a character peculiar to the species. 6. C. *mariana*, Linn. Sp. Pl. 4. Mart. 4. Lam. 5. Willd. 5. (Clitorius marianus, Petiv. Sicc. 243. n. 55. Gron. virg. p. 83.) "Leaves ternate; calyxes cylindrical." Linn. Stem about five feet high, twining, weak. Leaflets narrower than in the preceding species, grayish underneath. *Flowers* axillary, of a pale blue colour within, whitish without; standard large. *Legumes* long, pointed, a little inflated. *Seeds* roundish. A native of North America. 7. C. *falcata*, Lam. 6. (Phaseolus, Plum. MSS.) "Leaves ternate; peduncles long, with about three flowers; legumes narrow, fickle shaped." *Stems* twining, flender, very long. *Leaves* alternate; leaflets ovate, of a pleasant green colour, resembling the leaves of the orange tree. *Flowers* large, bluish or purple violet; calyx oblong, almost funnel-shaped, with five acute segments, and an involucre resembling another calyx at the base. *Legumes* narrow, compressed, with several apparent articulations. *Seeds* kidney-shaped, shining, white with a red umbilicus. Plum. MSS. A native of St. Domingo. 8. C. *galactia*, Linn. Sp. Pl. 5. Mart. 5. Lam. 7. Willd. 6. Brown. Jam. 298. tab. 32. fig. 2. (Phaseolus, Sloane Jam. 1. p. 182. tab. 114. fig. 4.) "Leaves ternate; raceme erect; flowers pendulous. *Stem* about six feet high, twining, weak. *Leaflets* elliptic-oblong, obtuse, sometimes emarginate. *Flowers* reddish; calyx short, campanulate, four-toothed; corolla a little papilionaceous; all the petals oblong, narrow; standard a little larger than the others. *Legume* flender, cylindrical, pointed. A native of Jamaica, milky in all its parts. This species differs from all the preceding in the form and disposition of its flowers, which rather diverge from the generic character.

Clitoria *foliis pinnatis, caule decumbente*. Hort. Cliff. Gron. Virg. See Galega *virginiana*.

Propagation and Culture. All the species are annual in England, so that unless the seeds ripen they are lost, till they can be renewed by fresh seeds from their native climate. The seeds should be sown in a good hot-bed early in the spring, and the plants, when two inches high, should be transplanted into pots, and treated like other similar exotics. As they have climbing stalks, they will soon grow too tall for the common hot-bed, they must therefore be removed into the stove, and plunged into the bark.

CLITORIDIS *musculus*, in *Anatomy*, a name given by Verheyen to the muscle of the female *pudenda*, usually called *erector clitoridis*. This is the only muscle that is proper to this part; the other, called the *inferior clitoridis*, being properly a *sphincter vaginæ*, or, as Albinus calls it, *constrictor cunni*.

CLITORIS, one of the external organs of generation in the female sex. See Generation, *Organs of*.

CLITORIUS, in *Botany*. See Clitoria.

CLITOW, in *Geography*, a town of Bohemia in the circle of Pilsen, celebrated for its rich silver mines.

CLITUMNO, a river of Italy, which passes by Spoleto, and joins the Tepino between that town and Perugia, anciently *Clitumnus*. The Clitumnus, according to Pliny, (l. viii. ep. 8.) was a fountain with many veins between Hispellum and Spoletium, from which at a small distance arose a large and navigable river. Near it was an ancient and much revered temple, in which the god Clitumnus was placed, in a Roman habit, and where he issued oracles which manifested the presence and power of the divinity. Round him were arranged several small chapels, some of which had fountains and springs; for Clitumnus was the father of many other rivulets which join him. A bridge separated the sacred part of his waters from the profane; above this bridge people were allowed only to pass in boats; but below it they were permitted to bathe. This river flowed into the Tinia, now Tupino, and both together into the Tiber. It was famous, according to Virgil, (Georg. l. xi. v. 1447.) for its milk-white flocks and herds.

CLITUS, in *Biography*, an intimate friend of Alexander the Great; the brother of his nurse, who followed him in his conquests, and preserved his life by cutting off the hand of Rosaces, when he lifted up an axe to kill him at the passage of the Granicus. Clitus, to whom Alexander was affectionately attached, being invited to supper with the prince, and heated with wine, inveighed against adopting the customs of the Persians, and degraded the exploits of Alexander, in order to magnify those of Philip, his father. Alexander was so enraged that he struck him to death with a dart; but soon recollecting himself, he regretted the loss of his friend with such grief, as to fast three days and to form a purpose of starving himself to death: but, by the intercession of his friends, he was dissuaded from executing his purpose. Clitus was buried by Alexander in a very pompous manner.

CLIVE, Robert, baron Plassey, a celebrated English general, was born in the year 1725, at Styche, in Shropshire. During the years devoted to education he exhibited no taste for literature, but was characterised for a daring and adventurous spirit, almost incapable of restraint, and destitute of fear. When he was about 18 years of age, his father obtained for him the place of writer in the East India Company's pany's ſervice, and he arrived at Madras in the year 1744. In 1746 Madras ſurrendered to the French, and all the company's ſervants were made priſoners. The French commander in chief refuſing to ratify the terms of the capitulation, the Britiſh conſidered themſelves juſtified in breaking their parole; and among others, Mr. Clive, diſguiſed as a Moor, made his eſcape. Shortly after, he entered into the military ſervice, for which his temper and mind were well adapted, and in which he diſplayed great talents. He obtained, in the year 1747, an enſign's commiſſion in the Company's ſervice, and behaved with great valour at the ſiege of Pondicherry. He quickly obtained the rank of lieutenant, and in an attack upon fort Devi Cotah, he ſolicited the command of the forlorn hope, though out of his turn. His requeſt was granted, and, at the head of about 30 Britiſh troops and 700 Sepoys, he advanced to ſtorm the breach. The Sepoys inſtantly fled, but the lieutenant and his handful of men puſhed on, and had ſcarcely arrived at the breach, when the enemy ruſhed upon them with ſo much fury, that three only, with their commander, eſcaped inſtant deſtruction. The whole column of European troops then advanced to the attack, lieutenant Clive ſtill in the firſt diviſion, and the fort was reduced. Peace immediately followed. He returned to the civil eſtabliſhment, and was ſoon appointed to the office of commiſſary to the troops. In 1751, Clive reſumed the military character, with a captain's commiſſion, and in this capacity he was employed to attack the city of Arcot, having under his command 210 Europeans, and about 500 Sepoys. Such were the reſolution, ſecrecy, and diſpatch, with which he conducted the enterpriſe, that the enemy knew nothing of his motions until he was in poſſeſſion of the capital, which ſurrendered without a blow. The inhabitants, expecting to be plundered, offered him a large ſum to ſpare the city, but they derived their ſecurity from the generoſity of the conqueror. He refuſed the proffered ranſom, declaring that thoſe who choſe to remain in the city ſhould be protected, and that the others might retire with all their effects, excepting proviſions, for which he promiſed to pay the full value. By this wiſe conduct he ſo conciliated the affections of the people, that they became his ſteady friends, and ſupplied him with exact intelligence of the enemy's deſigns. The town was ſoon inveſted by Raja Saib, at the head of a numerous army, and the operations of the ſiege were conducted by European engineers, but when they came to make their general aſſault, they were repulſed in every quarter with great loſs, and obliged to raiſe the ſiege with the utmoſt precipitation. On this relief captain Clive took the field, and was uniformly ſucceſsful over the enemy. After he had ſubdued all the force oppoſed to him, he returned to Madras, and from thence in 1753 he embarked for England. He was received with every demonſtration of reſpect and gratitude by the Eaſt India Company, who preſented him with a very valuable ſword richly ſet with diamonds. His ſtay in England was but ſhort, and he returned to India governor of St. David's, with the rank of lieutenant-colonel in the king's ſervice. After performing ſome important ſervices, he went to Madras in order to take the command of a ſuccour to be ſent to Bengal, where the nabob Dowlah had declared war againſt the Engliſh, deſtroyed their factories, and taken Calcutta. At this city and period the horrid tragedy of the black-hole was acted. See CALCUTTA.

Admiral Watſon and colonel Clive determined to revenge the cruelties inflicted on their countrymen at Calcutta. The admiral with his fleet proceeded up the river on the 28th of Dcember, and on the next day colonel Clive landed, and, with the aſſiſtance of the ſquadron, ſoon reduced and took poſſeſſion of the town. Clive then took the field with his force of 700 Europeans and 1200 Sepoys, and entrenched himſelf a few miles diſtant from Calcutta. The nabob immediately marched with an immenſe army, conſiſting of 20,000 horſe and 30 000 foot, beſides cannon and elephants, and encamped near Calcutta. Propoſals of peace were ſent to the Eaſtern prince; theſe being contemptuouſly rejected, colonel Clive determined to attack the nabob's camp, which he did with ſo much ſucceſs, as to oblige the nabob to ſue for peace; this was granted him upon terms highly advantageous to the intereſts of the Company. After the concluſion of the treaty, the Engliſh commanders proceeded to the attack of the French fortreſs and factory of Chandernagore, the reduction of which filled the nabob with new apprehenſions, and he threatened to join the French. The mutual injuries inflicted and ſuſtained between Sou-Rajah-Dowlah and the Britiſh being of ſuch a nature as to leave no room to hope for a continued peace, colonel Clive conceived the project of dethroning the nabob. In this ſcheme he had engaged Meer-Jaffier, a diſcontented courtier, who had retired from the palace to his reſidence in the country, from whence he tranſmitted diſpatches to colonel Clive, urging him to begin his march to Moorſhedabad. The colonel immediately put the whole army in motion, and with a firm reliance on his own talents, and on the valour of his troops, croſſing the Ganges, he advanced to Plaſſey, within a day's march of the capital, where he found the nabob encamped with a force of 70,000 men, in all the pomp of oriental magnificence. The number of elephants with their ſcarlet houſings;—the rich embroidery of their tents and ſtandards;—and the martial ſplendour of their cavalry, parading over the field with their drawn ſwords glittering in the ſun,—made a grand and awful, but very intereſting appearance. The nabob, on the firſt intelligence of the march of the Engliſh army, eagerly courted the ſupport and aſſiſtance of Meer-Jaffier, who took a ſolemn oath upon the Koran that he would be his faithful ſoldier. Though the army of the Eaſtern ſovereign was poſted on an eminence, colonel Clive advanced at the head of his troops, conſiſting of only about 3000 men, with great intrepidity to the attack. Such were the diſtruſt and deſpondency prevailing through the Aſiatic army, that ſcarcely any reſiſtance was made; and with a trifling loſs, in compariſon, of about 70 men, a moſt deciſive victory was gained; the camp, artillery, and ſtores of the enemy falling into the hands of the victors. Meer Jaffier, who commanded the left wing of the nabob's army, took no part whatever in the action, but at the cloſe of the day he came over to the Britiſh. The conquered nabob fled to his capital, where he was betrayed and put to death. Colonel Clive now entered Moorſhedabad as conqueror at the famous battle of Plaſſey. The inhabitants of the city were ſufficiently numerous to have deſtroyed the Engliſh army with miſſile weapons only, but they were ſo intimidated by the ſuperior valour of their enemies, that they offered the commander large ſums to ſecure their property, which he did not accept, conſidering himſelf bound to protect them without a bribe. For the Company, he received of Meer-Jaffier, whom he had raiſed to the vacant throne, a crore of rupees, amounting to more than a million ſterling, as an indemnification for their loſſes at Calcutta. He alſo ceded to the company a conſiderable territory in the vicinity of the city. In conſequence of the battle of Plaſſey, colonel Clive was made governor of Bengal. Shortly after this the great mogul conferred on governor Clive the title of omrah of the empire, and he received a grant from Meer-Jaffier of lands, to ſupport his new dignity, worth about 27,000*l* per annum. Having raiſed the Eaſt India Company's affairs from almoſt the brink of ruin, to a highly proſperous ſtate, and having himſelf become great in wealth,

 in

in rank, and in celebrity, the governor returned to his native country in 1760. The following year he was created an Irish peer by the title of lord Clive, baron of Plassey.

Owing to new disorders in India, and such changes as led the directors to tremble for the safety of their acquired territories in that country, they again applied to lord Clive to accept the presidency of Bengal, and the command of the troops in that province. In 1764 his lordship embarked for India, having been first created knight of the Bath. With him were associated four friends, whose powers were so extensive, that they surpassed and superseded every other authority in the Company's settlements. Before the arrival of lord Clive, affairs had taken such a turn, that the easy task devolved upon him of settling terms with the country powers, which he rendered very advantageous to the Company, who had now the disposal of all the revenues of Bengal, Bahar, and Orissa, deducting only about three hundred thousand pounds for the use of the emperor. Lord Clive then set about the more arduous undertaking of reforming the abuses among the Company's servants; he put the army establishment upon a better footing, and introduced some good regulations into the conduct of the private trade, which, nevertheless, were not so strict as to prevent oppressions among the natives.

In 1767, lord Clive returned to England, having contributed to the prosperity of the company in a most unexampled manner. Six years after this, a resolution was moved in the House of Commons to the following purport, *viz.* "That in the acquisition of his wealth, lord Clive had abused the powers with which he had been entrusted." By the assistance of Mr. Wedderburne, afterwards lord Loughborough, he defended himself against all the charges brought against him, which at one time put on a very serious aspect; at length the original motion was rejected, and it was resolved, "That lord Clive had rendered great and meritorious services to his country." Though he thus escaped a public prosecution, he, from this time, fell a prey to the most gloomy depression of spirits, which, it has been confidently said, resulted from the recollection of his misconduct in India, and which neither the wealth accumulated for his own use, nor the prosperity which he obtained for his employers, could ward off. At length, at the age only of 50, in November 1774, he put an end to his own life, leaving behind him five children and a widow, the sister of Dr. Maskelyne, the present astronomer-royal.

Lord Clive was of a reserved temper, but among particular friends he was cheerful and even jocular; and in domestic life he was kind and amiable. He had, as we have seen, the fine talent of inspiring confidence into those under his command;—hence he was characterised by the great lord Chatham "the heaven-born general, who, with little experience, surpassed all the officers of his time." He represented the town of Shrewsbury in parliament from 1760 to 1774, but rarely spoke in the house, though upon particular occasions he displayed great powers of elocution. By his will he bequeathed 70,000*l.* to the invalids in the Company's service.

CLIVERS, in *Botany*. See Galium *Aparine*.

CLOACA, formed from κλύζω, *I wash away*, among the *Ancients*, was a subterraneous aqueduct, or common sewer, for the reception and discharge of the filth of a city or house. Tarquinius Priscus is said (Liv. i. 38.) to have been the first who contrived *cloacæ* in ancient Rome, which extended under the whole city, and separated into various branches. The arches which supported the streets and buildings were so high (being in some places upwards of 100 feet), and so broad, that, as Procopius says, a man on horseback might easily ride through them, even in the ordinary course of the channel, and a wain loaded with hay might pass, and vessels sail in them. Hence Pliny calls them (xxxvi. 13.) "Operum omnium dictu maximum, suffossis montibus, atque urbe pensili subterque navigatâ." The principal sewer, now existing, with which the rest communicated was called "cloaca maxima," and was principally the work of Tarquinius Superbus (Liv. i. 56.). This was formed of large blocks of stone joined together without any cement, and covered with a triple vault composed of three ranks of voussoirs bonded with one another. It began in the Forum Romanum, measured 300 paces in length, and about fifteen feet in width, being in several places divided into three parts, forming a causeway on each side, and a channel in the middle; and emptied itself between the temple of Vesta and the Pons Senatorius. The cloacæ were at first carried through the streets; but through the want of regularity in rebuilding the city, after it was burnt by the Gauls, they in many places passed under private houses. There were as many principal cloacæ as hills. In the streets, at proper distances, were openings for the admission of dirty water, or any other filth, which persons were appointed always to remove, and also to keep the cloacæ clean. This was the more easily effected by means of the declivity of the ground, and the plenty of water with which the city was supplied. In the time of the republic, about 400 years after the completion of the original drains, they were repaired by Cato the censor, and his colleague, Valerius Flaccus, who constructed several new cloacæ in those parts of the city to which the old channels did not extend, as upon the Aventine, at an expence, according to Dionysius of Halicarnassus, of 1000 talents. Agrippa distinguished himself during his ædileship, by constructing cloacæ so long and numerous as to occasion the observation of Pliny above-mentioned.

The care and inspection of the cloacæ, which constituted one of the distinguished and most celebrated monuments of Rome, on account of the grandeur and utility of the work, as well as the enormous expence that attended it, belonged to the censors and the ædiles till the time of Augustus, who appointed "curatores cloacarum" on purpose; and a tax called "cloacarium" was imposed for keeping them in repair. The "servitus cloacæ" was the right of conveying a private common sewer through the property of a neighbour into the "cloaca maxima" of Tarquin. The Romans had also their Cloacina, or goddess, who presided over the cloacæ.

Cloaca, in *Comparative Anatomy*, imports that canal in birds through which the egg descends from the ovary in its exit. In this it is remarkable, that the part which is next the ovary is jagged, like the *morsus diaboli*, and fluctuates in the abdomen without any attachment to the ovary; hence anatomists have been somewhat puzzled to comprehend by what means the egg falls into the ovary. See Egg.

CLOAK Bay, in *Geography*, a bay on the N.W. coast of America, that separates Queen Charlotte's isles from North island; the middle of the entrance of which is situated in N. lat. 54° 10′. W. long. 133° 20′.

CLOATHING *the bolsters*, in *Rigging of Ships*, denotes laying several thicknesses of worn canvas well tarred over them, to make an easy bed for the shrouds.

CLOATHS, or Clothes. See Habit. By stat. 6. Geo. I. c. 23. the wilful and malicious tearing, cutting, spoiling, burning, or defacing of the garments or clothes of any person passing in the streets or highways, with intent so to do, is felony. This was occasioned by the insolence of certain weavers and others, who, upon the introduction of some Indian fashions prejudicial to their own manufactures, made it their practice to deface them, either by open outrage, or by privily cutting, or casting aquafortis in the streets upon such as wore them.

CLOCHE *Sujette a la Taxe Militaire.* From the moment a place that has stood the fire of cannon is taken, the inhabitants are obliged to re-purchase with money the bells of the churches and divers utensils of copper and other metals. The sum arising from this belongs to the commanding officer of artillery, who nevertheless frequently retains but a certain part of the said sum, leaving the remainder thereof to be divided in just proportions among the officers under his command. This at least used to be the case.

CLOCK, CLAAS, or NICHOLAS, in *Biography,* a painter and engraver, native of Leyden, and scholar of Francis Floris. Amongst his engravings, which are something in the stile of Cornelius Cort, though coarser in their execution, may be noticed a large print representing the judgment of Midas, from Carlo Van Mandere, dated 1589, and the four Elements, half figures, dated 1597, which are probably from his own designs. Heinecken. Strutt.

CLOCK, in *Horology,* is a machine which measures, subdivides, and indicates the successive portions of time with a degree of accuracy that has deservedly given it the preference over the clepsydra, and brought it into general use for civil, domestic, philosophical, and astronomical purposes; it is constructed of various materials, and after different models, to accommodate the views of various individuals; its value, therefore, varies from three half-crowns to one hundred pounds and upwards; but though every householder almost is now in possession of a clock, few individuals, comparatively speaking, know either the theory of its action, or the subserviency of the separate parts of its mechanism to produce their destined effect; and yet, no instrument has been more the object of ingenuity, or the subject of science, for two or three successive centuries, than the machine in question, before it attained its present most improved construction. Its name is derived either from the German *die gloke* or *die kloke,* a clock, or from the French *la cloche,* a bell, against which it usually strikes the hour indicated.

In tracing the records of antiquity for the origin of the first horological machine, that had a suspended gravitating body as a maintaining power, and a regulator of some determined shape and dimensions to check its velocity at small equidistant intervals, different authors have fixed upon different ingenious men as its inventor, and have quoted with some confidence passages from the more ancient writers in confirmation of their respective opinions: hence Archimedes and Possidonius before the Christian æra, Boethius in the fifth century, or about the commencement of the sixth, Pacificus about the middle of the ninth, Gerbert at the end of the tenth, Wallingford near the beginning of the fourteenth, and Dondi at the end of the fourteenth, have severally been asserted to have been the first contrivers of a clock. The difficulty of ascertaining the exact period when a regulated machine for measuring time without the assistance of water was first invented, arises from this consideration, which has not been sufficiently attended to; *viz.* the appellation *horologium* has by ancient writers been indiscriminately applied to all instruments that had any thing to do with hours, whether regulated or not, such as sun-dials, clepsydræ, and instruments for merely representing the motions of the heavenly bodies, like our orreries and planetaria; and, lastly, clocks, or machines with a bell, to strike the hours, placed in the steeple *(le clocher),* of some abbey.

The sphere of Archimedes, made two hundred years before Christ, as mentioned by Claudian, was evidently an instrument with a maintaining power, but without a regulator, and therefore would not measure time in any other way than as a planetarium, turned by a handle, measures, or rather exhibits, the respective velocities of the planetary bodies. The same may be said of the sphere of Possidonius eighty years before Christ, as mentioned by Cicero (De Natura Deorum), notwithstanding the deference which is due to the opinion of Dr. Derham.

When Bernardus Saccus (Hist. Ticin. lib. vii. c. 17.) ascribes the invention of clocks to Boethius in the year 510, he passes over that part of the quotation from Cassiodorus, which says, "that the hours were determined *guttis aquarum,* by drops of water;" hence his horologium was evidently nothing more than a clepsydra. The authority upon which Pacificus, archdeacon of Verona, has been deemed the inventor of clocks in the year 850, is the subjoined portion of his epitaph:

"Horologium nocturnum nullus ante viderat,
En invenit argumentum et primus fundaverat;
Horologioque carmen spheræ cœli optimum
Plura alia graviaque prudens invenit."

Professor Hamberger, in a paper read to the Society at Gottingen in 1758, (vide Beckmann, vol. i. page 419, & seq.) has given reasons for believing this "Horologium nocturnum," as it is called in opposition to a sun-dial, or horologium diurnum, to have been a clepsydra, notwithstanding the "nullus ante viderat," for it was in the ninth century that Hildemar, speaking of the Monks, in regard to their observing the hours, says, "he who wishes to do this properly must have "horologium aquæ," which is considered as a proof that clocks did not then exist. (Commentar. in Reg. S. Bened. cap. 8.) On the contrary, Bailly in his "History of Modern Astronomy" (vol. i. p. 321.) asserts, that Pacificus was the inventor of a clock going by means of a suspended weight, an escapement, and a balance; if this information be accurate, no doubt he was the first who is known to have made a clock; but F. Berthoud (Histoire de la Mesure du Tems, tom. i. p. 49.) very properly observes, that the celebrated author has adduced no authority for the assertion he has used, and that he believes it to be inaccurate. With respect to Gerbert, who was made pope Silvester II. in the year 999, Dithmar (Chron. lib. vi. p. 83. fol. 1580.) believes that his horologium was only a sun-dial which he made at Magdeburg; his words are "Gerbertus, a finibus suis expulsus, Ottonen petiit imperatorem, et cum eo diu conversatus, in Magdeburg horologium fecit, illud recte constituens, considerata per fistulam quadam stellâ nautarum duce." Here no wheels or weights are mentioned, but, on the contrary, his observation only of the pole-star, which assisted him in fixing the horologium or dial; nay, in Gerbert's book "De Astrolabio" he explains the method of erecting dials for all latitudes, but says nothing of any other kind of horologia. To what has been above remarked, concerning the different significations of the word horologium, may be added what is said by the anonymous author of the life of William Abbot of Hirshau, who lived in the eleventh century, *viz.* "naturale horologium ad exemplum cœlestis hæmisphærii excogitâsse," which expression alludes to some piece of astronomical mechanism at that time invented; and according to the account of Trithemius respecting the horologium made in 1232, and sent by the sultan of Egypt to the emperor Frederic II. (Chron. Hirsaug. ad. h. a.) as well as from Leland's description of Richard Wallingford's horologium, called Albion, (all by one) made in 1326, these must have been instruments classing rather with our orreries than our clocks; for the motions of all the heavenly bodies appear to have been conducted by the maintaining power, whatever it was, without any controlling or regulating mechanism. (Vide Tanneri Biblioth. Brit. Hibern. p. 629.) It may be further remarked here, that the words, "horolo-

gium

gium dirigere," "ordinare," temperare," &c., which denote the office of the facriftan, in the writings of the faid William Abbot of Hirfhau, evidently allude to the adjuftments of the clepfydra. Hence it may be fairly inferred, that no one of the preceding contrivers of horologia was alone the inventor of a regulated clock: the invention was, no doubt, of monaftic origin, or, at leaft, intended firft for monaftic purpofes, when the ftated periods of prayer required the attendance of the monks by night as well as by day. That the horologium of Dondi, however, was a clock can admit of but little doubt; it was conftructed at Padua about the end of the fourteenth century, by order of Hubert, prince of Carara; and the defcription given of it by Petrus Paulus Vergerius (in Vit. Princip. Carrar. ap. Murator. tom xvi. p. 171.) is this; "Horologium quo per diem et noctem quatuor et viginti horarum fpatia fponte fuâ defignarentur, in fummâ turri conftituendum curavit." This fpontaneous defignation of 24 hours of day and night, by an horologium, placed on the fummit of a turret or fteeple, correfponds exactly to our church-clock; but ftill it remains uncertain whether or not Dondi, who was afterwards called Horologius, was the original inventor. About the middle of the fourteenth century feems then to be the time that affords the firft certain evidence of the exiftence of a clock, or regulated horological machine, notwithftanding the frequent mention of horologia in preceding ages, as applied to other horological inftruments; and the following are fome of the earlieft authentic notices that hiftory has recorded on the prefent fubject.

1. In the "Chronica Mifcella Bononienfis" (in Muratori. tom. xviii. p. 444.) it is faid that the firft clock at Bologna was fixed up in the year 1356.

2. About the year 1364, Henry de Wyck or Henri de Vic, a German artift, placed a clock in the tower of Charles V.'s palace. (Vide Moreri. Diction. art. Horloge du Palais.)

3. In Rymer's Fædera is mentioned the protection of Edward III. to three Dutchmen, Orlogiers, who were invited from Delf into England in the year 1368, from which time we may probably date the introduction of clock-work into England.

4. Conradus Dafypodius has given an account of a clock erected at Strafburg about the year 1370.

5. According to Froiffard, Courtray had a clock about the fame period, which was carried away by the duke of Burgundy in the year 1382.

6. Lehmann fays that at Spire was a clock in the year 1395.

7. Nuremberg had a clock in 1462, Auxerre in 1483, and Venice in 1497; and it appears from a letter of Ambrofius Camaldulenfis (lib. xv. Epift. 4.) to Nicolaus of Florence that clocks began to be common in private familes on the continent, about the end of the fifteenth century. (Beckmann.) It is probable therefore, that clocks began to be general in England too about the fame period, for we find in Chaucer, who was born in 1328, and died, as is fuppofed, in 1400, the following diftich: *viz.*

> "Full fickerer was his crowing in his loge,
> As is a clock, or any Abbey orloge."

The honourable Daines Barrington (Archeologia, vol. v. p. 415.) is indeed difpofed to believe that clocks were in ufe at the beginning of the fourteenth century, and quotes the following paffage, as a proof, from the Italian poet Dante, who was born in 1265 and died in 1321.

> "Indi come horologio che ne chiami,
> Nel hora che la fpofa d'Idio furge
> Amattinar lo fpofo, perche l'ami."

But we have feen that clepfydræ were called horologia, which had alfo fometimes ftriking mechanifm; therefore the paffage before us will apply with equal propriety to that inftrument. The fame author alfo fuppofes that the clock-houfe, near Weftminfter Hall, was furnifhed with a clock in the fixteenth year of Edward I., or in 1288 (vide Selden's Preface to Hengham), out of a fine impofed on Radulphus de Hengham, chief juftice of the king's bench, but there appears to be more of conjecture than proof in the detail. From the teftimonies which have been here adduced refpecting the origin of a clock, the conclufion to be drawn is, that this machine is neither of fo ancient a date as fome writers fuppofe, nor yet among thofe more recent inventions which are placed in the laft two centuries; and that the inventor is not certainly known. Fer. Berthoud, who has written more volumes on the fubject of clock-work than any other man, concludes his refearches with a belief, founded in ftrong probability, that a clock, fuch as that of Henry de Wick, is not the invention of any one man, but an affemblage of fucceffive inventions, each of which is worthy of a feparate contriver: for inftance—1. Wheel-work was known in the time of Archimedes; 2. the weight applied as a maintaining power had at firft a fly, moft likely fimilar to that of a kitchen jack; 3. the ratchet wheel and click, for winding up a heavy weight without detaching the teeth of the great wheel, was found the next indifpenfable contrivance; 4. the regulation of the fly, depending on the ftate of the air, was abandoned, and a balance fubftituted; 5. an efcapement confequently became neceffary, which, in conjunction with the balance, conftituted a more regular check upon the tendency which a falling weight has to accelerate its velocity, than a fly ufed as a regulator could of itfelf be; 6. the application of a dial-plate and hand, to indicate the hours, was the confequence of the regularity introduced into the going part of the mechanifm; and, laftly, the ftriking portion, to proclaim at a diftance, without the aid of a watching-man, the hour that was indicated, completed the lift of inventions. Such a fucceffion of ingenious contrivances, introduced by different men, to improve upon the firft rude inftrument, is perfectly analogous to the fucceffive improvements which the prefent clock has experienced, at different periods, fince Henry de Wick's clock was conftructed, which is the moft ancient one of which we have a particular defcription.

Defcription of the Ancient Clock made by Henry de Wick.

Going Part.—Fig. 1, of *Plate* VIII. of *Horology*, reprefents, in profile, the movement of this clock, and *fig.* 2, the front view of the fame inftrument: A is a weight, fufpended by a chord, which is folded round a metallic barrel B, the arbor, *a a*, of which has its ends or pivots, *b*, *b*, paffing through fmall circular holes in the plates C C and D D, which, in this ancient clock, were of iron, the former being bent at right angles at the ends, and fcrewed to the latter, inftead of having pillars; thefe plates, when thus attached, conftitute what is called the frame.

The action of gravity of the weight, A, has a natural tendency to fall towards the earth, and to carry along with it the whole mechanifm, but the frame being fixed firmly on a fupport is fuftained in its place; inftead, therefore, of all the mechanifm being pulled from its fituation, the barrel, B, is pulled round to allow the cord to efcape, and would move with an accelerated velocity, according to the laws of falling bodies, if it had not the wheel, F, with inclined teeth, beft feen in *fig.* 5, pinned to it, which is called the ratchet wheel, and which has its motion ftopped by the fmall pointed piece of metal, *c*, called a click, inferting its pointed end into a fpace between two teeth, and kept to its place by a

flender

slender spring, *d*. This spring and also the click are screwed to the wheel G, as may be seen in *figs.* 1, 2, and 5, which is not fastened to the arbor of the barrel, consequently, when the weight pulls downwards, the ratchet wheel pushes the click, and with it the wheel G, but when the weight is taken off, and the ratchet wheel turned backwards, the wheel, G, keeps its position, by reason of the click sliding easily along the sloping sides of the ratchet wheel, which it is allowed to do by being made to move freely on its screw as a stud; this contrivance for moving the wheel, G, when the weight falls, and for leaving it at rest when the weight is raised, is the mechanism both for winding up the weight, which is called the maintaining power, and also for transmitting this power to the wheel, G, when wound up: but, as the suspended weight of this palace clock, of Charles V. of France, was too heavy to be wound up by the strength of one man, the wheel Q, *figs.* 1 and 2, was fixed on the same arbor with the barrel, and the pinion, *n*, was applied to it, to be turned by a handle or key taking hold of its square arbor at P, which additional wheel and pinion formed a kind of crane for elevating the weight, and the click held it in any state of elevation.

The wheel, G G, having the motion of the barrel communicated to it by means of the click, transmitted it to the pinion, *e*, *fig.* 1, and consequently to the wheel, H H, riveted on the same arbor *f f*; this wheel, H H, again transmitted the motion received to a lantern pinion, *g*, and consequently to the wheel, I I, fixed on its arbor, which was called the crown wheel or escapement wheel (roue de rencontre): this last wheel by giving the pallets or short levers, *h*, *i*, each a push alternately by two teeth, at opposite sides of its circumference, and moving in opposite directions, one forward and the other backward, gave a vibratory motion to the vertical arbor, K, moving on two pivots, *l*, *k*; and as the regulator or balance was fixed on this arbor, it was thus made to vibrate backwards and forwards at every push of the crown wheel upon the pallets, which alternate motions of the balance were called vibrations or oscillations, and their frequency was regulated by the small weights, *m*, *m*, better seen in *fig.* 2, placed at their corresponding distances on the arms, L, L, of the balance, by means of little equidistant notches: if the vibrations were too quick the momentum of the balance was increased by removing the small suspended weights farther from the centre of motion, and *vice versâ*. As the balance was necessarily heavy to counterpoise a large maintaining power, a slender cord, M, was suspended from a small cock, T, placed on the large cock, S, that preserved the perpendicular direction of the arbor K, which cord bore the principal weight of the balance, and suffered it to vibrate without the whole friction which its weight would have occasioned on the lower pivot.—The pallets were placed at about 90° from each other on the arbor or verge of the balance, so that when one of them was parting with its tooth of the crown wheel, the other was in a situation to receive the opposite one immediately; this action of the crown wheel upon the pallets, which escaped the teeth alternately, was called, and is still denominated, the escapement, or by abbreviation, 'scapement of the clock; it is by means of it that the large weight is prevented from falling with rapidity to the ground, by receiving a check at every impulse of the wheel of escapement on one or other of the two pallets; and the interval between two successive impulses was regulated by the time of a vibration of the balance, which period we have seen was adjustable. Thus the whole duration of a vibration was the measure of time, and the wheels and pinions were employed, first to transmit the maintaining power in order to overcome the obstacles to motion which the balance met with from friction and resistance of the air; and secondly to number the vibrations and indicate them in a visible form by a hand, O, *fig.* 2, on a dial plate, not given in the figures, as they amounted to hours. The former of these offices of the wheel-work we have already described without attending to the numbers of the teeth into which the wheels and pinions were divided; but to comprehend the nature of the latter office, this consideration must be taken into the account. The escapement wheel, I I, has one tooth completely escaping the pallets at two vibrations of the balance, which we will suppose adjusted to be exactly equal to as many seconds of time; then on this supposition, the escapement wheel of 30 teeth will make one entire revolution in 60", or one minute, as will also its pinion, *g*, of 8, by reason of its being fast on the same arbor; but as this pinion acts with the wheel, H H, of 60 teeth, only 8 of those teeth will pass the pinion in every minute, therefore as often as 8 are contained in 60, so many minutes will this wheel take to revolve in, which are $7\frac{1}{2}$; its pinion, *e*, of 8 also revolves in $7\frac{1}{2}$ minutes, on account of being on the same arbor, which pinion acts with the great wheel G G, so that eight of its teeth pass in $7\frac{1}{2}$ minutes; but its number is 64, or eight times eight, it therefore revolves in eight times $7\frac{1}{2}$ minutes, *i. e.* in one hour exactly: hence as often as the cord is wound round the barrel, so many hours will such a clock continue to go after winding. Now as the wheel, G G, revolves once in every hour, it is evident that the pinion, *d*, on its arbor, which projects through the frame, will turn round also in an hour. Its number of teeth is 8; therefore $8 \times 12 = 96$ is the number of teeth of the dial wheel, N N, which goes round along with the hand, *o*, placed on its arbor, in 12 hours. Thus while the train, as it is called, of wheels and pinions is transmitting the power of the suspended weight forwards to the balance, it is also counting back again the number of vibrations to constitute an hour, and pointing out on the dial plate, by the addition of a hand, each successive hour, as the vibrations accumulate. Should it be asked here, why a large weight is necessary to actuate the wheel-work, the answer is, that the power of it is gradually diminished as it approaches the regulator according to that law of dynamics, by which the force is known to be equal, whether a large weight moves with a small velocity, or a small weight with a proportionate great velocity, if there were no friction in the train, one sixtieth part of the weight, hung on a similar barrel placed on the crown wheel, would have the same effect on the balance, as the large weight itself in its present situation on the hour arbor; but then it would want winding up sixty times in the same period in which it requires only once winding up with a large weight falling with diminished velocity; so that convenience was the object to be attained in fixing upon a large maintaining power.

Clock Part, or *Striking Part*.—The striking, or what is properly called the clock part of the antique piece of mechanism, which we are describing, is, perhaps, the most ancient of any which is transmitted to us, and which therefore deserves a particular detail, especially as the ordinary Dutch clocks retain very nearly the same construction to this day. We cannot give a better idea of this portion of the instrument, than by translating F. Berthoud's account of it, from his "Histoire de la Mesure du Temps," as we have done, with some verbal deviations, in our description of the going part.

In *Plate* VIII. *figs.* 3 and 4 represent the wheel-work of the striking part, adopted in Henry de Wick's clock: A and B, *fig.* 3, are the principal plates, or rather bars of iron; C and D, the connecting parts instead of pillars; the weight F, suspended by the cord, that surrounds the cylinder G, is the maintaining power; and this cylinder has a rachet wheel fixed to it, like that in *fig.* 5, in the going part, and connected with a click faſtened to the wheel, H, *figs.* 3 and 4. for the purpoſe of winding up the weight; for performing which, a handle is put on the ſquare arbor of the pinion *a*, which acts with the remontoir wheel, I, faſtened to the cylinder. Wheel H has eight pins projecting from its plane [illegible], &c. which pins lift ſucceſſively a hammer that ſtrikes againſt the bell, which parts are not repreſented in the plate, but their principle may be readily conceived from the deſcription, which we ſhall hereafter give, of the ſtriking part of a modern clock. Wheel H drives the pinion *d* fixed on the ſame arbor with the wheel K, which again drives the pinion *e*, on the projecting arbor of which is fixed the fly L, the office of which fly is to regulate the interval between each blow of the hammer, which it does by means of the reſiſtance that its revolving wings, or fanners, meet with from the air.

The manner in which the reſpective number of blows of the hammer for each hour is regulated, is an ingenious invention, and is thus effected; the arbor of the firſt wheel, H, is made to project through the frame, ſo as to take a pinion, *f*, of eight leaves, to drive the wheel M of 78 teeth, which number is equal to 1 + 2 + 3 &c. + 12, or whole number of ſtrokes in 12 hours. On the wheel M is fixed another wheel, N, *figs.* 3 and 4, called the *count* wheel, which has 12 notches on the edge, at unequal diſtances, *viz.* at $\frac{1}{78}$, $\frac{2}{78}$, $\frac{3}{78}$, &c. of the circumference, correſponding to the hours 1, 2, 3, &c. to regulate the number of ſtrokes at each hour. Q, *fig.* 4, is a detent fixed on the arbor R of *fig.* 3, with its claw reſting on the edge of the count-wheel N; to which arbor a lever, T, is alſo fixed, reaching to the pins of the 12 hour wheel N of *fig.* 2, and likewiſe a ſhorter lever, V, within the frame directly above a ſingle tooth, *o*, on the arbor of the fly L. Now as the 12 hour wheel revolves by the going part, one of its pins catching the end of the lever T at every hour depreſſes it, and at the ſame time raiſes the claw or catch of the detent from the notch of the count-wheel, and alſo the ſhort lever V from its tooth *o*, by reaſon of the detent, and two levers, being all faſt to the ſame common arbor R; the weight F in this ſituation, makes the wheels run on till another notch of the count-wheel comes to the claw of the detent Q, when it again falls by the gravity of the load P, placed alſo on the ſame common arbor R, and filling the notch ſtops the count-wheel; at the ſame time, the ſmall lever V falls in the way of the tooth *o* of the fly, and arreſts the motion of the wheels within the frame; ſoon after which the fly alſo comes to reſt, partly by the reſiſtance of the air, and partly by a ſpring preſſing on the end of its arbor, round which it can revolve in a detached ſtate, like the fly of the chime mechaniſm, which we have before deſcribed.—The number of ſtrokes which the hammer makes when raiſed by the pins *b*, *c*, &c. depends on the diſtance between the two notches of the count-wheel, on which the claw of the detent reſts at the time. The ſame proceſs is repeated every time that one of the pins of the 12 hour wheel, depreſſes the end of the lever T, and detaches thereby the claw of the detent and tooth *o* of the fly arbor, ſo as to permit the weight F to actuate the wheel-work for the limited time of ſtriking.

We are not informed what are the numbers of teeth in the wheel-work of the ſtriking part contained within the frame, nor is it of much importance, as this movement has no other uſe, than that of regulating the reſpective velocities of the fly and pin wheel H, that raiſes the hammer; but when the wheel M has 78 teeth, as we have ſtated, it is neceſſary that the pinion *f*, that drives it, ſhould have juſt as many leaves as there are pins on the wheel H; otherwiſe one tooth of the wheel M would not correſpond to one ſtroke of the hammer againſt the bell, which is a neceſſary condition; the pinion *f* therefore has eight leaves, correſponding to the eight lifting pins of the wheel H, and 78 ſtrokes are given in a progreſſion increaſing by unity, during each twelve hours, after equal hourly intervals of ſilence.

Hiſtory of the ſucceſſive Improvements in Clocks.

The preceding account of Henry de Wick's rude clock muſt have prepared the reader for a deſcription of the ſucceſſive alterations and improvements which ingenious mechanicians and artiſts have deviſed in the clock during the laſt two centuries; for it muſt have occurred to him in the peruſal, that large iron wheels continually expoſed to the oxiding influence of the atmoſpheric air, in which unequal and ill ſhapen teeth were cut with the inaccuracy of a manual operation, were by no means calculated to tranſmit the maintaining power with perfect regularity to the balance, ſuppoſing it to have been a good regulator; but when it is further conſidered; that the alternate direct puſhes of the balance-wheel againſt the pallets muſt have produced jerks, and deſtroyed or greatly diſturbed the regularity of this moſt eſſential part of the mechaniſm, great accuracy was not to be expected in the indication of time; ſo that, as we ſee, even minutes were deemed too ſmall portions of time to be indicated by ſuch a machine. We find, notwithſtanding, that ſo early as the year 1484, Walther made uſe of a balance-clock for heavenly obſervations, as did the landgrave of Heſſe after him; and ſuch ſeems to have been the utility of the clock, thus early, for aſtronomical purpoſes, that Gemma Friſius propoſed a portable one to be uſed at ſea for aſcertaining the longitude by ſo ſoon as the year 1530. About the year 1560 Tycho Brahé was in poſſeſſion of four clocks, which indicated hours, minutes, and ſeconds, the largeſt of which had only three wheels, one of which was three feet in diameter, and had 1200 teeth in it, a proof that clock-work was then in a very imperfect ſtate. Tycho however obſerved, that there was an irregularity in the going of his clocks, which depended upon the changes in the atmoſphere; but he does not appear to have known how ſuch effect was produced. In the year 1577 Moeſtlin had a clock ſo conſtructed as to make juſt 2528 beats in an hour, 146 of which were counted during the ſun's paſſage over a meridian, or azimuth line, and determined his diameter to be 34′ 13″, ſo that the ſcience of aſtronomy began thus early to be promoted by the aſſiſtance of clock-work; and as clocks firſt promoted the ſtudy of aſtronomy, it will be ſeen by and bye that aſtronomy in its turn gave riſe to ſome of the moſt eſſential improvements in clock-work, and that, as the arts and ſciences were more and more cultivated, improvements in clock-work kept pace with them, and employed the talents of the moſt ingenious men of each ſucceeding age.

One of the firſt additions to the mechaniſm we have before deſcribed was what we call an alarum or larum, ſtill uſed in the Dutch wooden clocks, which contrivance took its origin from the circumſtance of prayers being uſed at ſtated periods in monaſteries by night as well as by day; the fervors of devotion were not found always unfettered by ſleep at the hour proclaimed by the bell, an invention conſequently became neceſſary to rouſe the ſleepy prieſt to his duty by a continued ringing in his ſtunned ears: for a deſcription of which mechaniſm we muſt refer to the article *Thirty-hours* CLOCK *with a Larum*.

It is not quite certain at what time exactly the bulky ſize of the ancient clock was reduced to a ſtate of portability, which muſt have conſtituted a real improvement, as the main ſpring muſt have been invented previouſly; the ſubſtitution of of which for a large heavy body, as a firſt mover, conſtituted a ſecond æra in horology, from which we may date the origin of the fuſee, or mechaniſm for equalizing the variable power of a coiled ſpring; and from which our modern watches and chronometers of great value derive both their form and principle.

F. Berthoud (Hiſtoire de la Meſure du Temps, i. 79.) ſuppoſes that a portable clock muſt have been invented ſome time before the year 1544, which was that in which the Corporation of Maſter Clock-makers at Paris had a ſtatute enacted in their favour by Francis I. to this purpoſe, *viz.* "No one, of whatever ſtation, if he be not admitted a maſter, ſhall make, or cauſe to be made, clocks, alarums, watches, large or ſmall, or any other machine for meaſuring time, within the ſaid town, city, and precinct of Paris, on pain of forfeiture of the ſaid works, and of arbitrary penalty, &c." This ſtatute, however, inſtead of proving the origin of portable clocks, only proves that in the year 1544 they had begun to be commonly made in France, and probably had been introduced from Germany, which country, no doubt, was the nurſe as well as mother of horology. Indeed we have lately been favoured with the ſight and examination of a portable clock, at preſent in the poſſeſſion of Mr. Peckitt of No. 50, Old Compton ſtreet, which, from an inſcription engraven in the Bohemian language, appears to be much older than the ſtatute above quoted: it was made in the year 1525 by Jacob Lech of Prague, and differs in its conſtruction from De Wick's clock, in that it has a ſpiral ſpring, with a fuſee of ſoft metal, and a ſcrew inſtead of notches at the ends of the double levers of the balance, with tapped weights of lead for the adjuſtment to time, with the addition of ſome wheel-work, to ſhew the motions of the ſun and moon, in an engraven ecliptic, and alſo a contrivance to ſtrike one at every hour. The wheels are of iron, and retain certain punched marks of diviſion which prove that they have been cut with a file by hand; and the levers being faſt to the arbor or verge of the pallets, will vibrate either in a horizontal or vertical poſition. A catgut was originally the band of the fuſee; but the introduction of a modern metallic chain unfortunately has deſtroyed nearly three out of the eight ſpiral threads at the ſmaller end, ſo that inſtead of going 48 hours, *viz.* ($8^{thr} \times 6^{h}$), the remaining five threads will allow the piece to go only 30 hours, or $5^{thr} \times 6^{h}$, which it now does, though irregularly, with vibrations of nearly one ſecond each by eſtimation. Beckmann, in his "Hiſtory of Inventions," mentions this clock as having been the property of Mr. Ferguſon, at whoſe ſale the preſent proprietor purchaſed it in the year 1777, and he intends, we underſtand, to bequeath it to the Britiſh Muſeum, where, no doubt, it will be conſidered as a great curioſity. On examination of the wheel-work, we found the moon's train to be $\frac{12}{6} \times \frac{82}{6} = \frac{984}{36}$ of a day $= 27^{d}\ 8^{h}$ for a periodic revolution, and the ſun's $\frac{984}{36} \times \frac{81}{6} = \frac{79704}{216} = 368$ days, the inaccuracies of which trains prove that planetary mechaniſm in clocks had at that period made no great progreſs towards perfection.

But the portable clock of which we have here given a ſhort notice, we have reaſon to believe, was not among the firſt that were made, for at firſt the ſpiral ſpring was folded in a box, the arbor of which had the great wheel on it, and the irregularity of its action was in ſome meaſure equalized by a ſecond ſpring, which, being diſpoſed in a certain curve, oppoſed the principal ſpring when wound up, and acted in the ſame direction with it when its intenſity began to remit; this piece of mechaniſm, which was a German invention, preceded the invention of the fuſee, and was called *ſtack freed*. Berthoud has given a drawing and deſcription of a portable clock, probably by Gourdain, without a fuſee; and ſome of the modern French watch-makers have probably borrowed from it their idea of making a watch go well without a fuſee. For the ſhape and uſe of which equalizer of irregular power, ſee the article FUSEE.

When the ſize and weight of a clock were reduced, the quantity of friction was ſo diminiſhed, as to allow the thread of ſuſpenſion, on the verge of the balance, to be abandoned, which circumſtance gave riſe to a new poſition of the balance, the verge of which was now placed horizontally upon its pivots, which were a little flattened, ſo that the weight might be ſupported by its edge; and this contrivance was called the *knife edge* ſuſpenſion, a ſpecies which F. Berthoud has pronounced ſuperior to the ſuſpenſion with a ſlender ſpring, to which the Engliſh artiſts are much more partial, though it does not appear that their partiality is founded on any thing like impartial experiment.

Such was the ſtate of clock-work when Galileo, the celebrated philoſopher and mathematician to the duke of Florence, obſerved, that two lamps, or other heavy bodies, ſuſpended by ſtrings of the ſame length, made their vibrations in long or ſhort arcs, very nearly, if not exactly, in the ſame ſpace of time; this iſochronal property he publiſhed at Paris in a treatiſe, called "L'Uſage du Cadron ou de l'Horloge phyſique univerſelle," in the year 1639, which explained, in 15 chapters, its uſe in philoſophy, aſtronomy, muſic, phyſic, &c. and though he never applied the pendulum as a regulator to ſuperſede the balance in clocks, yet we may date from his diſcovery a third æra in clock-work, namely, the origin of the pendulum clock, which continues in uſe in our day; the idea of the iſochroniſm of a detached pendulum at leaſt was his, and the inveſtigation of the law, by which bodies fall in free ſpace, was applied by him to determine the lengths of two pendulums, that ſhall vibrate in times that are in a given ratio to each other.

It has been a ſubject of great contention, who had the honour to be the firſt artiſt, or mechanician, who applied a pendulum to clock-work; without pretending to decide the conteſt, which, at this diſtance of time, can be determined only by hiſtorical evidence, we will briefly lay before the public the pretenſions of different men to this invention, and leave the reader to judge, from ſuch facts as we have been able to collect on the ſubject. Bernard, one of the profeſſors of aſtronomy at Oxford in the laſt century, has aſſerted, that the Arabians, beſides having clepſydræ and ſun-dials, made uſe of pendulums in aſtronomy long before this period, as we know Riccioli, Tycho Brahé, Langrenus, Vendelin, Merſenne, Kircher, Hevelius, Mouton, and Galileo himſelf, did in a detached ſtate; but we do not find that any of them uſed it in conjunction with wheel-work. According to Becker (Bailly's Hiſt. of Modern Aſtron.), Juſte Birge, a native of Switzerland, in the year 1552, and who was Rothman's ſucceſſor at the obſervatory at Caſſel, from 1590 to 1597, was the firſt who applied a pendulum to a clock, which application, however, he never publiſhed to the world, that we can learn, and which, therefore, if the fact be true, never benefited the world.

According to profeſſor Venturi (Eſſai ſur les Ouvrages phyſico-mathematiques de Leonard de Vinci), Sanctorius applied a pendulum to clock-work ſome time before the year 1625, in which he publiſhed his "Commentarii in Avicennam," and deſcribed ſeveral inſtruments which he had explained to his auditors 13 years before, in his lectures read at Padua.

Vincentio Galilei, ſon of the famous Galileo, is alſo ſaid

(Exper. de l'Acad. del Cimento) to have made a pendulum clock, suggested by his father's discovery, so early as the year 1649, at Venice; but Christian Huygens, the justly celebrated mathematician and philosopher of Zuylichem, contested the honour of priority of the application with him, which contest gave rise to that excellent treatise on clock-work, "De Horologio Oscillatorio," which laid the foundation of most of the subsequent improvements in horometrical machines, and in which it appears indubitably, that he made, or directed the making of, a pendulum clock before the year 1658. From comparing what has been adduced by these two contending mechanicians, an impartial reasoner is led to conclude, that Vincentio Galilei may have applied, in a rough mechanical way, not made generally known, such a pendulum to clock-work as proved no mean substitute for the balance; but that Huygens applied it in a more scientific and masterly manner, and probably without any knowledge of what his opponent had previously done; hence the honour of the invention, as it has been called, has been generally attributed to Huygens.

But whilst we have studiously avoided entering into a minute discussion of all the proofs that have been adduced in favour of each of these foreigners, to substantiate their respective claims to originality of project, with respect to the pendulum, we should act in opposition to our feelings as Englishmen, as well as to our professions of impartiality, if we did not here avail ourselves of some documents that have recently fallen into our hands, which bear the marks of authenticity, and from which it appears, that neither Vincentio Galilei, nor yet Huygens, was the first who adapted a pendulum to a clock, but that an artist in London, named Richard Harris, invented and made a pendulum clock about eight years before either of them dated their claims; an engraven plate, bearing date "Great Russel Street, Dec. 21, 1798," is at this time hanging in the vestry room of St. Paul's church, Covent Garden, of which the annexed is a verbal copy, *viz.*

"The (new) turret clock, and bells of this church, were made A.D. 1797, by Thomas Grignon, of Great Russel Street, Covent Garden, the son and successor of Thomas Grignon, who, A.D. 1740, brought to perfection what the celebrated Tompion and Graham never effected, *viz.* the horizontal principle in watches, and the dead-beat in clocks, which dead-beat is a part of the mechanism of the turret clock. Thomas Grignon, senior, made the time-piece in the pediment at the east end of this parish church, destroyed by fire A.D. 1795. The clock fixed in the turret of the said (late) church, was the first long pendulum clock in Europe, invented and made by Richard Harris of London, A.D. 1641; although the honour of the invention was assumed by Vincenzio Galilei, A.D. 1649, and also by Huygens in 1657. This plate is here affixed by Thomas Grignon of this parish, the son of the above Thomas Grignon, as a true memorial of praise to those two skilful mechanicians, his father and Richard Harris, who, to the honour of England, embodied their ideas in substantial forms that are most useful to mankind."

In order that the reader may judge for himself, what degree of credit is to be attached to the preceding memorial, the writer of the present article pledges his honour to the public, that the following extract, which, on inquiry, is Mr. Grignon's authority for attributing the invention of the pendulum to Richard Harris, is copied verbatim from a manuscript marginal note, written in page 12 of an old book, at present in his possession, called "Essayes of Natural Experiments made in the Academie del Cimento, under the protection of the most serene prince Leopol, of Tuscany, written in Italian by the secretary of that academy, and translated by Richard Waller, F.R.S. London, 1684."

(*Copy of the Extract.*)

"The great clock belonging to Covent-Garden, has a long pendulum, and was made by Richard Harris of London, in the year 1641, which was eight years before Vincenzio Galilei put his father's observations into practice, as appears by the date 1649.

"The ingenious Mr. Huygens applied the pendulum to a clock in the year 1657, and attributed the invention to himself, which created a dispute between him and Vincent Galileo; this last affirming that he had put it in practice in 1649; and the reason of Richard Harris's not appearing, (which would have decided the controversy,) in all probability was, that he being only a private workman was entirely unacquainted with any dispute which might happen between Vincent Galileo and Mr. Huygens; or he might be dead before the dispute arose, it being sixteen years after he made the said church clock."

The manuscript of which this is an exact copy bears every mark of the antiquity ascribed to it by the present Mr. Grignon, who is reputed to be a man of veracity, and who most positively asserts it to be his father's hand-writing, as indeed it appears to be, when compared with some other of his papers which we have seen. It may not be foreign to the subject to add here, that the late Mr. Grignon, who died on April 4, 1784, aged 71, was a good mathematician as well as an excellent workman, and was patronized by Archibald, duke of Argyle. He was an intimate friend of James Ferguson and other scientific men of his time, and one of the first members of the Society of Arts in London, to which society he presented a regulator in the year 1759, which is yet in one of the rooms at the Adelphi, and which has the improved dead-beat escapement, and very high numbers in the wheel-work to avoid friction, which was another idea of his own. The peculiar properties of this clock, however, seem not to have been noticed by, or even perhaps known to any of the present members of that numerous society, so as to become an object of particular attention. Mr. Grignon, notwithstanding, assures us, that it will keep the same time whether its maintaining power be four or twelve pounds, which property he ascribes principally to his father's improvement of Graham's dead-beat escapement.

From this account of Harris's clock, we confess ourselves disposed to contradict the generally received opinion, asserted by other authors, that Fromantil, the Dutchman, was the first who made pendulum-clocks in England so late as the year 1662; one of which was given by bishop Ward to Gresham College, Oxford. Indeed Dr. Hooke, as great a genius as any we have mentioned, made a pendulum-clock, we find, in 1658, for Dr. Wilkins, afterwards bishop of Chester, which was prior to Fromantil's clocks, and some authors have been disposed to make him the inventor of the pendulum as a regulator.

The pendulum being once applied to clock-movements, was found to be a regulator so much superior to the old balance, that Gemma Frisius's idea of making a marine or nautical time-piece was attempted to be realized by the ingenious Huygens, of which attempt we have already spoken under the word CHRONOMETER, where we entered into a detail of the merits and construction of various pieces of mechanism used for the determination of a ship's longitude. It may not be improper, however, to say further of Huygens' marine-clock, that its pendulum vibrated more slowly as it approached

proached the equator, proving, as Picard has fince afferted from experiments made in 1669, the fhape of the earth to be that of an oblate fpheroid. But Huygens, whofe induftry was equalled only by his ingenuity, foon difcovered that the ifochronal property afcribed to the pendulum by Galileo, was only true in circular arcs, when the length of the arc of vibration remained the fame; for that long circular arcs required fomewhat more time for a vibration than fhort ones, fo that variations in the maintaining power produced variations in the time indicated, by altering the length of the arcs of vibration. This difcovery prefented a ferious difficulty, and gave rife to one of the moft ingenious contrivances ever introduced in the mechanifm of a clock, though practical experience foon proved it to be of little or no ufe; we mean the contrivance of two cycloidal cheeks at the point of fufpenfion confidered as evolutes of a cycloid, round which the thread by which the pendulum was fufpended was bent, and occafioned, as we have before noticed under the word CHRONOMETER, the ball to move in the involute of the faid curve, which Huygens firft demonftrated to be itfelf a cycloid, poffeffing theoretically this peculiar property, amongft others, that a heavy body defcending along it from any given point therein, will defcend to the loweft part in the fame time that any other heavy body will fall from any other higher or lower point thereof; whence it was concluded, that a pendulum, vibrating in fuch a curve, would regulate a clock in the beft poffible manner with any maintaining power whatever. The idea was truly ingenious, and the mechanifm equally fo, as we have faid, in theory; nay, the pendulum really moved in a cycloid by this contrivance, but then the alternate pufhes of the balance-wheel againft the pallets were communicated by means of an intermediate lever, called the fork, (which was another invention of our author) to the pendulum, which additional force fo greatly difturbed the natural power of gravity, that the pendulum attached to clock-work was no longer poffeffed of the ifochronal property which it poffeffes when moving in a cycloid in a detached ftate, with all its weight collected in one point, as the theory fuppofes; befides, the moifture of the atmofphere affected the pendulum's ftring of fufpenfion, and what had not been obferved fufficiently at that time, the metallic rod itfelf elongated with heat, fo that the cycloidal cheeks were at length found to be of no benefit as an auxiliary to the natural pendulum, and have therefore been abandoned.

After the length of a fecond's pendulum was afcertained by Huygens to be 3 feet $8\frac{1}{2}$ lines, old French meafure, and after he had propofed it as an univerfal ftandard of meafure, we find that aftronomers began to afcertain the right afcenfion of the ftars by it, and alfo the equation of time, that Hipparchus had fpoken of long before, which application made it neceffary that there fhould be fome contrivance for winding up the maintaining power of the clock during the time that it continued to go, otherwife the quantity of the earth's rotation, that might take place during the act of winding up, muft have been allowed for by conjecture; hence the endlefs chain with a detached ratchet, was invented for this purpofe by Huygens, which is ftill in ufe, we believe, in fome few aftronomical clocks. The fame author was probably the contriver of our prefent dial-work, for changing the hour into 60 minutes by the addition of another hand at the centre of the clock-face; and a circular pendulum was likewife invented and applied, as he fays, with fuccefs to fome of his clocks, the principle of which was, that as the ball of the pendulum revolved in an horizontal circle, when fufpended by a vertical axis, the centrifugal force and power of gravity fo counteracted each other, as to produce an equable motion, while the arbor revolved without an efcapement. We are not informed why this pendulum has not been imitated.

The next invention worthy of notice in clock-work, was the mechanifm of *repetition*, by means of which the clock is made to obey the pull of a perfon in bed, who, from any caufe, may wifh to know the hour which was laft ftruck; this ingenious contrivance, in a great meafure, has fuperfeded the ufe of the ftriking-work with the count-wheel, and was the invention of Barlow, a London clock-maker, about the latter end of the reign of Charles II. *viz.* in the year 1676.

The noife which this curious piece of mechanifm made in the world, fet feveral ingenious artifts to making repeating apparatus, paricularly Quare, in London, and Julien Le Roy, Collier, Larçay, and Thiout, on the Continent (Machines approuveés, tomes v. and vi.). Nearly about the fame period, we find that the comparifon of the earth's rotation with the regular motion of a pendulum clock, produced a defire to indicate not only *mean* but *equated* time on the dial-plate, by various contrivances, which, by the bye, were by no means calculated to improve the regularity of the going part, but only added to the complexity of the machine, and introduced unneceffary and variable friction. We know not certainly who was the firft to execute the equation work, but, according to Sully, an Englifh clock-maker, who fettled at Paris (Regle artificielle du Temps, ed. 1717), the firft equation clock which is recorded, was fent from London to Charles II. king of Spain, before 1699. This contrivance, which was more curious than ufeful, caufed a great number of attempts to produce the fame effect; father Alexander, a Benedictine, prefented a project of this kind to the Academy of Sciences at Paris, in 1698: Le Bon, a Parifian clock-maker, prefented another, which was much admired, to the fame fociety, in 1717; which was alfo done by Julien Le Roy, in the fame year, at Paris; and to thefe names we may add thofe of Thiout, a curate of St. Cyr, Duchefne, Kriegfeiffen, Enderlin, L'Admiraud, Paffemant, Rivaz, Berthoud, and others, who have beftowed much time on a fubject which requires only the infpection of an equation table, and which, therefore, our Englifh artifts now think an expenfive trifle, fcarcely worth their notice, any further than as a matter of curiofity.

The equation mechanifm naturally led to the practice of making clocks to go a month, three months, and even a year, with one winding up; likewife to the introduction of mechanifm to fhow the fun and moon's rifing, culminating, and fetting, and planetary motions in general. Indeed Oronce Finée, mathematician to the French kings, Francis I. and Henry II., had made a planetary clock fo early as 1553, concerning which, and the theory of the planetary motions, he publifhed a Treatife, at Paris, in 1557; and the automaton of Huygens, made in 1703, was properly a planetary clock, and one of a very ingenious conftruction.

We come next to an important improvement, which, like moft other real improvements in the art of meafuring time accurately, belongs to the Englifh, we mean the introduction of the anchor pallets, which, even Berthoud confeffes, was a contrivance of Clement, a London clock-maker, in the year 1680 (fee Smith's Horological Difquifitions, London, 1698); the advantage of this efcapement, with an horizonal arbor for the fwing-wheel, as it is called, over that of the crown-wheel efcapement, is, that it will admit the efcape to take place with a fmall angle of vibration, fo as to prevent the maintaining power from acting on the pallets a long time by a direct pufh; as was the cafe with the crown-wheel efcapement; befides, a fhort arc of vibration in a circle is so like a cycloid at the lowest point, that a short arc, with a heavy ball on the pendulum, soon began to be adopted generally, to the exclusion of the cycloidal cheeks, which, had they possessed their theoretic property in practice, would now have been of little value with a vibration in short arcs, even if the suspension thread had been strong enough to bear a heavy weight, and at the same time sufficiently flexible. This change in the clock escapement introduced the custom of suspending the pendulum from a cock, by means of a piece of watch spring, which was another important invention of Clement, according to Smith's authority. It may be proper to observe here, that the truly ingenious Dr. Hooke too claimed the reputation of being the inventor of the anchor escapement, and affirmed, says Sully, that he had shown to the Royal Society a pendulum with a similar escapement, soon after the fire of London, in the year 1666, as we have seen, when we treated of *Chronometers*, that he also contested with Huygens and Hantefeuille the honour of having been the inventor of the balance-spring of watches.

But whether Clement or Hooke were the inventor of the anchor escapement, it was soon found that a clock of this construction gained time considerably by an addition to the maintaining power, or, which may be considered as the same thing, by diminishing the weight of the pendulum ball, the cause of which is the recoil, or retrograde motion, occasioned in the swing wheel, which, opposing the natural vibration, shortened the arc in the ascent; the seconds pendulum, with this escapement, was called for the first time, the royal pendulum.

Such was the state of clock mechanism, and such were the alterations and improvements therein, at the conclusion of the seventeenth century, or beginning of the eighteenth, which period constitutes a fourth epoch in the history of clock-making. The expansion of metals by heat had been known ever since the year 1648, but the ingenuity of art had not yet devised a remedy for the alternate elongation and contraction of the pendulum rod in summer and winter respectively, though the use of the clock in astronomy imperiously demanded some compensation: this honour fell to the lot of our celebrated George Graham, who, in the year 1715, succeeded in his attempt to preserve the distance from the point of suspension to the centre of oscillation of a pendulum unaltered, notwithstanding it was exposed to all the variations of temperature incident to our climate; the compensation was produced, as will be more particularly described under the word PENDULUM, by means of mercury enclosed in a cylindrical glass vessel, guarded by a frame, and substituted for the ball of a metallic pendulum rod, so that while the rod of metal, constituting the verge of the pendulum, lengthened downwards, the column of mercury lengthened upwards, which was an original and truly ingenious idea. Pendulums of this construction, when well adjusted, have been found to measure time with a degree of accuracy far beyond what the former pendulum had any pretensions to, for a continued length of time: the principal objection to its general adoption was its liability to break in carriage, or by other accident:—but Graham, feeling the force of this objection, took a wide view of the subject, and, looking round for other resources, suggested the idea of using the opposite expansions of different metals as a means of compensation in a pendulum, which idea was immediately adopted by Harrison, at that time an obscure carpenter in Lincolnshire, at a village called Barton; who, overcoming all the difficulties attending his retired situation, which is the property of a great genius, astonished the world by the production of the grid-iron pendulum; a pendulum which is not liable to the objection of want of portability, and which has till lately been generally adopted in astronomical clocks of the best construction. For its description we must again refer to the article PENDULUM. Still, however, a better escapement than the common anchor escapement was wanting; for it was not sufficient to have obtained an invariable pendulum in point of effective length, while its natural isochronal property, arising from gravity alone, continued to be greatly disturbed; *viz.* while alternate additions and subtractions of force were derived, and that often unequally, through the medium of the train of wheel-work to the escapement, from the maintaining power first, and thence improperly modified to the pendulum itself. Accordingly, we find Graham, about this time, becoming the inventor of the dead-beat escapement, and also Harrison of a silent escapement, which will go without oil; both of which are specimens of great originality of contrivance, as will be seen when we come to describe them in their proper place: the former of them has proved itself of such great utility, that it has been adopted in the generallity of regulators or clocks for astronomical observations, in conjunction with Harrison's grid-iron pendulum, moving with a heavy ball in a small arc of vibration: of this kind is the clock at the Royal Observatory, at Greenwich, of the accuracy of which it has been affirmed, that it seldom gains or loses, on an average, more than one second of time in five days. To avoid the wearing out of the parts most in action, and the influence of friction, the best clocks of this construction, like the one we have just mentioned, have pallet wheels of hardened and polished steel with pallets of ruby or agate, which require little or no oil: this kind of substance, we believe, was first used in time-pieces by a Frenchman, De Baufre, about the year 1704. The pivot holes also are sometimes bushed with jewels, to avoid the production of verdigris, and the clamminess of thickening oil; but the consequent additional expence seems to be hardly compensated by such a refinement as the last.

Harrison was also, as we have seen before, the inventor of the auxiliary spring and additional ratchet on the barrel arbor, which is a much neater way of making the clock go during winding, than that of Huygens by means of an endless chain, or of the forcing elastic bolt, which has been made to slip into a tooth of one of the wheels, and to push it forwards during the act of winding and for some minutes after.

We might now suppose that the clock has arrived at its *ne plus ultra*, with respect to further improvements, but still we find so many successive alterations, if not improvements, in the escapement, and mode of compensating the pendulum's expansion, that to notice all the fanciful minutiæ that have been magnified into importance by different modern artists, would be to write a long volume on the subject. We will, however, out of the great variety of horological contrivances in this century, select those which have originality and utility to recommend them to public notice, and pass in silence, for the present, over the inventions of chimes, organs, cuckows, planetary motions, atmospherical winding-up, mercurial mover, &c. &c. as objects of fancy more than of real use in clock-work. (For the two last see "Machines Approvées.") Among the contrivers of detached and other clock *escapements*, as will hereafter be seen under this word, we may place Grignon, Mudge, Cummins, Nicholson, &c. in London; and on the Continent Julien le Roy, Peter le Roy, Sully, Du Tertre, De Bethune, Le Paute, Amant, Robin, Berthoud, &c. all of whom have merited commendation for ingenious contrivances in their construction of this most scientific part of the clock. The principal inventors of compensation pendulums, (which will be described under the

the word PENDULUM,) after Graham and Harrison, have been, in France, Regnauld, Deparcieux, Julien le Roy, Cassini, and Berthoud; and in England, Ellicot, Cummins, Nicholson, and Troughton, the last of whom has very recently made such a disposition of the grid-iron pendulum, by means of concentric tubes of brass containing within them the rods of iron, as gives it the appearance of an ordinary simple pendulum rod; and his accurate mode of adjusting for temperature by a delicate spirit-level pyrometer, lately invented, bids fair for introducing this elegant pendulum into general use in clocks which profess to be accurate; indeed, we know, that many pendulums of this construction have already been made for observatories both public and private.

We might mention here various curious as well as useful engines, tools, pyrometrical, and other instruments, which owe their origin to the successive improvements in clock-work, but we think the subject of sufficient importance to demand a separate account of these. We must not, however, pass in silence over some other real improvements connected with the pendulum, one of which is, fixing the ball at the centre of oscillation, instead of supporting it by a tapped nut at the lower extremity, the latter of which methods is only useful when a simple substance, such as metal, wood, glass, &c. is used for a rod; for in these cases a species of compensation is effected by the upward expansion of the ball; in some of which cases a pin, passing through a point of the ball between the centre and lower extremity, will be still better. In those constructions where the ball itself is not easily adjustable, a second light ball is made to screw up and down a projecting piece of the rod below the heavy ball, to adjust for time, and sometimes a micrometer-screw is adapted for measuring the quantity of the adjustment; this is an idea, no doubt, borrowed from Huygens, whose clock had a second adjustable weight on the body of the rod to answer the same purpose, which circumstance we omitted to mention before. The improved suspensions, however, have rendered these secondary balls in many clocks superfluous, which requiring the clock to be stopped for their adjustment were inconvenient; in these suspensions the adjustment for rate is made by a micrometer-screw at the cock or top of the pendulum, even while going, to which mechanism also is added a lateral adjustment for putting the pendulum into beat, instead of bending the fork as is practised in ordinary clocks. Lastly, the modern practice of fixing the cock to the solid wall or other steady situation, and allowing the pendulum to find its own perpendicular line before it be fixed in that situation, is among the real improvements of this art, and cannot be too much recommended. But, notwithstanding all these, and doubtless other improvements in the art of clock-making, one desideratum yet remains to be discovered; *viz.* a simple substance that is *not expansible* by heat, for the rod of the pendulum; we think that pyrometrical experiments, on different substances of nature and combinations of art, have not yet been sufficiently extended, and we beg leave to suggest an opinion, for which we are indebted to Mr. Troughton, that tobacco-pipe-clay, or the composition of Wedgewood's thermometer, if properly baked, may prove on trial to afford a very simple rod, at least for a half-seconds pendulum; particularly if a metallic cap, cemented or otherwise fastened to its upper extremity, should be furnished with a knife-edge suspension, which the celebrated Berthoud, as we have said, affirms has less friction than the slip of watch spring; but if the latter be preferred, we presume the compensation for it, and also for the argillaceous rod, if it should require any, may be made by pinning the ball a little below the centre to the lower extremity of the rod, and then the adjustment for time may be as usual at the cock, with lateral screws to close the slit when the adjustment is complete. From the experiments which we have made with wooden pendulums, we find that they are more affected by moisture than by heat, and are therefore not to be depended on.

Turret Clock of the Royal Palace at Hampton Court.

After having given a history of the principal improvements made from time to time in clock-work, we propose to describe, individually, so many clocks of different constructions, in successive order, as will enable the reader to form a competent judgment of their properties and relative merits, which office we undertake with the more pleasure when we reflect that the English language is yet without a book descriptive of the various constructions of a machine, which, in one form or other, is now in the possession of almost every house keeper.

According to Dr. Derham, the oldest English clock extant is in a turret of the royal palace at Hampton, constructed in the year 1540, which time was in the reign of king Henry VIII. by a maker whose initials are N. O. When we consider that this clock contains mechanism for representing the motions of some of the heavenly bodies, and that the celebrated Copernicus was living at the time of its date, and had not published his book "On the Revolutions of the Celestial Orbs;" when we reflect also, that more than a century elapsed after this time before the pendulum was applied as the regulator of clocks, these considerations appear sufficiently interesting, to induce a minute examination of the wheel-work of this ancient clock, particularly of that part of it which constitutes its celestial mechanism.

Fig. 1, of *Plate* X. is the calliper of the wheel-work which produces the celestial motions, taken from Dr. Derham's "Artificial Clock-maker," published in 1714 (third edition), whose account we will first copy in his own words, and then make some observations on the value of the wheel-work. The Hampton Court clock, says the Doctor, "shews the time of the day, and the motion of the sun and moon, through all the degrees of the zodiac, together with the matters depending thereon, as the day of the month, the sun's and moon's places in the zodiac, moon's southing," &c.

"To shew how completely (for that age) the wheel-work is laid under the moving part of the dial-plate, I have given the calliper thereof, which represents the several wheels and pinions only which lie under the dial-plate, and drive the several motions in this manner. In the centre of all, both the dial-plate and its wheel-work are placed on a fixed arbor, which hath a pinion on the end of it, which drives both the solar and lunar motions, by means of a large wheel of 288 teeth turning round upon it once in 24 hours, which large wheel is drawn round by a pinion of 12, fixed on the arbor of the great wheel within the clock, which turneth round once in an hour. The wheel 288 thus turning round in 24 hours, carries about with it the wheel 37, and its pinion of 7 leaves, as also the other prickt (dotted) wheel, and its pinion, on the other side. The pinion 7, of the wheel 37, drives another wheel of 45 teeth, which carries round the moon's ring or circle. On the opposite side the aforesaid pinion 8 drives round the prickt wheel, whose pinion drives a wheel of 29 teeth, whose pinion, of 12 leaves, drives round the wheel 132 that carries the sun and the zodiacal matters."

"These were the numbers of the wheel-work (continues the Doctor) remaining in the year 1711; but the prickt wheel and pinion were taken out formerly by some ignorant workman that was not able otherwise to amend the clock; but

but were supplied, and the whole movement repaired lately, by that skilful artist, Mr. Lang. Bradley, in Fenchurch Street, London." (p. 121, 122.)

This description gives a clear idea how the movements were actuated; but the numbers of the dotted wheel and pinion being unknown, leave the solar movement incomplete, thus $\frac{*}{8} \times \frac{29}{*} \times \frac{132}{12}$, so that the exact value of this original combination of wheels and pinions for the annual motion unfortunately cannot be with certainty known; though there is no difficulty in ascertaining a wheel and pinion to be substituted, to complete the wheel-work for either a solar or a civil year.

The wheel-work for a lunation, however, is entire, namely, $\frac{37}{8} \times \frac{45}{7}$ or $\frac{1665}{56}$ of 24 hours, which will be found to be equal to $29^d\ 17^h\ 34^m\ 17^s.14$, which is too long a period by $4^h\ 50^m\ 14^s.31$. This excess, in the short space of one lunation, it will be remarked, is very considerable; and it will be inferred from hence, either that a synodical revolution of the moon was not at that time well ascertained in England, or that the inventor of the astronomical movement was unable to calculate numbers more accurate to represent it by wheel-work. We are of opinion, notwithstanding, that neither of these was the case, and our reason for such an opinion is founded in these three considerations; first, great ingenuity is shewn in the disposition of the wheel-work, so great indeed, that it will be seen hereafter, that Mr. Ferguson has evidently copied it in the dial-work of his principal astronomical clock; secondly, the calculations have evidently been made for a lunar day, and not for a lunation, because the moon's age is indicated by the difference between the solar and lunar apparent daily motions, that is, by the solar hand pointing to the moveable lunar dial-plate, and not by a lunar index pointing to a graduated fixed plate; and, thirdly, the length of the lunar day was not ascertained with accuracy by any means so remotely as a lunation, on account of a deception that existed in the determination. Let us examine these considerations a little more closely; as the large wheel of 288, which revolves in the space of 24 hours, carries both the solar and lunar movements along with it, except the pinion of 8, which remains always immoveable in the centre, it follows, that, because this great wheel revolves from west to east, the wheel of 37 borne by it, and connected with the fixed pinion, will revolve in the same direction the space of 8 teeth out of 37 in every 24 hours; also the pinion of 7, fixed on the centre of the wheel 37, will, by the same connection, be carried $\frac{8}{37}$ of 7 teeth in the same time, but the second wheel of 45 will revolve in a contrary direction, or from east to west in each 24 hours, the space $\frac{8}{37}$ of $\frac{7}{45}$ parts of a solar day, which, reduced into a simple fraction, is $\frac{56}{1665}$ of 24 hours, or 48.432432, &c. minutes, so that the falling back of the wheel of 45 in every revolution of the large wheel occasions the moon's daily space on the dial-plate to be equal to 48.432432 minutes on the contiguous solar face of 24 hours, and, if we divide the whole of 24 hours, or 1440 minutes, by this quantity, we shall have $\frac{1440}{48.432432} = 29^d\ 17^h\ 34^m\ 17^s.14$ for the lunation, as before.

In order now to see how large the day's space for the moon's age ought to be on the moon's plate, we must divide 1440, the minutes in a day, by 29.53058, the days in a lunation, and the quotient 48.76301 will be the number of the minutes that the moon's plate ought to lose, with respect to the solar index, in a natural day, which quantity differs from what the wheel-work effected only .33057, or very nearly ⅓d of a minute's motion in every 24 hours, which would be deemed very inconsiderable at a time when the clock itself must have been without such a regulator as would make it go truly for any length of time; the inventor, therefore might not think it necessary to calculate a more accurate movement.

But there might be another cause of error in the calculation arising from the assumed data; it appears, as we have intimated, that for a considerable time after the period in question, though the length of a lunation was known pretty accurately, yet the length of an exact lunar day was not properly apprehended; even Benjamin Martin among other astronomical writers (Institution of Clock-work, vol. ii. p. 412.), who had lunar tables before him, has inconsiderately but erroneously asserted, that the moon passes the meridian on each day at a mean rate about $48\frac{7}{10}$ minutes later than on the preceding day; it is true, indeed, that the difference between the sun's and moon's daily mean motions in the ecliptic is $12°\ 11'\ 27''$, which space answers very nearly to $48\frac{3}{4}$ of time, but then, as we have already seen, this is the distance between these two heavenly bodies at the end of a solar day after new moon, and not at the instant when the moon transits the meridian the first time after, as has been falsely concluded; for during the time that the earth is revolving on its axis the space of $12°\ 11'\ 27''$ or $48\frac{3}{4}$ minutes of time, the moon continues her advance from the sun, and gets as much farther as corresponds to 1.643 minutes more; and lastly another small advance is made whilst the earth is revolving this last space; and so on till the moon is found on the meridian: the aggregate of the moon's daily advance from the sun and of all the successive proportional parts may be thus ascertained at one operation; because a synodical revolution of the moon is performed in 29.53058 days, and because the moon passes the meridian less frequently by once than the sun does in that time, let 1440 be divided by 28.53058, and the result will give the lunar day equal $50^m.472$ or 50 minutes and 28.32 seconds. Mr. Ferguson, however, has discriminated between a lunar day, and the time answering to the moon's daily motion added to a solar day, one being a corrected and the other an incorrect period; in consequence of which we find the annexed note in page 116 of his "Tables and Tracts," *viz.* "It is generally believed that the moon revolves from the meridian to the meridian again in 24 hours 48 minutes, but that is a mistake: for if she did, there would be 30 complete days from change to change."

We repeat, therefore, that a misapprehension of this nature was very likely to be productive of an error in the calculation of a movement which was intended to represent the moon's meridian passages: and let it be recollected, that what has been here said respecting the two lunar periods $48^m.76301$, and $50^m.472$, will be serviceable in ascertaining the moon's age and the tides at any place; the former, being the moon's daily motion in solar time, applies to calculations of the moon's age; and the latter, being the exact length of a lunar day, applies to the ascertaining of the tides, which distinction, we think, is not generally made.

After the writer of the present article had made the preceding calculations and observations on the original construction of the astronomical clock at Hampton Court, he felt an inclination to inspect the present clock, that he might know what the solar movement is, which Bradley is said to have substituted, when a wheel and pinion of the original movement were lost; accordingly, on the 8th of May 1802 he embraced an opportunity which occurred, of gaining permission to ascend to the lofty situation in which this clock is placed, which enterprize was attended with some personal danger; but it proved on a minute and careful examination, that the whole of both the annual and lunar movements are different from the original ones recorded by Dr. Derham.

The lunar movement is $\frac{59}{10}+\frac{45}{9}=29\frac{1}{2}$ days and the annual one $\frac{73}{12}+\frac{42}{7}+\frac{150}{15}=365$ exactly. The prefent central pinion is a double one confifting of a 10 and a 12, fixed as the former one of 8 is defcribed to have been, and pinned together; they are made of box, as are alfo the pinions of 7 and 9, to prevent their cankering, or oxiding, as it is now called, and both the trains are arranged as already defcribed. The wheel of 42 is made of brafs: but the reft, being very large, are made of iron. The great wheel of 288, which connects the clock-work with the aftronomical movements, appears to be the only portion of the original work, both by its marks of antiquity and the number of its teeth, which are cut on the inner edge of its circular part; there are two crofs bars riveted to this indented rim to carry the heavenly movements, and as there is no counterpoife to thefe, it was fufpected at the time that their rifing and falling weight would alternately accelerate and retard the going of the clock, which is connected with it by means of an horizontal arbor about 3 yards long by eftimation: accordingly, on inquiry, it turned out that the time of the day indicated is fometimes 5 minutes or more too back, and again as much too forward on the fame day, every day, which circumftance had not before been accounted for. Indeed our author had made a memorandum, before he faw this clock, merely from confidering its conftruction in Dr. Derham's account, that moft probably this would be the cafe, unlefs there fhould be fome counterpoife.

The infcription " L. Bradly, 1711," was marked on the frame of the going part of the clock, which has evidently been new, either all of it at that time, or fome part of it fince, fo that what the original regulator was, does not appear, nor are the initials " N. O." to be found at prefent. There are three barrels and weights, one for the going part which has a very heavy long pendulum; one for the ftriking part; and one for ftriking the quarters: the prefent efcapement is a pair of pallets acting alternately into pins projecting from the plane of a wheel with an horizontal arbor, which kind is now pretty common in England, and, according to Berthoud, was invented by M. Amant, a clock-maker of Paris, late in the eighteenth century. (See ESCAPEMENT.)

In Grofe's Antiquities it is faid that this clock, confidered as an aftronomical clock, was invented by Tompion; but this account cannot be true, becaufe that famous artift lived in Dr. Derham's time, a century and half after the original conftruction; he may in all probability have been employed in making fome of the alterations either in the aftronomical or going part, which circumftance has given rife to this account.

The hand and divided circles are in the following order on the face, *viz.*

1. or inmoft fmall circle—twice XII for ☾'s fouthing:
2. Moon's age $29\frac{1}{2}$:
3. Ecliptic with figns and days of the month:
4. Sun and hour hand revolving in 24 hours:
5. 24 hours marked I. II. &c.

The moon's phafe is fhewn by a circular hole cut on the hour index covering more or lefs of a blackened plate placed under it on the lunar dial.

The going and ftriking parts of the clock before us have nothing particular in them to require our further notice.

A Thirty-hours Clock, with a 'Larum and Count-wheel ftriking Work.

An ordinary 30-hours houfehold clock has ufually a feconds pendulum, 39.14 inches long, in the latitude of London, as meafured from the point of fufpenfion to the centre of ofcillation, according to a mean of five determinations, and is contained in a cafe of wood of correfponding length refting on the floor of the room where it is placed; its going and ftriking parts are actuated by two feparate ponderous bodies, the cords or chains of which go refpectively round two diftinct pullies, with pins inferted into their grooves, to hold the cords or chains from flipping in a detached ftate, without taking the pullies along with them; and in the act of winding up every morning, or every evening, as may be the cuftom, each ponderous body, ufed for actuating the wheel work, is drawn up feparately and fucceffively; the ftriking mechanifm in moft of the modern clocks is of the kind defcribed hereafter and feen in *Plate* XII. known by the name of the rack and fnail ftriking part; but as the older clocks and fome few of the modern ones are made with the count-wheel ftriking mechanifm, we propofe to defcribe, in the firft place, a clock with ftriking mechanifm of this kind in its moft improved ftate, together with an alarum, or 'larum, for roufing a perfon from fleep at a given hour, and alfo a fimple method of making the clock go while it is under winding. *Plate* IX. of *Horology* fhows a perfpective view of a clock of this kind in *fig.* 1, where the covering parts are removed, fo as to allow an exhibition of all the parts of the mechanifm in their refpective fituations, which, we believe, has never been properly done before. The frame of this clock is nearly a cube made of fix plates of brafs, with four pillars at the corners connecting the top and bottom plates, and the bell is mounted over the frame, as reprefented in the figure; there are befides, within the frame, two pair of crofs bars of brafs, one pair holding the going part, and the other holding, feparately from the going part, the ftriking part of the mechanifm; all which are too plainly feen to require particular reference to the drawing. In a common 30-hours clock that indicates feconds, the centre wheel arbor ufually carries the minute hand, and revolves in an hour, and with pinions of 8 this wheel has 64 teeth, and the fecond wheel 60, with a fwing wheel of 30; but with pinions of 6 the centre wheel has 48 teeth, and the fecond wheel only 45, with a fimilar fwing wheel for the common anchor pallets; but the clock before us does not fhew feconds, and confequently has higher numbers in its train, and a pendulum fhorter than a feconds pendulum: the firft wheel, *a*, on which the pulley for winding up the going part is fixed faft without a ratchet in this conftruction, for a reafon to be explained by and bye, is affumed as revolving in two hours in order that the fall of the fufpended weight may not be fo great as it would have been if it had revolved once in an hour; this firft wheel of the train has 80 teeth, and drives the pinion of 8 on the arbor of the fecond wheel, *b*, which has alfo 80 teeth, impelling a fecond pinion of 8 on the arbor of the fwing wheel, *c*, which has 45 teeth; the fwing wheel therefore makes 100 revolutions $\left(\frac{80}{8}\times\frac{80}{8}\right)$ while the firft wheel revolves once; *i. e.* it revolves once in 50 minutes, and therefore is not proper for carrying a feconds hand; but the 45 teeth of the fwing wheel do not all completely efcape the pallets of the anchor

anchor in less than 90 (45 × 2) vibrations of the pendulum; hence 50 × 90 = 4500 are the vibrations per hour, and as the lengths of all pendulums are inversely to each other as the squares of their vibrations per hour, the pendulum before us must necessarily be 20 inches long, for as the square of 4500 : the square of 3600 :: $39^{in.}14 : 20^{in.}$, very nearly. The pallets are of the recoil kind (see ESCAPEMENT), and have an arbor of great length, with a crank in the middle of it nearly, to avoid the fly of the striking part which comes through an aperture in the top plate; the inner end of the pallets arbor has its pivot inserted into a piece of metal, *d*, on the top plate, and the outer end of the same has its pivot passing through a cock, *e*, on the same plate, which cock also bears the pendulum by a slip of watch main-spring; the pendulum receives its impulse from the crutch, not seen, attached to the protruding portion of the said pivot. What we have so far described constitutes what is called the going part, sometimes also called the watch part of the clock, from its watching the lapse of time. The first wheel, *a*, which revolves once in two hours, is not placed in the centre, but a little below, and has its strong arbor passing through the cross partition bar, *ff*, of the interior frame work, and receiving a wheel of 40 teeth, and also a pinion, *h*, of ten leaves, which are attached together and inserted on this arbor by friction; the wheel of 40, which, we have seen, revolves in two hours, drives a concealed pinion with a long tube, called the cannon pinion, the place and size of which are ascertained by dots at *k*; on the tube of this pinion, which has 20 teeth, and which therefore revolves in an hour, is placed the minute hand, *n*, the end of the tube being squared to admit the square aperture of the hand; the pinion of ten leaves, which also revolves in two hours, drives the wheel, *i*, of 60 teeth in twelve hours, the tube of which admits on its circular part the hour hand, *m*, which consequently revolves in 12 hours $\left(2 \times \frac{60}{10}\right)$; this work is denominated the dial-work, being that which regulates the relative velocities of the two hands as seen in *fig.* 3. The next portion that offers itself for description is the 'larum portion, which has an immediate connection with the dial-work, and has the time of its going off limited thereby. On the tube of the 12-hours wheel, *i*, is placed loose, or at least so tight only as friction will fix it, the small plate, *o*, pointed to by the tail of the hour hand, *m*, which small plate has 12 hours engraven on it, and a pin inserted into it behind, which comes in the way of the lever *p* every 12 hours; this pin is put into a certain situation with respect to the hour of 12, and the end of the lever, *p*, also, in order that the pin may catch the said lever at a certain hour placed under the tail of the hour hand at any time previously to the hour intended; the consequence is, that when the 12-hour wheel has revolved far enough to present the pin of the small 'larum dial borne by it to the end of the lever *p*, this lever is elevated a little, and as its arbor, *q*, has its pivots running in the interior frame work of the going part, a second lever, *r*, on the same common arbor, is also at the same time elevated from the pin, *t*, of an escapement crown wheel, *s*, better seen detached in *fig.* 2, at which instant the small weight of the 'larum pulls the pulley on the back of the escapement wheel, *s*, of the 'larum, and gives it a rotatory motion as long as the weight continues to fall. The escapement wheel here mentioned has coarse teeth of the serrated kind, which act with two pallets on the perpendicular arbor *v*, in the same way that the pallets of a common watch act, except that the latter are on a horizontal arbor, and have their frequency regulated by the vibrations of the balance; whereas here there is no regulator, but the pallets go and come alternately as fast as the impelling weight can force them to move; on the top of the perpendicular arbor of these pallets is fixed a hammer with two faces within the bell, represented by dots, which moving backward and forward from one interior side of the bell to the other, with the force communicated to the pallets by the pallet-wheel, make a reiterated noise, the intensity and continuance of which are sufficient to disturb the repose of a sound sleeper. When the weight has drawn up all the cord, it is only necessary to pull it up again, and the lever, *r*, acts as a detent with the pin, *t*, of the pallet-wheel, till the pin of the 'larum dial, set to any given hour, shall again detach it, when the same continued noise will be resumed.

The last portion of the clock is the striking portion, which also has a connection with the dial-work; the wheel, *g*, which revolves in the space of two hours, has two pins at the distance of a semicircle from each other, behind the wheel as seen in the figure; one or the other of these two pins at the end of each hour seises the end 1 of a tail piece attached to the long horizontal arbor 2 3, which reaches the whole depth of the two internal frames; this long arbor has another bar 4, or detent, which reaches far enough to fall in the way of a pin in the wheel 7, or warning wheel, so as to arrest the motion of the striking movement when in its quiescent position. Parallel to the long arbor, and above it, is another but shorter arbor 5, turning by its pivots in the interior frame of the striking part; this short arbor 5 has a bent lever 6 by which it may be raised by the contact of the detent 4 of the long arbor 2 3, and also two catches or detents 7 and 8, all fixed at right angles to the axis of motion; the detent 7 falls into a notch made in a hoop placed fast to the wheel marked 13, thence called the hoop-wheel or detent-wheel sometimes, which revolves once at every blow of the hammer, and the second catch 8 falls successively into 12 notches cut at unequal distances on the edge of plate 11, called the locking plate, which is fixed fast to the wheel marked 12, called the count-wheel, because its teeth count the stroke-spaces between the notches of the locking-plate that are placed respectively at $\frac{1}{78}$, $\frac{2}{78}$, $\frac{3}{78}$, &c. of the circumference of the plate from each other, as explained when we described the ancient clock of Henry de Wick. The wheel 9, first actuated by the cord or chain passing round the third pulley fastened to it, has 12 pins for raising the tail-piece 10, of the hammer, the arbor, *l*, of which is seen in the figure; the spring of the hammer tail is concealed from view, but the shaft of the hammer is seen passing through an opening in the top plate at 16, and the head of the hammer is represented within the bell, where it strikes, by a dotted design above 16. The pin-wheel or striking-wheel 9 has 60 teeth, and drives a pinion of 10 leaves on the arbor of the hoop-wheel 13, behind the cross piece of the frame work; the hoop-wheel has 70 teeth driving a pinion of 7 leaves on the remote end of the arbor of the warning wheel 7, of 56 teeth; which wheel again impels the pinion 14, of 7 leaves, on the arbor of the fly, one half of which is seen through an opening in the top plate at 15. On that end of the arbor of the pin-wheel which passes through the back part of the frame-work is inserted a pinion of 12 leaves, called the pinion of report, driving the counting wheel 12 of 78 teeth. The action of the striking part is thus:—

One of the pins in the two-hour wheel, *g*, first lifts the tail 1, of the long lever 2 3, and with it the detent 4, the warning wheel 7 is not yet at liberty, but begins to revolve the instant that this detent has raised the curved arm 6 over it, which arm raises with it both the catches or detents 7 and 8, that leave the hoop-wheel 13, and also the count-wheel 12, under-

12, under the command of the ſuſpended weight; the motion of the wheel 7, however, does not proceed far till its detent 4 is raiſed into the way of its pin, and the motion of it is arreſted; the noiſe of this temporary motion of wheel 7 is called the warning, and the wheel itſelf the warning-wheel; preſently the pin of the 2-hours wheel, *g*, drops from the end of the tail 1 of the arbor 2 3, and this tail as well as detent 4 reſume their quieſcent poſition; during the temporary motion of the warning wheel 7, the hoop-wheel, and alſo the locking-plate attached to the count-wheel, had moved far enough to take the notches from the claws of their reſpective catches or detents 7 and 8, the moment, therefore, that the detent 4 takes its quieſcent poſition, the warning-wheel is again at liberty, as are alſo the hoop-wheel and count-wheel; the whole movement, conſequently, now proceeds, and the pin-wheel raiſes the hammer tail as often as the pins meet with it, until the detent 8 meets with a notch to receive it into the locking-plate, at which inſtant all motion is at an end, and the detent 7 of the hoop falls alſo into its notch, and holds the whole movement firmly in a quieſcent ſtate, till the ſecond pin of wheel *g* again detaches the detents, and renews the ſame proceſs; which happens at the concluſion of every hour.

From this account of the movement of the ſtriking part, and of the other auxiliary parts of this mechaniſm, it is eaſy to apprehend the reaſon of the numbers of teeth fixed upon in their different wheels and pinions; for firſt, becauſe there are 12 pins in the ſtriking or pin wheel, it is neceſſary that the pinion of report on the ſame protruding arbor ſhould have 12 leaves, in order that every tooth of the count-wheel, which counts a ſtroke of the hammer, ſhould have its motion correſponding with that of the pins reſpectively; but in twelve hours there are 78 ſtrokes, therefore 78 teeth in the count-wheel, one of which meaſures the firſt interval on the locking plate; two of which the ſecond; three, the third, and ſo on till the laſt ſpace between the notches is meaſured by twelve teeth of this wheel; again, as the pin-wheel has 60 teeth and twelve pins, each pin is removed from the next $\frac{60}{12} = 5$ teeth; if the hoop-wheel, or detent-wheel were neceſſarily obliged to have an exact revolution at every ſtroke of the hammer, the pinion on its arbor driven by the pin-wheel muſt neceſſarily have five leaves only; but when the teeth are not laid very deep into one another, the play will allow the hoop-wheel to have only one revolution in two ſtrokes, which is the caſe before us, where the pinion has ten leaves; the pin-wheel, however, might very well have had 96 teeth, and the pinion in queſtion 8 leaves, and then there would have been an entire revolution of the hoop-wheel at each ſtroke. We have ſeen that the count-wheel revolves once in 12 hours and that the pin-wheel revolves in $\frac{78}{12}$ of this time, or makes $6\frac{1}{2}$ turns; but if the number of pins had been 13, and the pinion of report alſo 13, the time of a revolution of theſe would have been $\frac{78}{13}$ of 12 hours, or one in two hours, which is the caſe with the great wheel of the going part, and the two movements would, in that caſe, have been more uniform with reſpect to the calculations of continuance. It is of but little importance what the numbers of teeth be in the two remaining pinions and warning wheel, as they only regulate the velocity of the fly, provided the teeth are numerous enough to act without much friction.

As we mean not to introduce any other clock with the count-wheel mechaniſm after the preſent one, it may be proper to notice here, that when this kind of ſtriking work is uſed in an eight-days clock, or other clock of longer continuance than 30 hours, another wheel and pinion, called in ſuch caſe the great wheel and its pinion, muſt be placed on the end of the barrel, or fuſee, accordingly as a weight or ſpring is uſed for the maintaining power; and the number of teeth of this additional wheel will depend partly on the number of leaves of the pinion and partly on the number of coils of the cord or chain on the barrel, or fuſee, as the caſe may be; which never can be difficult to determine when it is known in what time the pin-wheel revolves, and what the continuance of the clock is required to be; for inſtance, if the pin-wheel revolves with 13 pins in two hours, $\frac{72}{12}$ will be the wheel and pinion to make the barrel or fuſee turn once in 12 hours, and 16 turns will be ſufficient for a continuance of eight days.

The manner in which the clock in queſtion may be placed to go well, is ſhown in *fig.* 3, where A is a bracket fixed to a ſolid wall, to hold the frame containing the works, which are here ſuppoſed to be without a caſe; the face or dial requires no explanation after what we have ſaid of the ſmall innermoſt circle or 'larum dial; nor have we any particular remarks to make on the pendulum, or its rod, in this clock, which profeſſes not to meaſure time alike under the variations of atmoſpheric temperature; but the manner in which one ſuſpended weight impels both the going and ſtriking movements, the former even while winding, is ingenious and deſerves attention. Huygens long ago propoſed and indeed actually uſed an endleſs cord with a detached ratchet, ſo applied that one half of the weight continued always to impel the going movement of his clock, and a detached ratchet gathered up the expended portion of the cord once in 24 hours. (See Clock-*work*.) The preſent contrivance is evidently borrowed from his invention, but its application ſerves two diſtinct purpoſes, one half of the weight impels the going part, and the other half the ſtriking part of our preſent clock, in the manner following;—The pulley of the going part we have ſaid is fixed faſt to the arbor of the great wheel and always revolves along with it, but the pulley of the ſtriking part, like the pulley of the 'larum, has a rachet formed of a click taking hold of one of the croſſes of the pin-wheel, ſo that it will move back without this wheel, but not forwards; the cord, which has its ends nicely united, goes over both pullies, firſt over the ſtriking pulley, as Huygens's does over the detached ratchet, and down the loweſt plate of the clock frame; it then paſſes under the running pulley, *a*, which has the weight hung to it, and up again over the going pulley; thirdly, it comes down again through the ring of lead *b*, which is only a dead weight to ſtretch the cord over the pulley of the ſtriking part; and, fourthly, aſcends again over the ſtriking pulley, where the ends meet; the clock is wound up by pulling the cord, *c*, downwards, till the principal weight is raiſed to the bottom of the bracket, while one of the cords of the running pulley continues to act with half of the whole weight on the pulley of the going part the whole time; ſo that this power, when duly drawn up, is not only equivalent to both the movements, but is perpetual, as well as invariable in its intenſity.

Eight-days portable Clock with repeating Mechaniſm.

A portable eight-days clock differs from an ordinary 24-hours clock principally in five reſpects: in the firſt place, it is actuated by a ſpring; ſecondly, it has a ſhorter pendulum; thirdly, it has conſequently a higher train; fourthly, it requires a fuſee; and, laſtly, it has frequently a crown-wheel eſcapement; in ſhort, it may be conſidered as a watch on an enlarged

enlarged fcale, except that it has ufually the ftriking mechanifm, which is introduced in the repeating watches only. In the clock, which we propofe here to defcribe, we have fubftituted the fwing-wheel with an ifochronal efcapement, for the crown-wheel efcapement, which we are of opinion ought to be banifhed from all clocks and watches entirely, as being too much the flave of the maintaining power. It will not be neceffary to render our defcription of the clock before us very long, as we mean to make it the fubject of analyfis under our fubfequent article CLOCK-*movement*.

Plate XI. of *Horology* prefents a perfpective view of a portable eight-days clock, defigned and callipered agreeably to the numbers and directions given in the article juft mentioned, which conftruction we have preferred defcribing here, in order that the reader may there fee our reafons for every part of the mechanifm, if he wifhes for fuch explanation: let it however be underftood, that we by no means hold out the prefent clock as a model for others to follow, but give it as one of the hundred different varieties or more that might be devifed to anfwer the fame purpofe.

Plate XII. exhibits the dial-work and ftriking part, including the repeating mechanifm of the fame clock, which we fhall defcribe in its turn.

Fig. 1, of *Plate* XI. expofes to view the interior face of the back or pillar plate A A A A, and the wheel-work contained within the frame; B, B, B, B, B, are five pillars fcrewed into the back plate, and tapped at their projecting ends to receive five fixing fcrews, when the front plate is put in its place to complete the frame: there are two barrels with main-fprings, C and D, of which C is for the going part, and is clofed with its cap; but D, which is the barrel for the ftriking part, is left open to fhow the coils of the main-fpring contained in it. There are alfo two fufees, E and F, attached to their refpective great wheels; E the fufee of the going part, and F that of the ftriking part. G is the centre or hour wheel of 64 teeth placed partly behind the great wheel of 96, by which its pinion of 8 is actuated; hence the fufee revolves in $\frac{96}{8}$ of an hour, or once in 12 hours, fo that the 16 fpiral grooves, filled by the gut, allow the continuance to be juft eight days. The fecond wheel H, of 60 teeth, has its pinion of eight impelled by the centre wheel, and in its turn impels the pinion of 8 on the arbor of the third wheel of the train, I, which is here alfo the efcapement wheel; the revolutions therefore of the arbor of wheel I are $\frac{64}{8} \times \frac{60}{8} = 60$, while the hour-wheel revolves once; confequently this arbor, which revolves in $\frac{1}{60}$ of an hour, is proper for carrying the feconds-hand round in a minute. The efcapement-wheel has 60 teeth, and the pendulum vibrates twice in every fecond; but one tooth does not efcape the pallets of the anchor K, until two vibrations have been completed; confequently 60 teeth efcape, *i. e.* the efcapement-wheel makes one revolution in 120 vibrations, or in the fpace of one minute: hence the clock before us indicates half-feconds. The fquare ends of the two fufees are oppofite two holes in the clock-face, at each fide of the centre of the circles of indication, (which are too well known to need defcription), but a little below it, and the fame handle fits both fquares: L is a jointed lever fixed to the interior fide of the front plate called the guard-gut, or fimply the guard, the ufe of which is to prevent the chain or gut from doing more than juft fill the fixteen grooves of the fufee in winding; M is a fpring alfo faft to the interior fide of the front plate, which preffes the lever L towards the middle of the fufee, and keeps it there till the chain or gut, meeting with it, drives it back again, in the act of winding, fo far till the claw *o* is prefented to the beak or catch of the end piece N, which then ftops the further motion of the fufee and limits the quantum of chain to be wound up. Thefe pieces L and M conftituting the guard, being attached to the front plate, are taken off with it, when the frame is difmounted, but we have put them into their places in a detached ftate in our figure, to fhow more evidently the nature of their office. O is the arbor of the warning piece, which will be defcribed in its place prefently. The wheels P, Q, and R, with their refpective pinions, conftitute the movement of the ftriking part, and the fanner S regulates the velocity with which they move. The wheel P has eight pins which lift the crofs piece *t*, of the arbor T, eight times in each revolution of the wheel P; thefe elevations of the piece *t* occafion fo many portions of a revolution of the arbor T, which arbor has its pivot projecting to V, behind the frame, and carrying on its fquared projection the hammer V, *fig.* 2; the hammer is confequently raifed every time a pin of wheel P moves the piece *t*; W is a long and ftrong fpring, called the hammer-tail-fpring, attached to the back plate of the frame, and preffing with its upper extremity under the crofs pin, paffing through a hole in the arbor T, near the face of the back plate; fo that when the hammer is raifed at any time, the fpring W urges it back again with a fmart blow, and makes it ftrike the bell behind the frame, which is concealed from the fight in our figure; but left the blow fhould be too ftrong, a counter fpring, U, is fixed to the contiguous pillar, which breaks the violence of the blow, and makes the hammer return fmartly to its place when the blow is made; this fpring, U, alfo ferves as a guard, in cafe a ftroke of the hammer fhould be made when the bell is taken off at any time. The fufee F is provided with a guard fimilar to that of the fufee E; and the vane of the fly or fanner S is kept to the arbor, on which it is placed, by the friction of a preffing fpring, fo that it will go round either with or without the arbor, the latter of which is the cafe only after the ftriking has ceafed, till the momentum of the fly has been annihilated by the refiftance of the air.

Fig. 3, is a portion of the top of the exterior face of the back plate of the frame, conftituting the fufpenfion of the pendulum: *a* is a bridge, or double cock, in which the projecting pivot of the pallet's arbor is fupported; *b* is a fmall cock over this, or may form a part of the fame, the protruding part of which is flit with a faw, to allow the flip of watch main-fpring, *f f*, to pafs; by which the pendulum rod is fufpended; and *c* is a thumb-fcrew to clofe the flit, and clamp the piece of fpring when the true length of the pendulum is afcertained; the upper end of the fpring, *f f*, is borne by the bearing piece *d* above the frame, to which it is ufually made faft by a pin paffing through the piece *d*, and a hole in a piece of brafs pinned to the extreme end of the fpring; the apparatus for raifing and lowering the piece *d* is better feen in *Plate* XII. to which the reader is now defired to turn for the remainder of the defcription; only let him bear in mind that the effective length of the pendulum is meafured from the inferior edge of cock *b*, in *Plate* XI. to the centre of ofcillation of the bob, and that the quantum of this meafure is adjufted by the elevation or depreffion of the piece *d*, while the flit of the ftationary cock *b* is not clofed by the thumb-fcrew *c*; which adjuftment may be made while the clock is going, provided the flit be again clofed by the thumb-fcrew, otherwife the effective length of the pendulum will be meafured from the piece *d*, and will remain the fame whether this piece be raifed or depreffed.

The

The bearing piece *d*, *Plate* XII. is the remote end of a tranſverſe lever, *c d*, moveable like the teleſcopic tube of a tranſit-inſtrument on two pivots, *a b*, of an axis ſupported by two ſmall cocks, *a* and *b*, clearly ſeen in the figure, ſo that when the pivots are ſtrong and without play in their holes, it is evident that the end *d* can have no lateral ſhake, provided the bar *c d* has no ſpring, *i.e.* provided it be ſtrong; alſo when the interior end *c* is fixed with reſpect to elevation, the exterior bearing end muſt be alſo fixed; the contrivance therefore for elevating or depreſſing the end *d* in the body of the clock caſe at any time may be as well applied to the end *c* in the front of the frame; for a depreſſion of one end of the lever *c d* always produces a correſponding elevation of the other, and *vice verſâ*, ſuppoſing the axis exactly in the middle; but when the axis is out of the middle of the lever, an elevation or depreſſion of either end is in proportion to its diſtance from the axis of motion directly. At *e* is a circular plate of braſs, better ſeen detached in *fig.* 4, called the *riſe* and *fall*, with an arbor ſquared at the projecting extremity, oppoſite a perforation on the face or dial of the clock, to receive a key of regulation; this circular plate, which is pivoted into the cock *f* attached to the front plate of the frame, has a ſpiral aperture through which a round pin in the end of the lever, *c d*, paſſes ſo as juſt to go in without ſhake; hence, whenever the plate *e* is turned by the key one entire revolution, the pin of the lever, which paſſes through the ſpiral aperture, aſcends or deſcends from one end of the ſpiral to the other, and at the ſame time depreſſes or raiſes the bearing end, *d*, a proportionable quantity and with it the bob of the pendulum, as may now be eaſily apprehended; the condition, therefore, with reſpect to the regulation, is, that one turn of the plate, *e*, ſhall effect as great a change in the length of the pendulum, as ſhall be requiſite to bring the clock to a true rate, or keep it ſo when adjuſted, where the pendulum has a compenſation for temperature, or is made of a ſubſtance that alters its dimenſions but little with the variations of temperature of the atmoſphere. In ordinary clocks of this conſtruction, with a ſimple metallic rod for the pendulum, the ſlit may be ſo nearly cloſed at all times as juſt to allow the thin ſpring of ſuſpenſion to paſs, in which caſe the frequent adjuſtments for rate may be made without opening the caſe; but when the pendulum is of any of the beſt compenſating kinds, it will be better to cloſe the ſlit by the thumb ſcrew *c* in *Plate* XI. after the adjuſtment for rate is completed.

Thoſe parts of *Plate* XI. which are viſible in *Plate* XII. are marked with the ſame letters over again, and therefore need not be again deſcribed, but will be of ſervice to elucidate the relative poſitions of thoſe parts, now that the frame is exhibited as mounted. We will begin our deſcription of the ſtriking and repeating work, with the arbor of the centre wheel, G, the end of which is ſeen within at the projecting end of the ſquared part of the tube, or cannon, of the pinion ſeen in *fig.* 2, called the cannon pinion; the tube of this pinion is put tight on the arbor of the hour wheel, which we have alſo named the centre wheel, and has a ſpring placed on the hour wheel arbor, preſſing its poſterior ſurface ſo as to force it forwards againſt the croſs-pin that keeps the hands on; this action of the ſpring occaſions ſo much friction, that though the tube is carried round by the hour arbor, yet it is capable of being moved round, by its hand placed on the ſquare end, independently of this arbor, for the purpoſe of ſetting the hand to the requiſite minute in the divided circle of 60 ſpaces, uſually figured with the Arabic characters: the cannon pinion, as it is called, has 40 teeth, and impels a ſimilar pinion, *g*, round alſo in an hour; this pinion, *g*, which is called the pinion of report, has a pinion of 6 on its arbor, and is pivoted into the cock, *h*, ſo that the ſmall pinion of 6 alſo revolves in an hour; this pinion of 6 again impels the wheel *i* of 72 teeth in $\frac{72}{6}$ of an hour, *i.e.* in 12 hours; this 12-hour wheel has alſo a tube, ſurrounding the tube of the cannon pinion, but in ſuch a way, that a third tube, attached to the bridge, *k*, and ſeen in a detached ſtate in *fig.* 5, is interpoſed between the ſaid two tubes of the cannon pinion and 12 hour wheel; the uſe of which third fixed tube, is to prevent the friction that would neceſſarily take place, if the two revolving tubes had been in contact, and had preſſed on one another, while their velocities are to each other as 12 to 1: on the exterior tube of the 12-hour wheel, the hour hand is inſerted, which indicates the hour among the Roman figures; and it is obvious that whenever the minute hand carries the cannon pinion round, the pinion of report, *g*, alſo moves the ſame quantity, and by means of the ſmall pinion of 6, the wheel *i* at the ſame time muſt move $\frac{1}{12}$ of the ſame ſpace, and conſequently the two hands are ſo connected, that one cannot move without the other, ſuppoſing them both to be faſt to their reſpective tubes; but the hour hand is put on the round part of its tube, and kept to it by mere friction, and therefore may be put to any hour without carrying the minute hand round many revolutions; and yet when once placed right, it preſerves its relative velocity, as though it were more firmly attached to its tube. I is the arbor of the ſeconds-hand, which we have ſeen revolves in a minute, and which meaſures the 120th part in its divided ſmall circle, on the face of the clock, at ſo many vibrations of the pendulum, or at ſo many half-ſeconds. To the 12-hour wheel, *i*, is pinned faſt an indented ſpiral piece of metal, called the ſnail, the ſhell of which it reſembles in ſome meaſure, which ſnail conſequently revolves likewiſe in 12 hours; the indentations appear to the eye to be irregular, as to their relative extents, but each ſubtends an angle of $30° \left(\frac{360°}{12}\right)$ ſo that one indentation, whether near to the centre of motion, or remote from it, is exactly the meaſure of an hour's motion of the 12-hour wheel. The ſteel piece, *m n*, is called a rack from the teeth on the croſs-piece, *m*, the lower croſs-piece of which is called the rack-tail; this rack is moveable on a pin or ſtud at the lower angular point, near which the horſe-ſhoe ſpring, *o*, called the rack-tail-ſpring, preſſes to keep a pin on the remote end of this tail, againſt that indentation of the ſnail, which happens to be contiguous to it; this pin is hid from the ſight, but the place may be ſeen on the extremity of the tail where it is inſerted. On the lever between *m* and *n*, is a bend to prevent its touching the winding arbor F of the fuſee, belonging to the ſtriking part; alſo at *m* is a ſtrong ſteel pin, projecting from the rack. Above the rack is a horizontal ſteel bar, *p q r*, moveable round a ſtud at *r*, which is called the hawk's-bill, from the bill or angular piece at *q*, that catches the teeth of the rack. The piece *s* is fixed to the protruding pivot of wheel Q, *Plate* XI. near its lower extremity, and revolving with it gathers up a tooth of the rack at each revolution, on which account it is called the *gathering pallet*, the catch of the hawk's bill having a contrary ſlope, gives way in the mean time, and comes back again by its own gravity. The pinion of the pin-wheel, P, which has 64 teeth and eight pins, has eight leaves, and therefore revolves once every time that the hammer of the bell is lifted; but we have ſaid that its gathering pallet takes up a tooth of the rack at each revolution of its arbor, conſequently a tooth of the rack is gathered up at every ſtroke of the hammer, when the ſtriking part is in motion. The angular piece, *t u v*, moveable round an arbor, denoted by O, in *Plate* XI. is called the *warning-piece*; its lower end, *v*, falls in the way of a pin in the ſmall hour-wheel, *g*, and its bent end, *t*, paſſes through an aperture, *w*, in the front plate of the frame, and is preſented to the pin in one of the croſſes of the wheel R, of the ſtriking movement within the plate, ſo as to reſtrain the motion of this movement when in its quieſcent ſituation. The action of the different parts may be thus explained; whenever the hawk's-bill, *q*, is lifted from the teeth of the rack, the ſpring, *o*, preſſing againſt a pin near its tail, makes it fall back till it meets with ſome obſtacle to arreſt its motion, that obſtacle would be the pin, *x*, in the front plate, if there were no other interpoſed before it had fallen ſo far back, but if the ſnail is in any other poſition than that, wherein its neareſt indentation towards the centre is contiguous to the pin of the rack-tail, the tail-pin of the rack will fall upon the edge of the ſnail before the rack has fallen back to the pin, *x*, and all the teeth of the rack will not paſs the catch of the hawk's-bill in this caſe, but juſt ſo many as there are indentations or ſteps counted from the remote angular point of the ſnail to the ſtep on which the tail pin reſts; in the preſent poſition, in the plate, the tail-pin is reſting on the ſtep ſix of the ſnail, which denotes that ſix ſtrokes will be given by the hammer, or that ſix teeth of the rack are to be gathered up by as many revolutions of the hawk's-bill; but we ſee that only five teeth remain to be gathered up of the rack; hence we know that the clock has ſtruck one out of ſix, and is in the act of ſtriking; accordingly, we ſee that the pin in the hour-wheel, *g*, has juſt raiſed the warning-piece and permitted it to go again; the clock will therefore now continue to ſtrike till the upper end of the gathering pallet, *s*, falls on the projecting pin, *m*, of the rack, which will be as ſoon as the laſt tooth of the rack is drawn up to the hawk's-bill, in which ſituation the wheel, Q, cannot revolve any farther till another hour has elapſed. After another hour is paſt, the pin of the wheel, *g*, will elevate the warning-piece, *v*, the bent end, *t*, of which will firſt be raiſed out of the way of the pin of the wheel R, and the fly will run on a revolution or two, with a whiſtling noiſe, *i. e.* the clock will *give warning;* but the end, *p*, of the hawk's-bill has not yet been raiſed far enough by the preſſure of the end, *t*, of the warning-piece, to make the catch, *q*, clear the teeth of the rack, therefore the rack cannot yet fall back; preſently, however, the hawk's-bill is lifted high enough by the pin of the pinion of report, *g*, which has a ſlow motion; the rack falls back till its tail-pin reſts on ſtep ſeven nearer the centre, which has now arrived at the point of contact, and therefore ſeven teeth of the rack paſs the catch, *q*, in the fall of the rack, and the hour of ſeven is now ſtruck before the tail of the gathering pallet, *s*, falls again on the pin, *m*, of the rack, and ſtops the ſtriking; at the ſame time the bend of the warning-piece catches the pin of the wheel R, and ſtops the fly; and in this way any number of hours will be ſtruck by the hammer on the bell that the ſnail regulates, which we have ſaid revolves once in every 12 hours; and if any other cauſe than the pin of the hour-wheel, *g*, ſhould lift the warning-piece within the hour, counting from warning to warning, the ſame number of ſtrokes will be repeated, though it ſhould be a hundred times or more. To convert this ſtriking mechaniſm into repeating mechaniſm, therefore, it is only neceſſary to place a lever, *y*, to revolve round a ſtud on the front plate of the frame at the point *y*, with a ſlender ſpring, *z*, over it to bring it back to its original ſituation, when the end placed under the warning-piece is elevated by depreſſing the exterior end, which may be done by pulling a ſtring down which is tied to a hole in this end, as repreſented in the figure; and as often as the ſtring is pulled, ſo often will the clock repeat the ſtrokes of the current hour. There is yet remaining the three armed piece, 1 2 3, undeſcribed, called *ſtrike* or *ſilent*, the uſe of which is explained by its name; this piece is differently made in different clocks; in the clock before us it is moveable on a ſocket, riveted to the end, 3, of one of its arms, round a ſtud in the front plate of the frame, and as the ſocket has ſcarcely any ſhake, the other two ends, 1 and 2, move always in the ſame plane; at the end marked 1, is a pin projecting above the upper circumference of the face or dial of the clock, ſo that it may be moved to the right or left at pleaſure, when the glaſs-door is open; the end marked 2, has a ſlope, like a wedge, on that ſide which is next to the plane of the frame-plate, and the end of the arbor, O, in *Plate* XI. of the warning-piece, projects ſo far as to touch the inclined plane; this arbor of the warning-piece has ſome ſhake, in the direction of its length, within the frame, and its poſterior pivot paſſes between the prongs of a forked ſpring, X, which, reſting againſt the ſhoulder of the pivot, puſhes it cloſe to the interior ſide of the front plate of the frame, where a ſimilar ſhoulder ſtops it; when the pin, at 1, is puſhed to the right, the wedge of the end, 2, puſhes the arbor back, notwithſtanding the forked ſpring, X, juſt deſcribed, and the end, *v*, of the warning-piece, being carried with its arbor nearer to the frame than it otherwiſe would be, falls in the way of the pin of the hour-wheel, *g*, and the clock conſequently ſtrikes the hour regulated by the ſnail; but when the pin, at 1, of the ſtrike or ſilent, is puſhed to the left, the end, 2, is withdrawn from the pivot of the arbor on which the warning-piece is faſt, the ſpring, X, in the frame puſhes it forward ſo far, that the end, *v*, of this warning-piece is clear of the pin of the hour-wheel, *g*, which wheel therefore continues to revolve from hour to hour in a ſtate completely detached from the mechaniſm of the ſtriking part, which we have been deſcribing. Sometimes there is a hand moveable in a ſmall circle in the dial, which anſwers the ſame purpoſe as the pin at 1; (See CLOCK-*work*,) but this is generally the caſe when there is no circle for the ſeconds, or when there is ſome other circle to which it is intended to correſpond, for the ſake of uniformity, which is generally attended to in the dial-work of every clock.

Laſtly, the four holes in the front plate denoted by the letters Z, Z, Z, Z, are the holes in which the pillars of the dial, or face, are inſerted and pinned within the frame by metalic pins going acroſs the ends that paſs through the plate of the frame; ſo that the face is thus firmly attached to the frame, and then the frame to the caſe, which preſerves the wheel-work from duſt, and the touch of ſuch perſons as might otherwiſe ſatisfy their curioſity at the expence of ſome of the more delicate parts of the workmanſhip. Indeed, many of the ornamental portable clocks have caſes of glaſs, with various devices, ſuch as are calculated to recommend them to the fancy rather than the judgment of their purchaſers, who wiſh to adorn thereby their chimney-pieces. In the formation of theſe ornamental caſes, ſpar of different colours, or moulu, and various other ſuperb materials are uſed, agreeably to the taſte of the artiſt who is employed in ſuch manufactory.

A portable clock, ſuch as we have here deſcribed, is eaſily converted into a clock with a long caſe, and a ſuſpended weight for the maintaining power, by ſubſtituting a cylindrical barrel for the fuſee on the arbor of the great wheel, on which barrel the chain is wound, inſtead of being made to ſurround the fuſee; for, as a ſuſpended load acts at all times with the ſame power, it is neceſſary that the barrel ſhould have the ſame diameter at every part of it. Of this conſtruction are the eight days houſehold clocks in general uſe.

use. Also by introducing a wheel and pinion between the great and centre wheels, the clock may be made to go a month or more, and by introducing two such wheels and pinions, it may be made to go a year at one winding up, with a maintaining power proportionably great.

Eight-days portable Clock, with Chimes and repeating Mechanism.

Under our article CHIMES, we gave a description of the chime-barrel, hammers, and bells of a chime-clock, in a detached state, but referred to our present article for their connection with the striking part of the clock, which could not there be sufficiently explained; as we have now shown the manner in which the modern striking part is constructed, and have also explained the nature of its action, we propose to resume the subject of chimes, for the explaining of which in the best manner, we have thought it necessary to describe here at full length, a portable chime-clock with a short pendulum, for which purpose we have introduced two separate views in *Plates* XVI. and XVII. of *Horology*, which, we trust, will enable us to make all the mechanism, complex as it may appear, sufficiently intelligible to any one who has read and understands the structure of the eight-days clock that has been just described. *Plate* XVI. is a representation of the three movements of a chime-clock, when the front plate of the frame is taken off, the eye being placed perpendicularly over the mechanism when viewed; we have retained the same letters of reference as we used in *Plate* XI., as far as they will go, and have supplied the deficiency from the Greek alphabet, which are used for the movement of the chimes, so that the reader will see, by a *coup d'oeil,* the arrangement of the movements, even without the help of a description, if he recollects the parts of the clock described in *Plate* XI. A, A, A, A, stand at the four corners of the back plate of the frame, on the interior surface; B, B, B, B, are the places of the four pillars; C the spring barrel of the going part; D that of the striking part, and α that of the chime portion; E is the great wheel and fusee of the going part, F those of the striking part, and β those of the chime part; N in each the catch of the guards respectively; G, H, and I, are the wheels which, with their respective pinions, constitute the train of the going part, of which H is the contrate wheel, and I the balance wheel, with its lower pivot resting on the small cock or potence K; the pallets cannot be well seen in this plate, but are visible in *Plate* XVII.; P, Q, and R, are the wheels of the striking movement, having each a pinion on its arbor, and S is the pinion of the fly seen at S in *Plate* XVII. The wheel P has the eight pins for lifting the hammer, the arbor and levers of which are at T; the arbor of Q carries as before the gathering pallet for drawing up the rack of the striking part, and R has the pin for catching the bent end of the warning piece; W is the hammer tail spring, and U the counter spring, which are somewhat differently placed here from what they are in *Plate* XI., but act in a similar manner. The wheels marked with the Greek characters $\gamma, \delta, \varepsilon, \zeta$, are those of the chime movement, with their respective pinions; δ is the wheel on the arbor or axis of the barrel, which has the lifting pins for moving the hammer tails when they strike the bells, as has been already explained under our article CHIMES of a *clock*; θ is placed near the hammers, ι on the bell of smallest diameter, and $\varkappa$ at the springs which bring the hammers back after each blow, and hold them in a situation to be caught by the pins of the revolving barrel.

Let us turn now to *Plate* XVII., where we have a perspective view of the whole frame and mechanism before the front plate, with the same letters of reference, as far as they go, as in *Plate* XII., and also as in *Plate* XVI., and where the Arabic figures are put to the mechanism of the chimes that connects them with both the going and striking parts of the clock. In this plate, which is intended to explain the ordinary chime-work of a clock, the parts of the mechanism which effect this purpose are so disposed as to be nearly all seen in their respective places of action. A, A, are placed on the back plate of the frame; B, B, B, B, are the four pillars of the frame; C, D, and α, are three ratchet wheels for adjusting and preserving the intensities of their respective main-springs, and are placed before the front plate on the squares of their barrel arbors, as in any other portable or spring clock; E, F, and β, are the arbors of the three fusees for the key that winds them up; L and L are the parts of the two guards which are attached to the front plate, on the interior side, out of sight, the situation and action of which were explained under *Plate* XI., and the end of the third guard is hid by the snail. K is the bridge of the dial-work, concealed from sight, such as is seen at the bottom of *Plate* XII., in *fig.* 3; I is the crown-wheel and pallets, to the verges of which the crutch of the pendulum is fastened behind the frame; and S is the fly of the striking part, held by a small spring crossing the middle of its arbor near S, by simple friction. The cannon pinion is hid from sight behind the 12-hour wheel *i*; but the pinion that acts with it, of the same number of teeth, is seen at *g*, which is called the pinion of report, and has a pinion of 6 on its arbor pivoted into the cock *h*, and driving the 12-hour wheel of 72 teeth, as in the preceding clock; the snail, however, of the striking part, is not here on the 12-hour wheel as before, but is attached to a star, or wheel with 12 pointed teeth, at *l*, one of which teeth is actuated each hour by a pin in the cannon pinion, and the foot, *f*, with a slender spring, *e*, pressing against its leg, the heel of which is placed between the two nearest teeth of the star, not only prevents their backward or forward motion during the lapse of each hour, but also yielding to the impulse given by the pin of the cannon-pinion at the end of each hour, allows the tooth to pass the heel, and then returns to its original situation by the force of the spring *e*, at the same time pushing on the star the exact space of one interval, so that when the star moves at all, it must necessarily move just one twelfth part, and remain in that situation together with its snail, for the space of a whole hour before it is moved again, which is an essential condition where the striking part repeats the hour; otherwise the following instead of the preceding hour might be struck by the clock during each latter half-hour of the day. The tail of the warning piece does not here reach to the pin in the pinion of report as in our former striking work, explained in *Plate* XII., but has the chime-mechanism interposed; in consequence of which arrangement the chimes play first, and then set the clock a striking when they have ceased, at the end of every hour; for this purpose two separate racks with their respective springs, catches, and gathering pallets, &c. are necessary in this machine, which may have their respective offices thus explained: The pinion of report, *g*, goes round in an hour, as we have seen before, and has 4 pins which raise the cross lever, 1, of the hammer, 1, 2, every quarter of an hour, a little before its completion; at the same time that the cross lever, 1, is lowered, the end, 2, of the hammer is depressed, and its tail-piece in contact with the spring, 3, is raised, by reason of its being placed behind the stud which is at the centre of motion; the spring, 3, consequently is raised also from its state of rest, so that when the pin of the pinion of report lets go the lever, 1, this spring, 3, pressing back the hammer-tail, makes its head, 2, strike a

piece of

projecting pin near the claw of the detent or catch, 7, after which it falls back again by its own weight; this stroke of the hammer is powerful enough to drive the claw of catch 7 from the teeth of the chime-rack, 4, which therefore immediately falls back, by the force of its spring, 6, pressing on its projecting end beyond the stud, round which its motion is performed, until its tail, 5, falls on the nearest of the four steps of the small snail of the quarters attached to the pinion of report; in this fall as many teeth of the chime-rack pass the claw of the catch as there are steps in the small snail, counted from its remote angular point to the end of the tail-piece of this rack; the greatest fall of the rack is the space of four teeth, when its tail rests on the step nearest the centre of the snail for the first quarter of an hour, and when its lever falls back against the pin, 11, in the front plate of the frame; in the mean time the supporting bar, 8, moveable on a stud near its lower extremity, having been forced back by the long tail of the gathering pallet, 10, of the chime movement, now returns by the action of its spring, 9, pressing its tail-piece below the centre of motion, and presents its head to a second pin in the catch, 7, nearer its centre of motion, contiguous to the figure 7, so that when the catch, 7, falls back by its own weight after it has been struck by the hammer, 2, its second pin falls on the head of the support, 8, where it remains until the rack of the chimes has its tail placed on the step of the small snail; the chime movement, being at liberty as soon as the tail of the gathering pallet, 10, falls from a pin behind the chime-racks, not seen in the drawing, runs on, and presently the said tail of the pallet pushing against the inner side of the support, 8, disengages the second pin of the catch 7, the claw of which now falls again into the teeth of the rack, and holds the rack while the pallet has drawn it home again, *i. e.* till the tail of this pallet falls on the concealed pin on the back of the chime-rack, the chime-barrel in the mean time revolving and raising the hammer-tails of the eight concentric bells fixed on a common arbor at 1, and supported by a bar attached to the front plate of the frame. This process is repeated three times at the quarters 1, 2, and 3; but when the hour is completed nearly, the fourth process does not stop here; for as the chime-snail now permits the rack belonging to it to fall back by its spring, 6, the space of four teeth, the pin in the left hand end of this rack strikes the tail, *p*, of the hawk's-bill, *q r p*, moveable on a stud at *r*, and thus raises the catch- or bill, *q*, from the teeth of the striking rack, which now falls back as far as its snail, *l*, will allow its tail, *n*, to come towards its centre; when the hawk's-bill is lifted in this manner it pushes up the bent end, *t*, of the warning-piece from the pin of the wheel, R, in the frame, (*Plate* XVI.) and the fly makes two or three revolutions or more, which motion produces the noise of warning, but the little spring, 13, immediately pushes the warning-piece down again into the way of the pin of wheel R, the motion of which is thus presently stopped: the chimes of the hour are now going on while the four teeth of its rack are in the act of being drawn home, and when the fourth tooth of this rack is brought back, the chime-pallet falls on the concealed pin of the rack behind it, and nearly at the same time the pin of the rack in front, which pushed down the tail, *p*, of the hawk's-bill, now raises the tail, *v*, of the warning-piece, *t v*, and consequently depresses the end, *t*, of the same so far, that the pin of the wheel R is again free, and the striking of the clock goes on as in the usual striking part, till the hour regulated by the 12-hour snail is counted by the proper number of strokes; after which the tail of the gathering pallet, *s*, of the hours falls on its resting pin behind the hour rack, *m u*; it being a matter of no importance on which face of the rack this pin is fixed; nor yet on which side of the bill, *q*, the gathering pallet is placed, provided there be the proper number of teeth in the rack to be drawn up by the pallet. The four holes, *a*, *b*, *c*, *d*, are to receive the four pillars of the dial; the horizontal lever, *y*, taking the pin of the catch 7, may have its tail, *z*, pulled by a string coming through the case, to make the chimes repeat, and the hour also at any time during the first quarter after striking; and, lastly, the pin of the lever 14 15, or strike and silent, by being pushed to the right or left, will bring the heel of the part 15 to a pin in the middle of the hammer lever, 2, or remove it therefrom accordingly as the chimes and striking are to be in use, or the contrary. After what we have already said about trains, we think it not necessary to particularise the numbers of teeth in the wheel-work.

A Clock without Dial-work, by Dr. Franklin.

When clocks had begun to be common, and a variety of complicated contrivances had been introduced into the different constructions, it was at length deemed desirable to simplify the mechanism; and various attempts have been made to construct a clock with as few wheels and pinions as possible. The late Dr. Franklin, and the late Mr. J. Ferguson both succeeded in diminishing the usual number of wheels and pinions to three of the former and two of the latter, notwithstanding hours, minutes, and seconds, were all indicated by their contrivances; we propose to describe them in succession, and shall begin with Dr. Franklin's first, as being prior in point of time. *Fig.* 1, of *Plate* XVIII, of *Horology*, will explain so much of Dr. Franklin's clock, in question, as is necessary for conveying a suitable idea of its construction. The face, or dial plate, is perfectly represented, and the dotted circles denote the wheels and pinions in the frame behind the face, on a supposition that the face and front plate of the frame are transparent; which mode of representation not only places every wheel and pinion in its own place, but shows their respective diameters as well as if a second figure had been used for this purpose, as has hitherto been usual, when this clock has been described by other writers. The great wheel, A, of 160 teeth, goes round, by means of the cord with a suspended weight surrounding a pulley attached to it, in four hours; this wheel drives a pinion, B, of ten leaves, in $\frac{10}{160}$ of four hours, or one quarter of an hour; on the arbor of this pinion is the second wheel, C, of 120 teeth, actuating a second pinion, D, of 8, in $\frac{8}{120}$ of a quarter of an hour, which is one minute, and together with it, on the same arbor, the third wheel, E, of 30 teeth, in the same time; this third wheel is the usual swing-wheel of an ordinary 30-hours clock, and has a seconds pendulum, suspended in the usual way from a cock, by a piece of the main-spring of a watch. These are all the wheels and pinions made use of in the clock. The face is occupied by a spiral line, as seen in the figure, and has the hours denoted by the Roman characters, which count from XII, in the order I, II, III, &c. as the spiral goes, placed at intervals of a quadrant from each other; these hours, as well as the 60 minutes, placed four times over in a surrounding circle and denoted by the Arabic characters, are pointed to by a hand, P, placed by friction on the round part of the protruding arbor of the great wheel, A, that revolves in four hours. In the present situation of this hand, the time indicated is forty minutes past one of the three hours which it has last passed. *viz.* XII, IIII, or VIII, and it is presumed that a mistake of four hours can hardly happen whenever the clock is examined. The small hand at D indicates seconds in the usual way, and therefore requires no explanation. There can be no doubt but that a clock thus constructed will measure time as well as any other clock with a similar pendulum, provided it be well made. The objections which have

have been alleged against this construction are, that it is possible a person awaking in the night, and examining such a clock, may mistake his time four hours very easily; and that that it will require being drawn up by its cord once every day, unless, indeed, the fall of its suspended weight should be made much greater than is usual, or even convenient, in the generality of houses. The writer of the present article had some years ago a clock, constructed nearly similar to the present one, but its great wheel revolved once in every three hours, which allowed larger minute spaces in the surrounding circle, and required an additional spiral line; for the Roman figures were four deep at each third part of the circle; its use was to keep in motion the system of Jupiter and his four satellites, which it did very well; an endless cord, with a detached ratchet, being applied to produce continual motion during winding as well as at other times. We do not learn, however, that Dr. Franklin's clock has been frequently copied.

A Clock with only three Wheels and two Pinions, by Mr. J. Ferguson.

We have said that Mr. J. Ferguson also contrived a clock to show hours, minutes, and seconds, with only three wheels and two pinions; his principal object was to obviate the objections we have stated to Dr. Franklin's clock; *fig.* 2 of *Plate* XVIII. gives a similar representation of Mr. Ferguson's clock, as *fig.* 1 does of Dr. Franklin's: the great wheel, A, of 120, revolves in 12 hours attached to the pulley, round which the cord of the weight is stretched; this wheel drives the pinion, B, of 10 leaves, in $\frac{10}{120}$ of 12 hours, or in an exact hour, which is the value of this fraction; the second wheel C, which revolves also in an hour, and which has also 120 teeth, drives the second pinion D, of 6 leaves, in $\frac{6}{120}$ of an hour, or in three minutes; consequently the pallet-wheel of 90 teeth, placed on the arbor of this latter pinion, revolves also in three minutes; the pallets of the anchor escapement, which act with this wheel, give an impulse to a seconds pendulum at each vibration, as is usual when the swing-wheel has only 30 teeth. The hours are marked in Roman characters, on a circular plate that is inserted by friction, on the arbor of the 12-hour or great wheel, about three of which hour figures appear always through an aperture cut through the dial below the pinion B: and a fleur-de-lis, designed on the dial, serves as a hand to point to the hour to be indicated. We see no reason why a circle, a little smaller than the plate of the hours, might not have been marked with the Roman characters on the dial itself, within the circle of minutes, with a hand placed on the arbor of the 12-hour wheel to point to it as usual, which method is certainly more simple, inasmuch as that the circular small plate would have been dispensed with and also the aperture in the dial. There is also another circular plate, divided into 60 three times over, and marked with the Arabic figures, placed by friction on the arbor of the three minute or pallet-wheel F, which is pointed to by another fleur-de-lis on the dial, as seen through another aperture of one third of a circle in length; this large plate, borne by the pivots of the pallet-wheel, must have been very injurious to the performance of the clock before us, where the power is diminished in the ratio of 720 : 3, supposing the pallet wheel no bigger in diameter than the pulley, and that independently of friction; the inertia of so much matter as the seconds plate must contain, to be overcome at the return of each vibration, must have required a large maintaining power; an objection of which the inventor himself acknowledges the existence; this objection, however, might very easily have been obviated, for a circle as large as the divided plate might have been drawn on the upper half of the dial, and would have admitted of similar divisions and figures to which a hand, borne by the pallet-wheel arbor, would have pointed, and indicated the seconds as truly as they are at present. The inventor, not aware of so simple a resource, proposes to get rid of the force of the objection by omitting the seconds altogether, as being of no real service except in astronomical clocks; but why attempt the introduction of seconds at all, when studying simplicity, if they are of no use? Mr. Ferguson has also allowed another objection to his construction, from which Dr. Franklin's was exempt, namely, that when the minute hand is at any time adjusted, it does not alter the hour plate, which must have a separate rectification, for effecting which conveniently he had 12 holes drilled in the small 12-hour plate at equal distances, to receive the end of a pin whenever the hour-plate required adjustment; the seconds plate must also have been subject to a similar inconvenience. Mr. Ferguson has himself candidly stated one other objection to his clock, that seems to afford a better proof of his candour than of his judgment in clock-work, which is, that he supposes the total arc of vibration of the pendulum must be too small with such diminutive teeth as the highly numbered pallet-wheel afforded, and seems to have thought that a large arc is better than a small one, by reason of the greater momentum of the pendulum, notwithstanding he mentions a cycloidal arc as that in which all lengths are equally isochronal: the fact however is, as is now universally allowed and proved in practice, that a small arc near the point of the pendulum's quiescence approximates the nearest of any other part of a circular vibration to a cycloidal one, and that the momentum, which is not acquired by velocity, may and ought to be made up by the weight of the ball, moving in nearly as small an arc as the escapement will admit, to sustain a continuance of the vibration.

A Clock for exhibiting the apparent daily Motions of the Sun and Moon, and State of the Tides, &c. by Mr. J. Ferguson.

Among the other ingenious contrivances, described in Mr. Ferguson's "Select mechanical Exercises," is the clock of which we have just given the title, the simplicity of which has recommended it to the notice of various writers and compilers of dictionaries, and induces us to give it a place in our collection. *Fig.* 3. of *Plate* XVIII. is a reduced copy of the dial of the clock under our present consideration, *fig.* 4. the dial-work, or wheels and pinion connected with the going part of a common 30-hours, or eight days clock, and regulating the motions of the different hands, plates, and contrivances for representing the ebbing and flowing of the tide at any given place. The pinion of 19 leaves, in *fig.* 4, is attached to an arbor which revolves in eight hours, by its connection with the wheel-work within the frame, which revolution may be effected by a wheel of 64, taking into a pinion of eight leaves on the centre wheel arbor; then, as three times eight are 24, three times 19 are 57; the wheel of 57 consequently revolves in 24 hours, with its centre in the centre of the dial; a second wheel of 59 teeth (*viz.* $29\frac{1}{2} \times 2$) is also actuated by the same pinion of 19 in $\frac{59}{19}$ of 8 hours, which time is $24^h\ 50^m\ 526$, or $24^h\ 50^m\ 31^s.58$; this wheel is of precisely the same diameter as the wheel of 57 teeth; and these two wheels, which are all that are necessary for producing the relative aspects on the dial, may be called, that of 57 the *solar*, and that

that of 59 teeth the *lunar* wheel. The lunar wheel, which lies next to the clock frame, has a solid arbor, but the solar wheel, which covers it, has a tube just fitting this arbor, and turning on it without shake; the tube is shorter than the arbor and carries the small circular plate represented by *fig.* 5, that has the 24 hours in Roman characters, and within these the 29½ days spaces of the moon's age in Arabic figures: all equally divided; the attached piece, S, is the sun's representative, which thus revolves from the upper XII. in *fig.* 3, to the same again in 24 solar hours. On the face of this small revolving dial is put a darkened ring, gradually increasing in breadth half way round, and as gradually decreasing the other half way. Over this revolving plate of 24 hours and 29½ days is placed another small plate (marked twice with the words *high water*, and as often with the words *low water*, also with *moon's age*, &c. as seen in *fig.* 3.) upon the arbor of the lunar wheel, so as to be adjustable on its round part by friction merely; this lunar plate has an aperture near its circumference, through which appear about five hours on the solar hour plate, and also a small circular hole, within the former, as it regards the centre of motion; this plate has, moreover, the figure of an ellipse darkened on it, which is nearly covered by a smaller circular plate, with concentric circles, borne by a supporting wire attached to it at one end, and at the other, when bent a little, to the principal dial-plate near the lower XII., as seen in the figure. The use of the small circular hole in the lunar plate is to show the phase of the moon in any part of its synodic revolution; for when in the situation F, *fig.* 5, as it regards the solar plate, no part of the darkened ring appears; which phænomenon denotes full moon a little short of the fifteenth day's age; when it is at N, the dark part of the solar plate or ring covers it entirely at 29½ days age, which position denotes new moon, and at 90° from these situations at both sides, one half is dark and the other half light, which aspects denote the quadratures. The sun, S, attached to the solar plate is the index for solar time marked on the large hour circle of the principal dial, and the moon, M, pointing to the same, indicates the 24th parts of the earth's rotations, as they relate to the moon, which may be called so many lunar hours; 24 of which by this mechanism, we have seen, is upwards of 50½ solar minutes longer than 24 solar hours. From the small circle of the moon is carried a straight wire over the hours of the solar plate, to indicate the mean time of the moon's mean passage over the meridian on any day of her age; and at the space of 2½ hours behind is another similar one, to point out the time of a mean high water at London Bridge, which might be set to a distance, behind or before, corresponding to any other place on the globe, that has two tides in somewhat less than 25 hours. The stationary small plate in the centre is intended to represent the earth, and the dot, L, between the fiftieth and sixtieth parallel of latitude, represents London, with respect to which place the position of the ellipse or tide-piece is altering its position visibly every hour, agreeably to the words marked on the lunar plate. On the back of this lunar plate is likewise another ellipse of solid brass D, placed concentrically, which, revolving with it, lifts the lever E, moveable on a stud at F, when either of the ends comes in contact; but when the sides are presented the said lever falls below the horizontal position; when this lever, F, is thus raised and lowered, twice in each lunar day, it carries with it the attached plate, H, above it, when kept in a perpendicular position by the four friction rollers, R, R, R, R, which plate has the sea painted on it, as seen in *fig* 3, over the dial at H. The representation of the phænomena depending on the relative positions of the sun and moon thus simply effected, affords a pleasing object for the eye at a trifling expence; but we are not to expect great accuracy when we consider how many equations are required to reduce the mean places of those two luminaries, particularly of the latter, to the true apparent places. Mr. Ferguson made this mechanism so as to be capable of being actuated by a watch on the fusee arbor of which a pinion of 20 was placed to drive a wheel of 40 round, on the arbor of which 40 was fixed the pinion of 19 that has been described as revolving in 8 hours, which it would do in this case, provided the fusee itself revolve, as is usual in common watches, in the space of four hours.

There is, however, an inaccuracy in the numbers of the wheel-work adopted in the dial-work of this clock, which would render it too imperfect to be used for a considerable length of time without a new rectification, even provided the motions of the sun and moon, or, more properly speaking, of the earth and moon, were quite equable, as the construction supposes, which inaccuracy may thus be explained; as the pinion of 19 drives both the wheels of 57 and 59, when the former has performed a revolution in a solar day, the latter falls two teeth short of a revolution, which it completes not until two teeth of the second revolution of the wheel 57 have been again impelled, so that in every 24 hours the little moon loses $\frac{2}{59}$ of its revolution, which is a part of a relative retrograde motion, as it regards any point, for instance the upper hour XII. in the solar plate; so that as often as 2 are contained in 59, so many day-spaces must there be on the solar plate, figured in a retrograde direction, as the figures regard the principal plate; but the value of $\frac{59}{2}$ is 29½ exactly, which number of days measures the lunation according to these wheels exactly; there is, therefore, a monthly error of $44^m\ 3^s$ almost, which will amount to nearly an entire day in the short space of about 32 lunations.

But there is, moreover, a practical objection to the two wheels, 57 and 59, being both driven by the same pinion of 19, which is, that being of the same diameter, the distance between their teeth is not the same in both, one being $\frac{1}{57}$, and the other $\frac{1}{59}$ of a semicircle, supposing their teeth and spaces to be respectively equal to one another, but if both wheels are cut in the cutting-engine by the same cutter, the inequality will fall in the teeth entirely; in either case the action of one of the wheels must be bad if the other is properly proportioned, and periodic jerks will be the consequence, which, in wheel-work going by a clock or watch movement, ought to be avoided. Whether or not Mr. Ferguson had the dial of the Hampton-Court clock in his eye when he contrived the simple mechanism of this clock, we will not undertake to affirm, but we think it extremely probable that he had, particularly as he has copied the position of the annual train in another of his clocks, as we shall have occasion to shew, under our article DIAL-*work*. Being in the habit of calculating numbers proper for representing given periods of time in clocks, watches, orreries, &c. we have turned our thoughts towards the improvement of this clock, as well as of other pieces of mechanism, so far as relates to accuracy, and beg leave to lay before the reader the alteration that has occurred to us, for rendering the clock before us more perfect than it is in the state we have described it.

When describing the Hampton-Court clock we endeavoured to prove that when the moon's age is indicated by the difference of the velocities of the two hands, moving in the same direction, and representing the sun and moon, the latter ought to pass the XII. o'clock point, on each day $50^m.473$ nearly later than on the preceding day; but by

 Mr.

Mr. Ferguſon's calculations we ſee the daily retrogradation is $50^m.526$, and the difference .053 amounts to an entire day's motion in a little more than 952 days, or ſomewhat upwards of 32 lunations, as we have ſtated. What therefore we want, in this caſe, is a couple of diviſible numbers that ſhall be to each other very nearly in the ratio of 24^h to $24^h\ 50^m.473$, which numbers, by a peculiar arithmetical proceſs, become familiar to us by practice, we have determined to be 2368 : 2451. Theſe are the neareſt poſſible numbers that can be got without aſcending higher in the ſcale of continual ratios, and are luckily capable of reduction into compoſite numbers thus; 2368 taken as a product is equal to 74×32 and $2451 = 57 \times 43$; therefore the train $\frac{43}{74} \times \frac{57}{32}$ will be the wheel-work required; the ſolar wheel of 74 teeth being made to revolve with a tube as an arbor in 24 hours, by the clock-movement, muſt impel the wheel of 43 placed on a ſtud, or otherwiſe on the front plate of the frame, at one ſide of it, and this wheel of 43 muſt have the next driver, 32, pinned to it, to impel the laſt wheel, 57, or lunar wheel, placed on a ſolid arbor, concentrically behind the ſolar wheel, according to Mr. Ferguſon's poſition, and the dials and other deſigns of the clock face may remain preciſely as deſcribed; ſo that inſtead of the pinion of 19 impelling two unequal wheels at once, we ſhall have a pair of ſmall wheels pinned together, one impelled by, and the other impelling its fellow, where the motion muſt be taken from an arbor of 12 hours, carrying a wheel of 37 to actuate the 74 in 24 hours, inſtead of from one of eight hours, as Mr. Ferguſon propoſed; which mode is equally practicable. As a proof of the accuracy of our calculation, we have by direct proportion as 2368 : 2451 :: $24^h : 24^h\ 50^m.4729729$, &c.; hence the deviation from the data is here only .0000271 of a minute in each lunar day, which will not amount to an error of an entire day in leſs than 1,862,472 ſuch days, and therefore may be aſſumed as no bad ſubſtitute for the truth itſelf; ſeeing the clock will never be expected to go ſo long without cleaning or ſtoppage from ſome external cauſe.

Should it occur to the reader that 32 lunations conſtitute a period long enough for the clock of Mr. Ferguſon to go, before a new rectification, we beg leave to ſuggeſt to him, that in the ſpace of a lunar day there are two tides and two ebbs, conſequently an error of three-quarters of an hour in each lunation will place the tide-plate, H, three hours wrong in the ſpace of about four months, and in nearly eight months an high-water will be changed into low-water, and the reverſe in the next eight months, which is certainly an indiſpenſable error.

That the clock-maker may not be at a loſs how to apply the remedy we have propoſed for the inaccuracy of Mr. Ferguſon's ſolar and lunar wheels, we ſhall conclude our deſcription of the clock before us with an account of the exact dimenſions of the parts propoſed to be ſubſtituted. If we take the wheel of communication of 37 teeth at 12 per inch, meaſured at the pitch line, its geometrical diameter will be .98 or $\frac{98}{100}$ of an inch, and its practical diameter, with the addendum for the ends of the teeth, 1.04, as may be ſeen by inſpection in our Table of Diameters, under the article Clock-*making*; the wheel of 74 being double will have its geometrical diameter equal to 1.96, and its practical one 2.02; the fellow of this laſt or ſolar wheel has its geometrical diameter by the ſame proportion, 1.14, and its practical one 1.20; the diſtance of the ſtud from the centre of motion of the ſolar and lunar wheels, muſt neceſſarily be the ſum of the geometrical radii of theſe two laſt wheels, namely $\overline{1.96 + 1.14} \div 2$ which is $= 1.55$; again the ſum of the geometrical radii of the remaining two wheels, 32 and 57, muſt be alſo equal to 1.55, in order that the centres of motion of the ſolar and lunar wheels may exactly coincide; but a wheel of a geometrical diameter, equal to $\overline{1.55 \times 2}$ or 3.10 inches and of $\overline{32 + 57}$ or 89 teeth, will have only about 9 teeth per inch, according to our table, and the practical diameters of wheels 32 and 57, by the ſame, will be reſpectively 1.21 and 2.1. The calliper ſuitable for theſe proportions and dimenſions is given, of half their full ſize, in *fig.* 2, of *Plate* X. which needs no further explanation, except that the wheels, 43 and 32, are ſo nearly of a ſize that one circle repreſents both, as pinned together, and revolving with a contemporary motion round a ſtud or ſcrew in their centre, going into the front plate of the clock-frame. The ſmall wheel of 32 acts deeper into the teeth of its fellow than the 43, by reaſon of having larger teeth than the other, though the wheel is of the ſame ſize.

Equation Clock by Enderlin, ſhewing alſo the relative Situations of the Sun and Moon, &c.

In our hiſtory of the ſucceſſive improvements in clocks, we have mentioned the names of various ingenious men who contrived mechaniſm for exhibiting on the dial of a clock both mean and apparent time, and conſequently the equation of time, which is the difference between theſe; to give drawings and deſcriptions of all the different methods of producing ſuch an effect, would be like throwing ammunition at a dead mark; but to gratify the wiſhes of the curious, in a certain degree, we propoſe to ſelect a clock of this kind, made on the continent by Enderlin, which appears to us to merit a deſcription better than moſt of the others.

Fig. 1, of *Plate* XXIV. of *Horology*, exhibits the plan of the mechaniſm which conſtitutes the equation-portion of Enderlin's clock (See Traité de Thiout, p. 252, *Pl.* XXV.) and *fig.* 2, is an exact repreſentation of the dial and hands; we will begin with *fig.* 1, or poſterior plane of the dial, where the motion is communicated from the wheels within the frame, and proceed, in the order of the communication of this motion, through the different parts of this figure. The ſmall wheel Q, of 24 teeth, borrows its motion from the movement of the ſtriking part, in order that the going part may not be impeded by cumberſome additions; this wheel is not repreſented as a contrate wheel in the original, which we have copied on a reduced ſcale, but would act better if it were; it impels the ſmall wheel R, of 32 teeth, with a vertical arbor, held to its poſition by a ſmall cock, T, on the front plate of the frame, which arbor has a bend and compound joint, below T, and a ſecond ſimilar cock above, that keeps the lower half of the arbor in its poſition, while the upper and lower ends, or pivots, bear in their reſpective cocks, which it is not neceſſary to inſert in the figure; this arbor has a ſingle endleſs ſcrew, S, on the middle of the inclined half, actuating a large wheel A, of 487 teeth, and alſo a pinion *a*, of 24 leaves, at the lower extremity, actuating a ſmall wheel V, of 32 teeth, and making this revolve, we are told, in 24 hours. From theſe data we can now calculate the periods of the other wheels that have been mentioned; if V revolves in 24 hours, *a* revolves in $\frac{24}{32}$ of that time, namely, in 18 hours, and with it the bent arbor R T S *a*; alſo the ſmall wheel, Q, revolves in $\frac{24}{32}$ of 18 hours, or in $13^h\ 30^m$, by means of its connection with the ſtriking part, which may eaſily be effected by proper numbers in the teeth of the connecting wheel and pinion; likewiſe the large wheel A, of 487 teeth, revolves in $\frac{487}{1}$ of 18^h, which time reduced, is 8766 hours, or $365^d\ 6^h$; this wheel,

wheel, therefore, is called the *annual* wheel. The wheel X, with 62 inclined teeth, and the wheel Z, with 90 teeth, revolve feparately round one common centre 5, and are impelled, the former by a fingle tooth on the 24 hours arbor of the fmall wheel V, and the latter by another fingle endlefs fcrew Y; this fcrew Y has a pinion 6, of 21 leaves, on its upper end, impelled by the pinion *a* of 24 in $\frac{2}{3}\frac{1}{4}$ of 18 hours, which period is $59^d\ 1^h\ 30^m$ or the fum of two lunations, where each is $29^d\ 12^h\ 45^m$; wheel X, we have faid, has 62 teeth, one of which is impelled every 24 hours, therefore an entire revolution of this wheel, if the motion were continued, would be performed in 62 days; but it will be feen by and bye, that it never is permitted to make more than one half of a revolution, and frequently not fo much, before it is made to retrograde at one jump to its original fituation, from which it had been moved by the fingle tooth or pallet at V. Into the plane of the annual wheel A, are inferted 12 pins, at fuch diftances from each other, in a concentric circle, as are determined by the number of days in the correfponding months, which are fuppofed to lie refpectively between the faid pins, fo as to regulate the interpofed fpaces. Thefe pins might be denominated the pins of January, February, &c. in fucceffion, as they follow one another at the regulated diftances of $\frac{31}{365}$, $\frac{28}{365}$, &c. On the centre of the faid annual wheel, is alfo fixed the centre of a piece of metal, B, fhaped by an oblong curve, continually varying its radius of curvature half round, and in a fimilar way back again, which curve is denominated the *equation* curve, from the office it has to perform, which we will recur to prefently. Round the centre 5 of the two wheels X and Z, is moveable the lever 5 6, with a claw at 6, and a tail 5 3, refting on a pin in the click 2 7 8, which click is moveable round a point at 7; a fecond lever 10, has alfo its tail refting by a pin at 3, on the tailpiece of the click, while its inclined end 10 falls in the way of the pins of the months in the annual wheel, by means of the preffure of a flender fpring near the centre of its motion. The effect produced by thefe levers and click may be thus defcribed; the pallet at V continues, by its daily motion, to gather up a tooth of X every 24 hours, and the click 2, fliding over the inclined fide of the contiguous tooth, lays hold of it when paft, and keeps it faft till the next day, when the fame operation is repeated, the two levers in the mean time remaining quiefcent; this daily procefs goes on till one of the month pins of the annual wheel, meeting with the end of the lever 10, depreffes it; at the time this occurrence takes place, the tail of this lever pufhes, by means of its pin of contact, the tail 3 of the click back, and with it the fang of the click, which now quits the tooth it before held; the wheel X being now detached from the click and pallet V, and having a piece of watch main-fpring coiled round its centre, one end attached to it and the other to a ftud, is pulled fuddenly back to the fituation in which it was before it was gathered up by the pallet; and the hand D, *fig.* 2, being connected with this wheel, returns with it and recommences its motion from the beginning of the graduations of the double femicircle A B C, which is divided on the middle line, but figured alternately above and below, to prevent the figures from being crowded. The femicircle at D in *fig.* 2, is divided into $29\frac{1}{2}$ equal fpaces; and a portion of the dial is cut away, as reprefented by the dark portion, and full phafe of the moon, which conftitute a portion of the front face of wheel Z, of 90 teeth, which wheel we have faid revolves half round in $29^d\ 12^h\ 45^m$; this dark lunar plate has a mark as an index over the moon, which difappears the moment that a fimilar one at the oppofite point of the plate's circumference begins to appear; alfo another moon, at prefent hid from fight, begins to appear at one day's fpace of her age, as foon as the prefent one difappears at the fpace $29\frac{1}{2}$, and fo on alternately throughout the year. The graduations of the moon's age are on the principal dial. The anterior plane of the annual wheel has the fun's place in the ecliptic, the months, with their divifions into days, and fun's rifing and fetting in time correfponding to each day, marked on it, which readings appear through the blackened apertures of the dial, above the double femicircle of the days indicated by the hand D, and under the hours and minutes of the large circle, as reprefented in *fig.* 2.

When the wheel X, in *fig.* 1, has returned to its original fituation, the pallet at V goes on, and when it has made half of a revolution it meets with the end of the lever 6, and preffing againft it, difengages the tail 3 from the click 2, which prevented this click from falling into a notch of the wheel X, while this wheel retrograded; but now the click refumes its office, and the wheel of the months proceeds by a daily progrefs of one tooth: in the prefent fituation of the different hands and of the annual wheel, the day is the 5th of November, the moon's age almoft 15, being full moon, the fun-rife, $7^h\ 5^m$, A. M. fun-fet, $4^h\ 54^m$, P. M. and the fun's place 12° in Scorpio. The annual wheel, we have feen, revolves in $365\frac{1}{4}$ days exactly, therefore the fractional portion of a day will amount to unity every fourth year, and will require that February fhould have 29 days in each leap year; a provifion is here made for effecting this purpofe which fhews confiderable ingenuity; a piece of brafs of the fhape of 15 16 17 18, reprefented by dots chiefly, becaufe nearly hid behind the annual wheel, as now viewed in *fig.* 1, is moveable on the point 15, and has marked on the concealed flat part the 4 years fucceffively, *viz.* leap year, and 1, 2, and 3, after, which are brought annually in fucceffion to the aperture of the dial above VI. in *fig.* 2, by the annual wheel: the procefs is thus; the ftar 20 with eight angular points, has two of its points carried forwards by pins in the annual wheel, one of which acts on the night of the laft day of December, and the other in ordinary years at the end of the 28th of February; the ftar has a metallic leg, called by the French *un fautoir*, preffed by a flender fpring in fuch a way, that the heel falls into a notch of the ftar, the ufe of which is, to limit the quantity the ftar fhall move if it is moved at all; for when any following point of the ftar forces the leg forwards till it paffes the heel, the fpring then pufhes the heel in again, and forces the faid point forwards a little farther, till it ftops under the foot, and till the next following point of the ftar refts againft the back part of the leg where the motion is arrefted: a fnail with four fteps is faft to the ftar, and regulates the pofition of the piece 15 16 17 18 by fupporting the end 18 of this piece, which projects towards the fnail; hence it is eafy to apprehend, that numbers 1, 2, 3, or leap year, will appear in the aperture of the dial, accordingly as ftep 1, ftep 2, &c. of the fnail is prefented to the refting point 18 of the plate with the four years marked on its anterior face. This contrivance, however, does not yet account for the 29th of February every fourth year: the additional mechanifm for this purpofe is the rack without teeth, marked 11, moveable on the centre of the annual wheel, but under it in *fig.* 1, with a concealed fpring (dotted) preffing againft its concealed and dotted bar, fo as to make it reft on a fecond fnail behind the ftar; for as the lever 10 for the monthly pins is carried by this rack, the faid lever may be made to meet the pins or recede from them, or any one of them, the quantity correfponding to a day, or more if it were required; thus the concealed fnail, which has a contrary fpiral, removes the pin anfwering to the laft day of February fo far from the correfponding

ponding pin in the annual wheel, that the hand D, in *fig.* 2, has arrived at the 29th division or day-space, before the click is detached by the lever 10, and thus February has 29 days every fourth year. It may be proper to obferve here, that the fourth ftep of the fnail feen on the ftar has an inclined plane to allow the end 18 of the four years plate to afcend it without being fet faft, after a revolution has been completed. Hitherto we have faid nothing about the equation portion ufually but improperly defcribed firft, which we have deferred becaufe it depends on the motion of the annual wheel. On the point D, in *fig.* 1, the rack, E, moves, while its tail, C, refts on the circumference of the equation curve, as it makes its annual revolution; at O is a fmall box with a fpring, which keeps the cord 15 always ftretched; this cord furrounds a pulley on the plane of a concealed wheel N, under K, but not attached to it, with which wheel, N, the rack acts and is kept always refting on the equation curve in every fituation of the annual wheel; the pinion, I, revolves by the going part of the clock in 60 minutes, and carries the equable hand of the minutes, now pointing to 46 minutes in *fig.* 2; by the pinion I, which has 30 leaves, the wheel K of 60 teeth is driven; which in its turn drives another pinion, L, of 30 leaves; fo that L revolves in an hour as though it acted immediately with I; to L is attached a wheel, H, of 48 teeth, which actuates a fimilar wheel, F, and this again a third fimilar wheel, G, the tube of which furrounds the arbor of I, and carries the hand with a little fun on its pointing to 30^m in the dial, *fig.* 2, which hand moves irregularly, and may be called the *equation hand;* its irregularity is thus produced; the wheel N, below K, is pinned to a bar which is not feen, but which bears the wheel H, and pinion L; and as the teeth of the rack are acting with the wheel N, the concealed bar, here fpoken of, is made to move alternately towards I and 15, as the radius of the equation varies during the year; this motion of the bearing bar makes the pinion L fometimes advance, and fometimes retrograde a few teeth, independently of the motion it receives from the revolution of K, and this additional motion, produced by the rack to the bar on which L refts, is alfo communicated to the wheel H in confequence of its connection with L, and hence to both the fimilar wheels connected with it, F and G, the latter of which gives the faid addition and retrogradation alternately to the equation hand borne by it. The motion conftituting the equation, here fpoken of, would be produced if the wheel K did not revolve at all, and therefore is derived entirely from the equation curve, which curve has its fhape afcertained from a table of the equation of time. In the pofition of the two minute hands the diftance between them is 16^m, which is the quantity of equation fubtractive at the end of the firft week of November. The pinion of fix or eight leaves attached to F, drives the hour wheel of 72 or 96 teeth not given here, which bears on its tube the hour hand pointing between II. and III. which hand therefore participates of the equated motion, and correfponds to the equation minute hand; the minute hand for mean time is ufed to fhew, by its diftance from the other hand, the quantity of the equation at any given time. The feconds are for mean time, and therefore correfpond with the minute hand of mean time. Between the fmall wheel Q, which we have feen revolves in 24 hours, and the dial, is a fmall circular dial-plate feen through an aperture below 40^m in *fig.* 2, the ufe of which is, to regulate the annual wheel, by a key inferted in the hole at 40^m on the fquare of the arbor of the wheel Q, agreeably to the hour of the day indicated by the clock, otherwife the monthly pins might not happen to detach the click of the ratchet-wheel that carries the month hand, D, at the exact termination of the month. Laftly, between the wheels I and G, is placed a fmall fpiral fpring, to prevent a fhake in the hand carried by G, which the play in the teeth might otherwife have occafioned. This mechanifm, as we have faid, is very ingenious, and moft of the other equation clocks have a fimilar equation curve, without an allowance for leap year.

We have recently underftood that Quare, of London, was the firft inventor of an equation clock, but we do not vouch for our authority.

An Aftronomical Clock, by Mr. Thos. Reid of Edinburgh.

It has been ufual, among horological writers, to call all thofe clocks indifcriminately *aftronomical*, which are ufed in obfervatories for afcertaining the right afcenfions of the ftars, whether the time indicated is folar or fidereal, and alfo thofe clocks which reprefent the motions of fome or all of the heavenly bodies, by appropriate wheel-work fuperadded to the ufual train: thefe two kinds of clocks, however, are of a very oppofite nature, one of them rejecting every appendage that does not contribute to accuracy in the meafurement of time, under all the changes of atmofpheric temperature, and the other being loaded with cumberfome additional mechanifm, calculated to produce great irregularities of motion in the going train, befides being deftitute of compenfation mechanifm for the effects of heat and cold. They are, indeed, equally the produce of much ingenuity; but one is contrived and executed with the greateft care for ufe, while the other is defigned, calculated, and conftructed for mere curiofity: one is as fuperior in its meafurement of time to a common clock, as a chronometer is to an ordinary watch; but the other may be confidered, in general, as holding a rank, in this refpect, as much below a common clock: we feel ourfelves, therefore, juftified in giving diftinguifhing names to two machines, which, however they may be claffed in one genus, are of very different fpecies; the clock which is ufed in aftronomical obfervations we fhall call an *aftronomical* clock; but the clock which exhibits the relative pofitions of the heavenly bodies, or of any of them, we fhall call a *planetary* clock; of which kind is that which we have partially defcribed as being in the palace at Hampton Court, and of which kind are moft of Mr. J. Ferguson's more complex clocks. Sometimes clocks are made on the principle to which we propofe to give the appellation of aftronomical, which yet are not ufed in obfervatories, but kept at the clock-makers, with the view of being made a ftandard by which to judge of the rate of other clocks and watches not yet brought to time; thefe are ufually denominated regulators, but when they have good compenfating pendulums and the beft efcapements, they differ not from aftronomical clocks in any thing but the name, which is borrowed from the ufe to which they are put of regulating the time by which the common clocks are to have their rate of going adjufted.

We might have prefented the public with a great variety of aftronomical clocks, each differing from the others in fome particular peculiar to itfelf; but if we give the defcriptions of a couple, all the other conftructions, or the greateft part of them, will be eafily apprehended from our articles ESCAPEMENT and PENDULUM, which are as much the characteriftic parts of an aftronomical clock, as the efcapement and balance are of a chronometer, which machine has been already defcribed.

Plate XXII. of *Horology*, exhibits, in different points of view, an aftronomical clock, made by Mr. Thomas Reid, of Edinburgh, of which his brother, who refides in Clerkenwell, London, obligingly permitted our draftfman to take the requifite drawings for rendering all the effential parts intelligible. *Fig.* 1, is a view of the movement, with the eye placed perpendicularly over it, and the front plate of the

 frame

frame taken off; and *fig.* 2, is the whole frame detached from the cafe and viewed laterally, which pofition may be confidered as a fection, the other being the plan of the works; thefe two figures are laid down on a fcale of one third of the original fize; *fig.* 3, is an enlarged reprefentation of the pallets and efcapement wheel, on a fcale of one half the real fize, and in a detached ftate; *fig.* 4, fhows the back of the great wheel of 120 teeth, together with the fmall ratchet and auxiliary fpring and detent in a detached ftate, of one third the real fize; *fig.* 5, exhibits the gridiron, or compenfating pendulum, with its cock and other parts of fufpenfion, of one eighth part of the real fize; and *fig.* 6, gives an enlarged view of the part that receives the crutch immediately above the fuperior end of the gridiron portion of the pendulum; we fhall defcribe thefe fix figures in the order by which we have here enumerated them.

A A, in *figs.* 1 and 2, ftand at the fuperior end of the frame plates, above the pillars, which are omitted in the fecond figure, that the efcapement wheel may not be concealed thereby; B, in both figures, is the cylindrical barrel for the cord C, of the weight, which conftitutes the maintaining power; the wheels and pinions are denoted by the numbers of their teeth thus; 120 is the great wheel revolving in twelve hours; 10 is the pinion driven by it on the central arbor; the fmalleft, 96, is the centre wheel; 12, the pinion on the fecond wheel-arbor, which arbor has alfo the fecond wheel of the train, marked 90, impelling another pinion of 12 on the arbor of the third or efcapement wheel of 30 teeth; the other two wheels of 96 each, revolving alike in 12 hours, are inftead of dial-work. The fmall ratchet wheel has 40 teeth, and the large one or perpetual ratchet 200, that the teeth of its circumference may be numerous enough to catch the detent G, *figs.* 1 and 4, without allowing the intenfity of the auxiliary fpring, H, to be remitted; but the exact number of teeth is of no importance, provided they be both numerous and ftrong enough to anfwer the defired purpofe; the number is here mentioned to fhow that the wheel has been cut in an engine which divided it into 200 equal ferrated teeth. The fpring, which is here a fubftitute for the maintaining power, during the time of winding up the clock, has its extreme ends brought nearer together than was the cafe with the auxiliary fpring of the chronometers which we have above defcribed, but the office performed is precifely the fame, the only difference is in the mode of application; here one end of the auxiliary fpring is attached to the great wheel, and the other preffing againft the fide of one of the croffes of the great ratchet, or perpetual ratchet, and when the two ends of the fpring are brought nearly together, their effort to feparate becomes a temporary fubftitute for the maintaining power. The hour hand revolves in 12 hours along with the arbor of the great wheel of 120 teeth, on which it is placed by fimple friction without a fquare; the long hand E, *fig.* 2, fhows minutes from the arbor of the centre wheel, on a circle of 60 furrounding all the hands; and the third hand F, fhows feconds on the arbor of the pallet wheel; this hand has a very fmall recoil on account of the faces of the pallets not being portions of concentric circles. The pallets have each a piece of agate to fuperfede the ufe of oil, and are of the ifochronal kind, acting with teeth of a peculiar fhape, both of which will be more particularly defcribed under the article ESCAPEMENT: the two agates are retained in the hollow parts of the anchor of the pallets by three fcrews applying to each, two of which are vifible in each pallet in the enlarged *fig.* 3; and the two vertical lines below the wheel of this figure reprefent, one of them, the pofition of the pendulum correfponding to the prefent fituation of the pallets; and the other, which is drawn a little afide, the fituation of the fame at the inftant of efcaping; which with other particulars of this efcapement will be more minutely detailed hereafter, according to our recent reference. The frame is mounted by four pillars, fituated near the four corners of the two plates, at the fmall circles in *fig.* 1; and is firmly attached to the bracket or bearing piece L, *fig.* 2, at the fuperior part of the cafe, by the connecting cocks, K and K, fcrewed both to the frame and piece L. Though there is no dial-work in this clock, yet there are four little cocks, *a*, *b*, *c*, and *d*, on the front plate of the frame, the ufe of which is to make the wheels and pinions fall as nearly as can be at the middle of their refpective arbors, fo that there may not be more preffure at one pivot than at the oppofite one of any arbor; a refinement which few other makers have attended to in their conftructions. The French clock-makers have given an appropriate name to each end of the arbor, depending on the diftance of the pivot from the wheel it bears, one end being called the *tige*, and the other the *tigeron*. The author of this conftruction attaches, and very properly, fome importance to the pofition in which the great wheel and cord of fufpenfion are placed, with refpect to the centre pinion; it may be feen from an infpection of *fig.* 1, that the weight fufpended by the cord C, refting on the acting tooth of the great wheel, does not prefs fo much on the pivots as it would do if placed at the oppofite fide of the barrel: for in one cafe the preffure on the pivots may be faid to be halved, but in the other doubled; fuppofing the barrel and wheel to be to each other as 1 : 2; befides, an uniformity of appearance is thus preferved in the three circles of the dial, which, we have not before faid, is attached to the frame by pillars, two of which are feen in *fig.* 2, at *e* and *f*.

The pivots of all the arbors are made cylindrical, and act in conical holes in the cocks before, and in the plate behind, which holes have the fmaller ends continued through the metal, at the back faces of which is prefented the conical point of a piece of fteel, to each fixed to the cock in fuch a way, that a drop of fine oil lies between it and the pivot, detained by its cohefive attraction in the form of a fpherule: this contrivance keeps the oil in its place better than counterfunk holes would do, and preferves it from impurities longer; the fteel pieces at the pivots entering the pillar plate, are feen at *g*, *h*, and *i*.

Fig. 4, requires no further explanation than we have given of the great wheel and perpetual ratchet in *fig.* 1, except that the under-fide is here prefented to view, and that the fame letters of reference apply to both figures. *Fig.* 5, is a reprefentation of the gridiron pendulum, which we have faid was invented by J. Harrifon; the dimenfions in the drawing are on a fcale of one eighth of the real fize of all the parts. The two obtufe angled cocks, *a* and *a*, braced with crofs pieces near the top are firmly attached to the bearing part or bracket, L, in *fig.* 1, which has a portion taken out between L and L, in *fig.* 5, for the pendulum to vibrate in, but which cannot be feen in the pofition in *fig.* 1, where the cocks are on a larger fcale, and where one of them is hid by the other, which appears as a ftraight vertical piece of metal above M; which M denotes the edge of the pendulum in this figure: on the fuperior ends of the two cocks is made an angular notch called a Y, the top of which it refembles, in which the pivots of a tranverfe piece of fteel, *b*, reft; this tranfverfe piece has a central fquare hole that receives a little rod by which the pendulum is fufpended by a flip of watch main-fpring, tapered a little downwards; the three pins, one above the tranfverfe piece, *b*, and the other two at the oppofite ends of the flip of fpring, may all be feen in the figure without more particular reference; the rod attached to the upper end of the gridiron is of fteel, and has an oblong hole

hole with a pair of agates fixed in it, ſo as to form the ſides of the oblong hole, ſeen on a larger ſcale in a detached ſtate in *fig.* 6; the uſe of this long aperture is to receive the pin of the crutch, carried by the arbor of the pallets, as ſeen at N, in *fig.* 2. By this method of ſuſpending a pendulum, the ball has liberty to find its own perpendicular ſituation without twiſting the ſlender ſpring of ſuſpenſion, and the tranſverſe piece, *b*, having ſhoulders to keep it ſteady within the frame compoſed of the cocks, *a* and *a*, prevents any motion or ſhake that might otherwiſe be occaſioned by the vibrations of a heavy pendulum; alſo the pendulum may be put into exact beat, by forming the ſhoulders of the tranſverſe piece, *b*, ſo exactly at each ſide of the centre, that the crutch may not require to be bent; and if a ſlight deviation from true beat be obſerved when the cocks are mounted *pro tempore*, a ſlight lateral motion in them, before final fixing, will rectify the beat; or the poſition of the agates of the crutch pin might be reſorted to for adjuſting a very minute deviation from true beat; or, laſtly, an adjuſtment of the bearing part, L, might be recurred to; but we think it is of importance not to alter the central ſituation of the oblong aperture where the crutch-pin acts, leſt this pin ſhould not impreſs its force to a point perpendicularly over the centre of gravity of the pendulum, and ſhould thereby produce a vacillation in the vibrations, which would be injurious to the exactitude of their obedience to the laws of gravity. The compenſation for heat and cold, and adjuſtments for time and temperature of this gridiron pendulum, may be explained thus; as we have not room to put in the letters of reference between the bars of the gridiron portion, we propoſe to call the rod attached to the ſpring of ſuſpenſion 1, which is the middle rod of the nine parallel ones; the two contiguous rods, one at each ſide of N°. 1, we ſhall deſignate by the figures 2 and 2, reſpectively; the two next in order to the right and left from N°. 1, we ſhall call 3 and 3; in like manner the two next at each ſide, correſponding to each other, we ſhall name 4 and 4; and the two extreme ones, 5 and 5, reſpectively; this mode of deſcription will ſhorten the circumlocution we muſt otherwiſe have been obliged to uſe: N°. 1, we have already ſaid, is a ſteel rod proceeding downwards from the point of ſuſpenſion; it has a ſhort croſs-piece, to which are faſtened the inferior ends of the rods, 2 and 2, which are of braſs, and conſequently more expanſible than ſteel; theſe rods, which may be conſidered as one ſo far as relates to their expanſion, proceed upwards to another croſs-piece ſomewhat longer than the firſt, to which their upper ends are faſtened: again another pair of rods, 3 and 3, of ſteel are faſtened to this ſecond croſs-piece near its extremities, ſo as to include the three former rods, and deſcend down paſt the ends of the firſt croſs-piece into a third croſs-piece, below the firſt, to which third piece they are united: this third piece alſo ſupports another pair of braſs rods, 4 and 4, which aſcend to the uppermoſt or fourth croſs-piece of the gridiron, to which they are alſo attached; and, laſtly, another pair of ſteel rods attached to the extreme ends of this fourth croſs-piece, ſo as to include all the former ones, deſcend to the loweſt or fifth croſs-piece, to which they are attached, and by which the gridiron frame is completed. The effect of the expanſion of the deſcending rod, 1, is to lower the firſt croſs-piece; but the effect of the expanſion of the two aſcending rods, 2 and 2, is to elevate the ſecond croſs-piece more; the effect produced by the pair, 3 and 3, as this effect relates to the third croſs-piece, is ſimilar to the effect of rod 1, on the firſt croſs-piece; alſo the effect of the pair of braſs rods, 4 and 4, on the fourth croſs-piece, is ſimilar to that of bar 2 and 2, on the ſecond croſs-piece; and, laſtly, the effect of the pair, 5 and 5, of ſteel bars on the height of the fifth or laſt croſs-piece, is analogous to the effect produced by the pair, 3 and 3, on the third croſs-piece, as above deſcribed: the total effects of the deſcending and aſcending bars are ſtated to be thus in the clock before us: *viz.*

Expanſion downwards by rod 1, =	1
Do. - - by rods 3 and 3, =	1
Do. - - by rods 5 and 5, =	1
Total =	3
Expanſion upwards by rods 2 and 2, =	1.56
Do. - - by rods 4 and 4, =	1.56
Total =	3.12

Hence the difference between the total elevation and total depreſſion of the ball, which is ſuſpended by the loweſt croſs-piece, is $\frac{12}{100}$ which quantity of exceſs of the aſcending bars is taken as an equivalent for the downward expanſion of the ſpring of ſuſpenſion, and that part of the ſteel rod, 1, which is above the gridiron portion; and if this quantity on trial ſhould be found to be an exact balance, the compenſation of the pendulum will be perfect, and the centre of oſcillation of the whole pendulum will continue unchanged as it regards the point of ſuſpenſion under all the variations of temperature. Whenever it is found that the calculation for the reſpective lengths of the expanſion bars has been erroneous, or the materials imperfect, the adjuſtment for temperature muſt be made by altering the ſituation of the firſt croſs-piece, ſo as to lengthen or ſhorten the pair of braſs bars, 2 and 2, as they regard the ſteel bar 1; it is better to make the braſs ſomewhat too long than too ſhort for the ſteel bars, becauſe this croſs-piece can be raiſed when it cannot be lowered beyond a certain limit depending on the proximity of the third croſs-piece; and if that limit ſhould be found too circumſcribed, the croſs-piece above, which has four bars faſt to it, muſt neceſſarily be lowered, which will be attended with ſome trouble.

The adjuſtment for time is made by means of a nut with a milled head, under the ball of the pendulum, the ſocket of which nut, is tapped to ſuit the thread of the ſhort rod attached to the loweſt croſs-piece of the gridiron frame by which the ball is borne, ſo that the ball reſts not with its inferior edge on the nut itſelf as in ordinary clocks, but has a pin in its centre which reſts on the upper end of the nut's ſocket, and which ſlides in a ſlit made in the bearing rod above and below, as well as at the centre of the ball for the ſake of allowing an aſcending and deſcending motion of the inſerted pin borne by the central hole of the ball. The uſe of this contrivance is to prevent any effect on the pendulum produced in general by the upward expanſion of the ball itſelf, for the ball being circular, will in this caſe expand from the bearing pin in the centre, alike upwards and downwards, as well as in a lateral direction to the right and left. Strictly ſpeaking, however, the bearing pin to have its true ſituation for preventing all effect from the expanſion of a large ball, ought to be placed in ſuch a ſituation as ſhall have a regard to the centre of oſcillation of the pendulum conjointly with the weight and dimenſions of the ball, which, in ſo complex a pendulum, conſtitutes a difficult problem to ſolve in all the variety of caſes likely to ariſe in practice.

This pendulum has a weight of 9 pounds, and the clock goes eight days with a weight of $16\frac{1}{2}$ pounds, falling 4 feet 10 inches in this ſpace of time.

We

We are informed by Mr. Reid's brother, that the arc of escapement in each excursion is two degrees, and that the remaining portion of the said excursion is one degree; hence the whole arc of vibration is just 6° with the weight already mentioned. The peculiar property of this escapement, as will be seen in another place, is, that whatever be the maintaining power, or the total arc of vibration, the partial recoil which it has renders all the vibrations isochronal.

It is scarcely necessary to add, that an astronomical clock, like a chronometer, ought to have all its adjustments made with great care, in order that some dependence may be placed on its rate of going under all circumstances.

An astronomical Clock, with Troughton's Pendulum.

Each astronomical clock has usually some part or parts peculiar to itself; the clock, which we are now about to describe, differs from the preceding one in various particulars, but principally in the structure of its escapement, pendulum, suspension, and pivot holes. *Plate* XXIII. explains the works, and *Plate* XXVII. the pendulum and suspension of the clock before us: we will first describe *Plate* XXIII. *Fig.* 1, is a view of the movement, with the front plate removed, and the eye perpendicularly over the centre, which therefore may be called the plan of the movement; *fig.* 2, is a section, or side view of the frame, containing the movement, a part of the suspension and pendulum, and the dial-work, face, and hands; *fig.* 3, is a front view of the front plate of the frame, as seen with the hands and dial off; and *fig.* 4, is the escapement-wheel and pallets of the dead beat kind. In *figs.* 1 and 2, A is the great wheel with 120 teeth, and a perpetual ratchet of the same number of teeth, similar to the one described in the going fusee of Brockbank's chronometer, which great wheel impels the centre pinion, *a*, of twelve leaves in an hour; the arbor of this pinion carries the minute hand, or large hand seen in *fig.* 3, moving from the centre of the dial; B is the centre-wheel, of 96 teeth, on the same arbor, drivingthe pinion, *b*, of 12 leaves; and C is the second wheel of the train, with 90 teeth, urging the pinion *c*, of 12 leaves, on the arbor of the pallet or escapement-wheel D, which, as usual, has 30 teeth; this wheel revolves in $\frac{12}{96} \times \frac{12}{90}$ of an hour, which is exactly one minute, and therefore carries the hand of the seconds, or small hand, seen in *fig.* 3, above the minute hand. For a particular account of the dead-beat escapement, we beg leave to refer to the article ESCAPEMENT, a description of which in this place would lead us out of our purpose; *e* and *f* are two cocks on the pillar-plate or back plate, into which the arbor, *g*, of the guard-gut, *h*, is pivoted; and *i* is the spring of the guard: below D, in *fig.* 2, is the arbor of the detent of the perpetual ratchet; and below *g* in the same figure is the arbor of the small dial-plate, and its wheel *k*, seen on the frame in *fig.* 3, by a front view; this wheel has 192 teeth, and borrows its motion from a pinion of 8 leaves on the arbor of the centre wheel, these numbers of teeth being to each other as 24 to 1; they are the only dial-work this clock has got; the dial-wheel might have had a hand like the centre wheel, but it would have had its motion retrograde, on which account a light plate, equally poised, and neatly engraved, is put on behind the principal dial instead of it, and the hours are read through a circular aperture made in the large dial, and a fleur-de-lis on the front of this large dial serves as a stationary hand for indicating the hour on the revolving plate, which makes a revolution in a day. At *l*, on the arbor of the centre wheel, behind the dial, is a lever for counterpoising the minute hand, which, being long, of course has a sensible weight, that would act alternately with and against the maintaining power as reduced at this arbor, if there were no such counterpoise. The four black circles, at the four corners of *fig.* 1, are the four pillars pointing to the eye, and near the centre wheel is the fifth; their corresponding outer ends are seen in similar situations, with their fastening screws in *fig.* 3; the other four black circles, within the pillars in *fig.* 3, are the holes for receiving the pillars of the large dial, or face of the clock, two of which pilars, *m* and *n*, are seen in *fig.* 2, and also the edge of the dial *o p*. The frame is screwed to E, the bearing part of the case, by two screws passing through this piece and entering the lower pillars of the frame, one of which screws is seen in *fig.* 2, at F, and the other is on the opposite side. The pivots of the pallet's verge, of the pallet-wheel arbor, and of the second-wheel arbor, all run in jewelled holes in the small cocks, 1, 2, and 3, respectively in *figs.* 2 and 3, and the piece 4, in *fig.* 3, covers the end of the detent-arbor pivot. This clock, which was made by the Brockbanks, and which is the property of Mr. Ed. Troughton, is finished in a very superior stile of workmanship; and though for many years it has been regulated by a pendulum composed of a glass tube and bulb containing quicksilver, which was Troughton's improvement on Graham's quicksilver pendulum, yet its performance has at least equalled, if not surpassed, in accuracy and steadiness of rate, the going of any other clock that has been constructed; if we may credit the report of an individual every way qualified to judge not only of its absolute but comparative excellence: the pendulum, however, which is here made a part of this clock, is of recent invention, and we have great reason to believe will shortly supersede all the other compensation pendulums that have preceded it, on account of its possessing the following properties almost exclusively: first, it has all the advantages of opposite expansions which the common gridiron pendulum possesses; secondly, the arrangement of the metallic parts gives it the simplicity in appearance of a single rod, as well as a diminished resistance of the air in its vibrations; thirdly, it has great strength without much weight above the ball; fourthly, its centre of oscillation, compared with the centre of the ball, or with the centre of gravity, may consequently be very nearly determined; fifthly, the motions of the compensating parts upwards and downwards are not effected by jerks, but are progressive and steady, while yet the parts are sufficiently braced to preserve their relative situations and figures; sixthly, the compensation not only includes the spring of suspension, and is adjustable for temperature, but has its adjustment for temperature made, independently of the rate of going, by a new pyrometer of great sensibility, and free from the usual objections against pyrometers; seventhly, it is capable of being put into beat without altering the shape of the crutch, or of any other part; and, lastly, it is capable of adjustment for rate even while going. It would have been more consistent with our general plan to have given an account of the pendulum in question under the word PENDULUM, but as that article is a remote one, the reader will doubtless have no objection to have the description here. The common gridiron pendulum has already been described in our preceding section, and its mode of compensation explained; therefore we need not use much circumlocution in our present detail. *Fig.* 1, of *Plate* XXVII. of *Horology*, shews a front view of the pendulum as suspended by a board or plug attached to a solid wall; and *fig.* 2 is a side view of the same: *fig.* 3, which represents pretty nearly the common gridiron pendulum, is a representation of the compound part of the pendulum with the rods placed to the right and left of the central one, for the sake of being all seen, instead of being arranged round it, as they ought to be agreeably to the circular section below, which is the true arrangement, but which is not so easy to be apprehended by mere verbal

verbal defcription, as we prefume it will be from the prefent, though unnatural, figure. The middle rod, reaching to the fufpenfion, is of fteel, which, as before, we will call 1, defcending to the crofs-piece *a*, which is a circular plate perforated with a central and four other holes, as feen in the fubjoined fection; under the central hole of this circular piece the rod 1 is pinned; then inftead of a pair of brafs rods afcending contiguous to, and at each fide of, this central fteel rod, as ufual, a brafs tube has its lower extremity faft to the circumference of this fmall plate *a*, and afcends within a fecond larger tube to another fimilar circular plate *b*, with five holes likewife, to which it is attached in like manner; the two brafs tubes are fo clofe together, that they appear as one, except that the inner one is darker than the other in the figure; to the plate *b*, above the afcending inner brafs tube, are faftened two fteel rods, which we will here denominate 2 and 2, appearing contiguous to the rod 1 in the figure, but actually at the fame diftance as the next pair denominated 3 and 3, which pairs ftand at right angles to one another, as feen in the fection under the figure; the pair of fteel rods, 2 and 2, having defcended from *b*, pafs through a pair of the holes of *a*, and are pinned under a tranfverfe circular piece, *c*, that has only four holes in it; to the circumference of this piece, *c*, is made faft the outer brafs tube that hides all the rods and other tube, and that afcends to a fourth circular piece, *d*, which forms an end-piece to the large tube, to which it is fcrewed faft; laftly, the pair of fteel rods, 3 and 3, are made faft to the end-piece *d*, and defcend through the other pair of holes of the three pieces, *b*, *a*, *c*, to a fifth crofs-piece, *e*, under which it is pinned, and by the central hole of which the ball of the pendulum is hung at its centre, or nearly fo. This fubftitution of two brafs tubes for four brafs rods, together with their end-pieces, and the mode of arranging the fine fteel rods within the tubes, afford all the properties united which we have previoufly mentioned; and it is eafy to fee that fhortening either the rods of fteel, or the brafs tubes, will alter the ratio of the refpective aggregates of their length, fo as to increafe or diminifh the effect of the oppofite expanfions, till they exactly balance one another, when a delicate and very exact meafure is taken from the point of fufpenfion to the centre of ofcillation: this meafure is taken with great eafe and accuracy by the new pyrometer which we have feen ufed, but which has not yet been publicly defcribed, and the principle of which we do not feel ourfelves at prefent authorifed to announce; when the author has gone through all his pyrometrical experiments, moft probably he will lay before the public the conftruction and the experiments at prefent in hand, both of which, no doubt, will prove interefting. Indeed we can now venture to refer the reader to our article PYROMETER for the information we have fpoken of, prefuming upon the experienced liberality of the author. Above the end-piece, *d*, of the outer brafs tube is a fmall tube of the fame metal furrounding the fteel rod that afcends to the fufpenfion fpring, the ufe of which is to receive the fork of the crutch and to guard the fteel from the oxiding influence of the air, as well as, it is probable, the other rods will be preferved, by being enclofed in the brafs tubes. If we can difcover any thing like the fhadow of an objection to this ftructure of the compenfation-pendulum, it is, that the included fteel rods not being expofed to the air, may not be fo foon affected by atmofpheric changes of temperature as the brafs tubes; but we can hardly perfuade ourfelves that the difference will ever be fo fenfible as to affect the rate of going of the clock, feeing all the parts are very contiguous to one another throughout the whole length, and muft confequently affect one another's temperature, by that general contiguity, at all times.

Figs. 4, 5, and 7, are views of detached parts of the fufpenfion, and *figs*. 8 and 9 of the crutch, all which we come now to explain, as effential appendages of the pendulum. We have already faid, that E, in *fig*. 2, *Plate* XXIII. is the bracket on which the frame is fixed; to this bracket the brafs triangular frame G is fcrewed faft, different views of which may be feen in *figs*. 1, 2, and 5, of *Plate* XXVII., as well as in *fig*. 2, *Plate* XXIII., in the laft of which the fcale is larger than the others: at the top of this frame is a milled nut, and under it a micrometer head, *a*, in *figs*. 1, 2, and 3, of *Plate* XXVII., with 22 divifions on the circumference of the micrometer head to fuit the finenefs of the threads of the fcrew, by which the adjuftment for rate is made; below the divided head is a fquare piece of metal, *c*, in *fig*. 4, which in *figs*. 1 and 2 is concealed within a tube having a fquare hole, feen at *c*, in *fig*. 5, feparately; to the fuperior end of this tube with a fquare hole is an index made faft, pointing to the divided head, feen alfo in *fig*. 5, which figure 5, is a detached view, on a larger fcale, of the part *b* in *fig*. 2; at the lower end of the fquare piece *c*, in *fig*. 4, is the piece of watch main-fpring, called the fpring of fufpenfion, to which the middle fteel rod of the pendulum is pinned; that part of the piece *c*, which receives the nut and divided head, being tapped, draws the pendulum up and down when the divided head refts on the frame G, and is turned in a proper direction; the cock *b*, with its tube *c*, is fhewn as detached from the frame G, in *fig*. 5, but the manner in which this cock is attached to the frame, may be feen from the fittings; the dove-tailed piece, *d*, when detached from the cock *b*, enters the dove-tail of the cock G from *d* behind, above G, before the faftening fcrews attach it to the cock *b*, while the cock refts on the fhoulder of the frame G. *Fig*. 7, is a front view of the cock *b*, in *fig*. 5, and is on an enlarged fcale, as compared with the fame in *fig*. 1; *b* in this *fig*. 7, is a thumb-fcrew, which draws the two pieces, *e* and *f*, together, between which the fufpenfion fpring is clamped, after the adjuftment for rate is finifhed; fo that in fact, the lower edge of thefe two clamping pieces, *e* and *f*, may be called the point of fufpenfion, as it relates to the diftance from the centre of ofcillation of the pendulum; and is, therefore, the point from which the effective length of the pendulum ought to be meafured; the fcrew over *e*, which holds this piece to the tube, *c*, is in an oblong hole which allows the piece, *e*, to move without the faid tube. *Fig*. 6, is a front view of the frame top, when *fig*. 7, is taken off, the piece, *d*, in the cock, as fhown in *fig*. 5, is here fhown in its place inferted into the oblong dove-tailed hole of the frame, G, together with the two fcrew-holes at each fide of the letter, *d*; when the cock in *fig*. 7, is placed fo as to cover the fliding-piece, *d*, in *fig*. 6, and is fcrewed faft to this piece by two fcrews from behind the frame, it is evident that, when one of the two lateral preffing-fcrews, *s* and *s*, is turned forward and the other back, the fliding-piece, *d*, and with it the whole cock in *fig*. 7, will move from right to left, or the contrary, as the cafe may be, and confequently the pendulum, borne by this cock, as in *fig*. 1, will have a lateral adjuftment, to bring the clock into exact beat without the rough treatment of bending the crutch, which is often done in other clocks; when the fcrews are all faft, however, the cock is as fteady, as though it had neither the vertical nor horizontal adjuftment; and as the pin at the lower end of the fquare piece, *c*, *fig*. 4, is fmaller than the hole in the upper end of the fufpenfion-fpring, the pendulum finds its own vertical pofition before it is clamped, as well as if it were to be fufpended by Y's and a horizontal axis, that admit not of adjuftment for rate while the clock is going. *Fig*. 8, is the crutch, attached by the fuperior end to the verge of the pallets,

pallets, as seen behind the frame, in *fig.* 2, of *Plate* XXIII. where its fork embraces the brass tube on the upper end of the pendulum, as seen in *fig.* 9, of our present plate; in Mr. Reid's clock, we have seen, a solid part of the fork entered an oblong hole in the pendulum, which hole was formed of two jewels to avoid friction; it may not appear to the reader at first why there should be friction in this hole; but if he considers that the bent end of the crutch moves in a portion of a circle of smaller radius than the perforated part of the pendulum does, he will perceive that the crutch-pin must necessarily ascend in this hole during the excursion of the pendulum, and the more, the further the pendulum swings; to avoid the ascent of the forked part of our present crutch, it is not firmly attached, as in general, to the lower end of the vertical part of the crutch, but the crutch is first bent into the form of an L reversed, when viewed as in the plate, and then a pin is inserted into the remote end, *a*, of the bent part to become a centre of motion for the lever of the fork, which has a small tube moving round the pin so as to keep it in the same plane always, as seen in *fig.* 9; in *fig.* 8, the curve of the fork is in the same plane, facing the eye, as its lever; by means of this contrivance the fork, which holds the top of the pendulum-rod fast, moves in the same radius of curvature with it, and though it rises and descends alternately, as it regards the point, *a*, round which it has an unrestrained motion, yet it continues to clasp the same part of the rod, and never slides from its hold, thereby avoiding all friction, except the insensible quantity at the point of motion, *a*. The ball of the pendulum is of the lenticular shape, but a little flattened at the circumference to allow it to hold more lead, and to be heavier than it otherwise would be. A small portion of a circle is attached to the frame below the ball of the pendulum, at 48 inches from the point of suspension, and a pointer demitted from the ball shows the number of tenths of an inch contained in the whole arc of vibration: this clock will go eight days, with a power of 3 lb. $1\frac{1}{2}$ oz. avoirdupois, falling six inches per day; its arc of escapement, on the scale, is 2.2 inches, and the total arc of vibration usually, when the clock is clean, 3.4 inches; which numbers may be converted into degrees and minutes, thus: the circumference of a circle, of 48 inches radius, is very nearly 151 inches; therefore say, as 151 in. : 360° :: 3.4 in. : 8° 6′, the whole arc of vibration; also as 151 in. : 360° :: 2.2 in. : 5° 14′, the whole arc of escapement; hence each whole excursion is 4° 3′, and each arc of action on the pallets in that excursion 2° 37′, in the clock before us: which quantities are to each other very nearly as 17 to 11. We do not profess to say that this is the best ratio to be adopted in practice between the arc of excursion and the arc of action on the pallets, because we believe that the experiments hitherto made on dead-beat escapements, to determine the best slopes of the faces of the pallets, have not been numerous enough to warrant a conclusion on this point, which, notwithstanding, we think of great importance, and recommend to the notice of clock-makers. Mr. Nicholson, the author of the "Journal of Philosophy," &c. once informed us, in conversation, that his seconds pendulum clock with a dead-beat escapement, having its curves nicely formed in a lathe, does not vary its daily rate more than a second per day, when the maintaining power is increased as much as four or five times, or more, which we believe, is not usually the case with dead-beat escapements; we are not, however, at present informed of the exact quantity of the arc of action on the pallets, on which most probably the isochronal property chiefly depends, though we were at the same time informed that the suspension-spring is tapered from the top downwards, in a way that aids the longer vibration by quickening them. The subject is worthy of minute investigation, particularly as Berthoud has asserted, that in his experiments he always found his clocks retard with the dead-beat escapement by the addition of weight to the maintaining power, and *vice-versâ*, which was his reason for contriving his isochronal pallets. The experimentalist, however, ought to bear in mind, that both the length of the arc of action and the modification of the impulse vary with the slope of the pallet's faces in the escapement in question.

Clock-*maker*. If we were to define the word clock-maker agreeably to the derivation of the term, we should simply say that it means a man who makes clocks, and this definition, at one period of the art, would have been sufficient for our purpose; but since clocks have become so common as to be considered as articles of household furniture, the art of making them has not been confined, as at first, to one department of mechanics, but has gradually ramified into various branches, so distinct from one another, that the maker of one part is frequently unacquainted with the operations requisite for the manipulations of another, equally essential. Since the time that clocks became an article of our manufactories, requiring various tools and engines for facilitating their construction, the subdivision of the art into various departments was a natural consequence, which has been found to contribute to expedition, and consequently to cheapness; and, for the same reason that a tailor has no need to understand either spinning, weaving, or dying, a finisher of a clock has now no occasion to cast or cut his wheels himself, much less to make his springs or enamel his dial-plate. From custom, however, that man is called a clock-maker, who finishes or puts together the different constituent parts of a clock when made, and who has his profit from the sale of the machine; though the makers, more properly speaking, are the workmen employed in making the frame and contained wheel-work. The different operations may, indeed, be most of them performed by one workman, when the construction is intended to be peculiar, or the works of superior accuracy, but in general the different departments of the art may be separately enumerated, agreeably to the subjoined order, *viz.*

1. The brass-founder casts the wheels, plates, pillars, and faces, according to approved models:
2. The spring-maker forges, shapes, and tempers the main-springs, to any required strength or dimensions:
3. The making of the weights, to be used as maintaining powers of the balls, or bobs, and hands, may be considered as one branch:
4. The man who keeps a cutting-engine and a fusee-engine, cuts the wheels and pinions, and forms the grooves on the fusee or barrel, accordingly as a spring or suspended weight is used as a maintaining power:
5. The movement-maker mounts the frame, makes the wheels, pinions, detents, &c. and places them in the frame, agreeably to the proposed calliper.
6. The clock-smith forges the steel pieces for the arbors, pinions, pallets, rack, hammer, detents, &c.:
7. The bell-founder casts the bell, or bells when the clock has chimes:
8. The enameller prepares the ground of the dial, or face, for receiving the colour of the figures, and gets the painter to lay on the figures, agreeably to the calliper, with or without a circle for the seconds:
9. When the face is not of real enamel, a japanner, or imitative enameller, prepares and finishes the dial:
10. When the face is brass silvered, an engraver usually prepares, and sometimes also silvers it:

11. A

11. A jeweller is employed for the pallets and pivot-holes of the beſt aſtronomical clocks and regulators :

12. The gilder is frequently employed for preparing the ornamental parts of the caſe :

13. The glazier is applied to for the door of the ſuperior part of the caſe, when a ſeconds pendulum is uſed, and for the principal door ſometimes, when the clock has a ſhort pendulum :

14. The cabinet maker is reſorted to, uſually, for the caſe of the clock ; and ſometimes alſo the carver :

15. The chain or cat-gut maker is indiſpenſably neceſſary :

16. Recently the tubular compenſation-pendulum has been made and adjuſted, by the mathematical inſtrument-maker, as being a portion that requires great preciſion :

17. Laſtly, the finiſher, or, as he is otherwiſe called, the *maker*, poliſhes the teeth and ſteel parts, finiſhes the pivots, verifies the engagement, adjuſts the eſcapement, limits the arc of vibration by adjuſting the maintaining power to the weight of the ball, regulates the adjuſtments for beat and rate, finiſhes the ſtriking and repeating parts, and puts the whole machine into a ſtate ready for ſale.

CLOCK-*makers, Company of.* See COMPANY.

CLOCK-*making.* Clock-making, or the art of making clocks, ſeems not to hold that rank among the mechanical arts, which its connection with the ſciences, particularly that of aſtronomy, and alſo which the many ingenious improvements it has undergone by the help of ſcientific men, entitle us to expect. The cuſtom of working by piece-meal from eſtabliſhed models, which, it muſt be allowed, contributes greatly to expedition and cheapneſs, has, no doubt, conduced to exclude calculations and geometrical principles from the workſhops of the preſent day : whence it ariſes, that if we wiſh to be introduced to the workman who has had the greateſt ſhare in the conſtruction of our beſt clocks. we muſt often ſubmit to be conducted up ſome narrow paſſage of our metropolis, and to mount into a dirty attic, where we find illiterate ingenuity cloſely employed in earning a mere pittance, compared with the price which is put on the finiſhed machine by the vender of more eaſy circumſtances, though the latter has had little more trouble in the conſtruction than to order his name to be inſerted before it is placed for public notice in his bow-window. The practical departments of this art being thus frequently confined to the obſcurity of a garret, it is no wonder that a dexterity at performing certain manual operations, ſuch as hammering, filing, drilling, turning, ſoldering, tempering, poliſhing, &c. ſhould be conſidered as the perfection of the art, and that the reaſon is frequently not underſtood by the workman himſelf, and ſeldom by his employer, why the numbers of his wheels and pinions, and the ſhape, ſize, and diſpoſition of the different portions of his mechaniſm, are deemed preferable to others which he might have adopted as eaſily, if, in his apprenticeſhip, he had been ſo inſtructed. Indeed we have not in the Engliſh language any regular inſtructions for all the ſucceſſive portions of work to be performed in the conſtruction of a good clock, which want is much to be regretted ; for, until the clock-maker by profeſſion can proceed in his work on ſcientific principles, he muſt be content to be a mere ſlave of imitation in an art, which is capable of affording him genuine pleaſure, from the opportunities it affords, of calling in ſcience to his aid in every ſtep that he takes, through an infinite variety of practical conſtructions. It would tranſcend the limits preſcribed to our plan, ſhould we enter into a detail of all the minutiæ of the art, but as none of our predeceſſors have given the mechanician any information on this intereſting ſubject, we will give a ſuccinct account of the principal operations, as they preſent themſelves in ſucceſſion, which, if it may not afford the expert and informed workman much inſtruction, will, we preſume, gratify the curioſity of the inquiſitive mind, as far as the detail goes.

The firſt requiſite to be determined, is the kind of machine to be made choice of ; *viz.* whether the clock is to be portable or fixed ; how long it ſhall go at one winding up ; whether its maintaining power ſhall be a ſuſpended weight, or a ſpring ; what kind of a dial plate or face it ſhall have for the indication of time ; what ſhall be the nature of its eſcapement ; of what materials its pendulum ſhall be compoſed ; what ſhall be the time of a vibration ; and whether or not it ſhall have the ſtriking work : all theſe and ſimilar determinations, muſt be made before the work is put into hand. We will ſuppoſe that a portable eight-days clock, with a half-ſeconds pendulum, and a ſpring for a maintaining power, is fixed upon as the inſtrument to be made, which we will take as an example, on account of the variety of the parts which ſuch an inſtrument conſiſts of ; and, to render the account more complete, we will ſuppoſe that it be required to go whilſt it is wound up, and that, for the ſake of accuracy, it have the dead-beat eſcapement, and a compenſation pendulum ; the laſt of which is not very uſual in a portable clock.

The going Part of an Eight-days Clock.

1. *Calculation.* Having determined upon the kind of clock to be made, the firſt thing to be done, and that in which the clock-maker is generally deficient, is, to calculate the movement, or proper number of teeth in the wheels, and of leaves in the pinions, of the going part of the mechaniſm. Dr. Derham, in his "Artificial Clock-maker," has treated this ſubject at conſiderable length, and has laid down rules which have tended more to puzzle than aſſiſt the workman in the choice of his numbers ; he propoſes to take at random a certain number of vibrations per hour for a pendulum of an aſſumed length, to repreſent his train, and then to find the factors or numbers, which, uſed as multipliers, ſhall give the requiſite product, or nearly ſo ; after which each factor is repreſented by a ratio of two optional numbers, to conſtitute a wheel and its pinion. We will not follow the Doctor through his proceſſes here, but merely obſerve, that, by calculating his whole movement at one operation from an aſſumed number of vibrations, he has introduced a variety of ſuch trains into portable clocks and watches, as make a vibration of the ſhort pendulum, and an oſcillation of the balance, no exact fraction of a ſecond ; in ſhort he has begun at the wrong end of the buſineſs ; has firſt fixed on the length of his pendulum in inches, without conſidering exactly the number of vibrations it would make, and then calculated a train that would ſo nearly ſuit it, that the adjuſtment for time by the bob, would compenſate the defect of the numbers ; the conſequence has been, that the exact value of a vibration in a portable clock, and of an oſcillation in an ordinary watch, has hitherto been diſregarded in the conſtruction. On the contrary, we recommend to the clock-maker, firſt to fix upon his number of vibrations per ſecond, and then to calculate the true length of his pendulum, and exact value of his train agreeably to the number of vibrations per ſecond that he previouſly determined. The moſt ſimple way of calculating the numbers proper for the movement of any clock, intended to ſhow ſeconds, is, by dividing it into three portions, and then by calculating the wheels and pinions for each ſeparate portion, by a ſeparate calculation, beginning at the bottom of the train ; thus, we firſt fix upon the pinion of the hour arbor to be, ſuppoſe 8, which is a good practical number ; and as our piece is to go eight days, we will make the

the fuſee to revolve in 12 hours, which conſtruction will require the great wheel on its arbor to be 8×12, or 96, becauſe the pinion of 8 revolves, with the minute hand on its projecting pivot, in one hour; hence if we divide 192, the number of hours in eight days, by 12, the time of one revolution of the great wheel, the quotient 16 will be the number of effective ſpiral grooves neceſſary to be cut on the circumference of the fuſee, in order that the piece may go juſt eight days. This portion of the movement is not, however, called a part of the train, but only determines, as has been ſaid, the time that the clock ſhall continue to go after each winding up of the maintaining power; and it is eaſy to conceive, that if a fuſee or a barrel, with 24 turns of the catgut or chain, were placed on the hour arbor, the clock would go a natural day without the large wheel; and alſo, that if an intermediate wheel and pinion were placed on the arbor between the hour arbor and the great wheel, the time of going might be prolonged to 10, 12, or even 20 times eight days, but then the maintaining power muſt be proportionably increaſed, which circumſtance renders ſuch a conſtruction by no means deſirable in a regulator, particularly as the auxiliary ſpring now in uſe will keep the piece in motion during the act of winding up.

The remaining portion of the movement is properly called the *train*, including thoſe wheels and pinions only, which are uſed for counting the vibrations made in an hour; the train is moſt eaſily aſcertained by two calculations, one for the two wheels and two pinions which multiply the minutes into ſeconds, and the other for that wheel and pinion, or thoſe wheels and pinions, which ſubdivide the ſeconds into vibrations; the former of theſe two portions of the train, like the firſt portion of the movement, or portion for the period of continuance, is the ſame for all clocks, let the time of vibration be what it may, a circumſtance not uſually conſidered; the ratio of velocity to be gained by the pinion on the arbor of the ſeconds hand, compared with the wheel on the arbor of the minutes hand, is required to be 60 : 1; which effect might be produced by one wheel of 300 teeth, and a pinion of 5 leaves, as is done in ſome of the ornamental French pieces; but the ſize of the wheel is cumberſome, therefore a pair of wheels, with a pair of pinions, one conſtituting a ratio or vulgar fraction equal in value to 8, and the other equal to $7\frac{1}{2}$, making $8 \times 7\frac{1}{2} = 60$, or any other two numbers making a ſimilar product, will produce the ſame effect with fewer teeth; for if the pinions be each 8, the wheels, in this caſe, will be reſpectively 64 and 60, the compound ratio $\frac{8}{64} \times \frac{8}{60}$ being equal to the ſimple $\frac{1}{60}$; and, by the ſame proceſs, if pinions of 10 had been choſen, the wheels would have been $8 \times 10 = 80$, and $10 \times 7\frac{1}{2} = 75$, which numbers would indeed have leſs friction than the preceding ones, by reaſon of their teeth acting at leſs depth, the diameters of the wheels remaining the ſame, and would moreover be capable of acting more behind than before the line joining the centres of the wheel and pinion; in like manner, pinions of 6 would require wheels of 48 and 45, and pinions of 12 wheels of 96 and 90, as may be ſeen in *Table* II. in our ſubſequent article, denominated CLOCK-*movement*.

The laſt portion of the movement, or ſecond portion of the train, for a half-ſeconds pendulum, will require only one wheel of 60 teeth on the ſeconds arbor, properly ſhaped for the eſcapement; for as one tooth in the dead-beat and common anchor eſcapements eſcapes completely at two vibrations of the pendulum, 60 teeth will eſcape, that is, a whole revolution of the ſeconds hand will be made, in 120 vibrations; if, however, the pendulum had been required to vibrate ſeconds, the wheel in queſtion, called uſually the ſwing wheel, in oppoſition to the crown-wheel, which requires another eſcapement, would have demanded only 30 teeth for that purpoſe; and if three vibrations had been fixed upon, the number to correſpond muſt have been 90, otherwiſe there muſt have been a wheel and pinion of the value of 3, like $\frac{8}{24}$, or $\frac{10}{30}$, in addition to the uſual ſwing-wheel of 30; or, which is the ſame thing, a wheel and pinion of the value of 6, like $\frac{8}{48}$, or $\frac{10}{60}$, muſt have been introduced between the ſeconds arbor and a pallet, or ſwing-wheel of 15. (See *Table* III. under CLOCK-*movement*.) Thus all the variety in the calculation of trains, where ſeconds are indicated, is confined, as we have intimated, to the laſt portion of the movement, and the calculation itſelf is ſo ſimple, that the mere altering of the numbers of the pallet-wheel will convert a clock with a ſeconds pendulum into one with half-ſeconds, and *vice verſâ*.

2. *Notation of the Numbers.* The calculation of numbers ſuitable for an eight-days clock with a half-ſeconds pendulum being thus readily obtained by three ſimple operations, which may be had by mere inſpection from the three tables contained in the article CLOCK-*movement*, the whole may be repreſented, and its value eſtimated again by a compound fraction thus: *viz.* $\frac{8}{96}$ of $\left.\frac{8}{64} \times \frac{8}{60}\right|$ of $\frac{1}{60 \times 2}$ of 12 hours, or, which is the ſame thing in effect, thus, $\frac{8}{96} \times \frac{8}{64} \times \frac{8}{60} \times \frac{1}{60 \times 2} = \frac{512}{44236800} = \frac{1}{64800}$ of 12^h, or 86400 vibrations in 12 hours, which is the time of a revolution of the fuſee, and great wheel, 96, on its arbor, and therefore $\frac{86400}{12}$, or 7200 vibrations, each of half a ſecond in duration, in one hour, conſtitute the value of this train. This mode of notation gives the value better than any other perhaps that has been adopted; but the poſition of the wheels and pinions will be better underſtood from the ordinary mechanical method of writing them down; thus:

Great wheel 96
  Pin. 8—64 hour wheel
    Pin. 8 —60 ſecond wheel
      Pin. 8—60 ſwing wheel
        2 pallets.

Indeed it is difficult to write down the movement by any one notation that ſhall expreſs, at the ſame time, both the value and poſition of the wheel-work, on which account we recommend to the workman to write down his numbers by both forms, taking care in the method, by compound ratios, to put all the drivers under the line of diviſion, and all the driven ones above; ſo that when an aſcending movement is repreſented, the wheels may be the denominators, and when a deſcending one, the pinions. In our mode of calculation, from the bottom of the train, the notation muſt be, as we have made it, aſcending.

3. *Proportioning.* The calculation of proper numbers being made and noted down, the next ſtage of the work is proportioning the diameters of the wheels and of their reſpective pinions, ſo as to tranſmit the maintaining power from the fuſee, or barrel in an ordinary 30 hours clock, to the pallets, and thence to the pendulum, to compenſate the loſs of motion which, when unaided, it would ſuſtain from friction and the reſiſtance of the air. If a wheel and pinion were to be made like two rollers, preſſing their edges againſt one another,

other, to produce a communication of rotatory motion, their diameters might and ought to be in geometrical proportion directly as their calculated numbers of teeth; but the force of the maintaining power would be too great to be ſuſtained by mere friction at the points of contact of ſuch rolling wheels and pinions; they have therefore been neceſſarily indented, and their teeth mutually inſerted ſo far into their correſponding ſpaces, as to prevent the revolution of one wheel or pinion without a correſponding motion produced in the next adjoining, which would not be the caſe with rollers, if a conſiderable force impelled them at one end of the train, and at the ſame time a retarding force oppoſed them at the other; for their ſurfaces, at the point of greateſt oppoſition to free motion, would mutually rub without effecting a communication of rotary motion beyond ſuch point. If now we call the points of contact of the two rollers, made in geometrical proportion to each other, or, in other words, the points where they pitch againſt one another, the pitch-line, and conceive a number of projecting little levers, or teeth, fixed at proper intervals from each other at theſe points of contact, in the circular pitch line of each roller, we ſhall have a true idea of two wheels properly proportioned to act together, which, when of unequal diameters, will not now be in geometrical proportion to each other, by reaſon of an equal lever, or length of tooth, being added to each ſeparately, after they were in exact geometrical proportion; moreover, it will be eaſily apprehended that the deviation from their original proportion, in the ſtate of rollers, will be the greater, the greater their diſparity of numbers. Hence it will be readily conceived, that the due proportioning of wheels and pinions is an important object in clock-making, for, ſuppoſing the teeth reſpectively of the true epicycloidal forms, inveſtigated under CLOCK-*movement*, unleſs the reſpective ſizes be properly adjuſted, the tranſmiſſion of the maintaining power, and communication of motion, will both be unequable, and the mechaniſm ſubject to rapid deſtruction. The uſual mode of proportioning, or ſizing wheels and pinions, as it is often called, is, firſt to make both a little too big for the propoſed calliper, and then, having rounded all the teeth of the pinion and a few of the correſponding wheels, to diminiſh the latter in the lathe, or turning frame, gradually, until, by ſucceſſive trials in the clock-frame, they are found to act at a proper depth, when placed in the pivot-holes previouſly made; this vulgar mode we reprobate, as calculated to deſtroy the due practical proportions, and hope to ſee it baniſhed from the workſhops by the general adoption of a better method, which we have now to propoſe.

In proportioning wheels and pinions, after the numbers of their teeth are determined upon, two particulars are to be attended to, the coarſeneſs or ſolidity and the ſhape of the tooth; the former may be expreſſed by the number of teeth per inch in the circumference of the wheel; and the latter by the denomination epicycloidal: if a tooth were rounded in a circular ſhape, which we by no means recommend, the pitch-line would be conſidered as at one half the breadth of the tooth from the extreme edge; but when it is rounded, as we have recommended in our article CLOCK-*movement*, in an epicycloidal ſhape, or as the workmen call it, the *bay-leaf* form, Hatton has found, from numerous experiments, that the depth, or diſtance of the pitch-line from the circumference, will generally be $\frac{3}{4}$ of the breadth of the tooth in any wheel or pinion; and as the epicycloidal is the beſt ſhape for the regular tranſmiſſion of force and velocity, we will adopt it as the beſt for practice. We have juſt ſaid that when an epicycloidal-tooth is uſed, the diſtance of the pitch line from the end of the tooth is equal to $\frac{3}{4}$ of its breadth, and if we ſuppoſe the tooth and ſpace cut to be reciprocally equal, we ſhall have the true acting diameter of any wheel or pinion greater than the geometrical diameter, which Camus calls alſo the primitive diameter, by $\frac{3}{4}$ of a tooth or ſpace, on each ſide of the centre, or $1\frac{1}{2}$ in the whole diameter; let now a ſpace or a tooth be called a *meaſure*, and there will be double the number of meaſures as teeth in any wheel; alſo let theſe meaſures of the circumference be reduced into meaſures of the diameter by the uſual ratio, of $3.1416 : 1$, and then $1\frac{1}{2}$ added to ſuch geometrical meaſures of the diameter will give the proper acting diameter, which may be expreſſed in inches and parts when the meaſures per inch are known. For inſtance, let our great wheel and its pinion $\frac{8}{96}$ be taken at 12 teeth per inch at the pitch-line, which may in practice be more or leſs, according to the thickneſs of the metal compared with the maintaining power as modified at the wheel's circumference; the number of meaſures of the great wheel is 192, *viz.* 96 teeth and 96 ſpaces, each meaſuring 1-24th of an inch; then as $3.1416 : 1 :: 192 : 61.1$; therefore, if to the geometrical diameter expreſſed by 61.1 meaſures there be added 1.5, the ſum 62.6 or $62\frac{6}{10}$ will be the acting diameter in the ſame denomination, which are ſo many 24th parts of an inch; but $\frac{62.6}{24}$ gives 2.6 inches for the full acting diameter of the wheel in queſtion:—again, the pinion 8 has 16 ſimilar meaſures in its circumference, and by the ſame proportion the diameter will be 5.09 meaſures; to which if 1.5 be added, the acting diameter will be $5.09 + 1.5 = 6.59$, or with ſufficient accuracy $6\frac{6}{10}$, which divided by 24 as before, will give the ſame $\frac{27}{100}$ of an inch, or ſomewhat more than a quarter for the acting diameter of the pinion. Upon theſe principles Hatton ("Introduction to the Mechanical Part of Clock and Watch-work," page 334,) has conſtructed a table of the ſizes of pinions meaſured diametrically, and compared by a pair of callipers with a given number of teeth and ſpaces, in their correſponding wheels, which many workmen copy in practice; but as his calculations are founded on a ſuppoſition that the ends of the teeth are circular, requiring unity as the ſupplemental portion, we find them differ eſſentially from Berthoud's determination in his "Eſſai ſur l'Horlogerie," p. 172, tome i. and ſhall therefore inſert here a new table calculated on a ſuppoſition that the curve is epicycloidal, and that the circumference is to the diameter as $3 : 1$, inſtead of $3.1416 : 1$; the reſult of which mode agrees very nearly with Berthoud's experiments on the proper ſizes of wheels and pinions, and therefore we recommend it to the notice of the accurate workman.

Teeth

Teeth in the Pinions.	Meafures of the Wheel for a Diameter of the Pinion.
10 - - -	8.1
11 - - -	8.8
12 - - -	9.5
13 - - -	10.1
14 - - -	10.8
15 - - -	11.5
16 - - -	12.1

The procefs by which this table is calculated is fimply this; multiply the pinion by 2 for the meafures in the circumference; divide by 3 for the diameter, and add thereto $1\frac{1}{2}$ for the acting fize; thus for the diameter of a pinion of 6, it is $\overline{6 \times 2 \div 3 + 1\frac{1}{2}} = 5\frac{1}{2}$ or 5.5; namely, $6 \times 2 = 12$, and $\frac{12}{3} = 4$ and $4 + 1.5 = 5.5$ for the meafures; which laft quantity taken by the callipers acrofs the extreme edge of the wheel will be 3 teeth and $2\frac{1}{2}$ fpaces, or 3 fpaces and $2\frac{1}{2}$ teeth, which are here fuppofed to be cut but not rounded.

The application of this table, it is prefumed, cannot be eafily miftaken by any workman who underftands that the figures in the fecond column, to the left of the decimal point, mean fo many meafures, either teeth or fpaces, and the figure to the right of the faid point, fo many tenth parts more of a meafure to be added to the integral meafures. It may be proper to add here that a proportioned pinion muft be made fomewhat fmaller for a fmall wheel than for a large one, and alfo fmaller when driven than when it is the driver. We now know the numbers of our movement, and alfo that whatever the diameters of the wheels may be, our pinions of 8 muft be turned in the lathe till their diameters are precifely each 6.8 meafures, or three teeth and very nearly four fpaces, (taken by a pair of pinion callipers from their refpective wheels, in a ftraight line acrofs the ends of the teeth) either before or after they are flit, as the operation of dividing and cutting is called by the workmen. The diameters of the wheels are ufually made to diminifh as the train afcends, probably becaufe the force to overcome their inertia diminifhes, and the friction alfo is lefs in fine teeth with flender pivots, than in coarfe ones with thick pivots: indeed there feems to want a ftandard rule for the guide of workmen in this particular. Having taken the great wheel at 12 teeth per inch, meafured at the pitch line, we will take the centre wheel of 64 at 14, and the fecond wheel of 60 at 16, which will make fomething like a regular diminution in the fizes in the afcent of the train, and allow us room enough in our plates for the reprefentation. From thefe data, by the help of the foregoing directions, we readily afcertain the requifites for drawing the calliper as expreffed in the fubjoined table.

Table of Wheels and Pinions.

Wheels.		Teeth per Inch.	Acting Diameters in Inches.	Geometrical Diameters meafured from the Pitch Lines
Great wheel	96	12	2.60	2.55
Its pinion	8	12	0.273	0.21
Centre wheel	64	14	1.514	1.46
Its pinion	8	14	0.234	0.18
Second wheel	60	16	1.24	1.19
Its pinion	8	16	0.207	0.16
Swing wheel	60	16	1.24	

Pennington, of Camberwell, the ingenious mechanift who conftructed Mr. Mudge's time-piece, and gave the drawings in Mr. Mudge's pamphlet, has paid particular attention to the fubject of fizing wheels and pinions, and has publifhed a fmall pamphlet, recommending the ufe of his method of calculation by a fector of a peculiar conftruction; but we do not find that its ufe has become general. On conferring with him, we were informed that his practice is, to add $2\frac{1}{2}$ meafures of the geometrical diameter to the wheel, and $1\frac{1}{2}$ to the pinion, in watch-work, when the wheel is the driver; and $1\frac{8}{10}$ to each, when the pinion is the driver. This rule, it will be feen, differs very little from our theory above laid down, where we obferved that the driver ought to be fomewhat larger than the proportion affigned by the addition of $1\frac{1}{2}$ parts or meafures to each, and more particularly where the wheels have fmall diameters, as is the cafe in watch-work. But, as the good action of wheels and pinions depends upon their being duly proportioned and callipered, as well as on a proper fhape being given to the teeth, the latter of which requifites is defcribed under Clock-*movement*, we will not fatisfy ourfelves with having given our own method of fizing, which it is poffible the unlettered portion of the workmen may not underftand, by reafon of its requiring fome knowledge of arithmetical proportion, but we will add moreover the method of fizing pinions practifed and recommended by F. Berthoud, in his "Effai fur l'Horlogerie," which is as follows; *viz.*

No. of Teeth. *The full or acting Diameter of the Pinion.*

4 = two full teeth of the wheel, unrounded, and the fpace between.
5 = three teeth, rounded from point to point.
6 = three full teeth, unrounded.
7 = three full teeth and a quarter of a fpace beyond.
8 = four teeth, rounded, from point to point.
9 = fomewhat lefs than four full teeth.
10 = four full teeth.
11 no meafure given.
12 = five full teeth.
13 no meafure given.
14 = fix teeth, rounded from point to point.
15 = fix full teeth.

The pinions in watches, he remarks, muft be fmaller in comparifon with their wheels than in clocks, agreeably to what we have above faid.

Copioufly, however, as we have treated the fubject of proportioning the fizes of wheels and pinions in a train of wheel-work, we think the fubject of fuch importance, that we are unwilling to fatisfy ourfelves with merely having explained, and illuftrated, by an example, the method of converting geometrical into practical dimenfions, but hope to render the bufinefs ftill more familiar by an extenfive table containing the geometrical diameters of all numbers from 4 to 64, and alfo twenty different variations in the ftrength of the tooth which we have newly calculated on purpofe. The data, on which the table is calculated, have been already explained, and its application, it is prefumed, is fo eafy, that the geometrical diameter, in inches and decimal parts, of any wheel or pinion contained therein, may be feen by infpection, and immediately converted into the proper practical diameter, by the fimple addition of the quantity of engagement of the tooth, at the bottom of the fame vertical column, out of which the geometrical diameter is taken, which addenda are calculated on a fuppofition that the teeth are intended to be rounded of an epicycloidal form.

Use of the Table.

1. In the preceding table, the figures at the top of each column, from 4 to 24, denote the numbers of teeth per inch, and those at the left hand, from 4 to 64, denote the numbers of such teeth in the respective wheels and pinions, and the squares, formed by the vertical and horizontal columns intersecting each other, contain, in inches and decimal parts of an inch, the geometrical diameters of the wheels or pinions so circumstanced, to which diameters, if the quantity of engagement entitled, "addenda" at the bottom of the vertical column be added, the sum will be the practical size of the wheel or pinion standing at the left hand of the said horizontal column; for instance, let us take our centre wheel of 64 of 14 per inch, and we shall find at the intersection of 64 at the side and 14 at the top, 1.46 for the diameter, and under it .054, as the quantity to be added, which together make 1.514, agreeably to our former calculation; also, if we take its pinion 8, the intersection of 8 at the side and 14 at the top is 0.18, and the quantity to be added again .054, the sum of which is 0.234, as before. The application of the table to all other numbers, both of teeth in the whole, and teeth per inch, is equally easy and accurate; and even if the numbers run too high for the vertical columns, like our great wheel 96, the result may be as well obtained by taking the halves, or other component parts, separately, and using their sum afterwards as a whole; for half of 96 is 48 and the intersection of 48 with 12 per inch is 1.27, which doubled gives 2.54 for 96, to which add .063 and the practical diameter is 2.603 as before determined; or otherwise take out for $50 + 46$ and the sum will be $1.32 + 1.22 = 2.54$ for the geometrical diameter again as before. This mode of application renders the table unlimited in its extent.

2. But the determination of the practical diameter of a wheel, suitable for a given number of teeth, of a given strength, is not the only use of this table; any two of the three things contained being given in clock and watch-work, the third may be found by inspection, of which the preceding is but one variety; as another exemplification, if it were required to cut a wheel of some given dimensions into a given number of teeth, the size of the cutter, which is of great importance, may be immediately ascertained; for, supposing that a wheel of 1 inch diameter be required to be cut into 45 teeth, if we follow the column 45 horizontally towards the right hand till we come at .95, which has .05 for its epicycloidal addition, the sum 1.00 or 1 is found in the column 15 per inch, which denotes twice the thickness of the cutter; and though the sum may seldom be found, in other instances, to be so exact without a fraction, yet the nearest number to the given diameter is always readily found, and if the difference between the teeth per inch, in the columns next above and next below, be taken, the proportional part, properly applied, will give a decimal quantity to be added to the thicker cutter, or lower number per inch, provided very great accuracy be requisite in the thickness of the cutter.

3. When the cutter and dimensions of the wheel are given without the number of teeth, which may be the case in some instruments with rack adjustment work, where calculations are out of the question, come down the horizontal column from the teeth per inch suitable for the cutter, till the diameter given is met with; thus in the column of 5 per inch, for a wheel of 2 inches, the addition .15 added to 1.85 makes 2.0 exactly, and this coincidence happens in the horizontal column 29, which number will therefore be that of the wheel, for which the engine for cutting must be set to perform the requisite work. Thus the table is not only extremely serviceable to the clock-maker, but to all instrument-makers where wheel-work is required.

4. Lastly, when the number of teeth per inch is not ascertained in a wheel, and the diameter of a corresponding pinion of a given number is wanted, the measured diameter of the wheel, excluding the rounded ends of the teeth, will be at any time sufficient for finding, by the table, the corresponding pinion, and *vice versâ;* for supposing the wheel to be 48, and its diameter, exclusively of the rounded ends of the teeth, 1.7 or $1\frac{7}{10}$ inches; from 48 on the left hand vertical column proceed horizontally till 1.7 is found, which will be in column 9 per inch; then in that vertical column ascend till the given pinion, 8 for instance, stands opposite on the left hand, and its geometrical diameter is .28, to which, if its epicycloidal addendum be added, *viz.* .083, the sum .363 will be the practical diameter of the pinion wanted: and in this way any wheel or pinion, previously made for a foreign purpose, may readily and accurately be made a portion of a clock-movement; and the calliper made accordingly.

4. *Callipering.*—We come next to laying down the plan or calliper of the clock-movement on pasteboard to be transferred to the plates of the frame when properly hammered, filed, and scraped, or planed; the disposition of the calliper depends not on the acting, but on the geometrical proportions of the wheels and pinions, conjointly with the disposition of the circles of indication on the face; when the wheels are small, such as we have chosen for our example of a half-second's pendulum, the distance from the minute to the second hands will not be too great for an ordinary face, if the arbors are pivoted in a straight line, as in *fig. 3*, of *Plate* X. where the dotted circles, taken from the last column of our TABLE of *Wheels* and *Pinions*, represent the geometrical proportions, or the places of the pitch-lines, and the complete circles taken from the column of "acting diameters in inches," are supposed to coincide with the extreme ends of the teeth; hence the little spaces contained between the dotted and complete circles, at each side, represent the additional measure and half of each wheel and pinion, such as were determined by calculation, to convert the geometrical into the actual size, or such as are given by the large TABLE of *geometrical diameters* and *addenda.* It is evident, therefore, to the eye, that the distance between any two arbors or pivot holes is always equal to the sum of the geometrical radii of the wheel and pinion, which act together; this consideration renders the business of callipering very simple; for, the centre wheel of 64 being described from any convenient point in the given plane, a portion of a larger circle, A B, may be described with an extent equal to $\frac{1.46+0.18}{2} = .82$, or $\frac{82}{100}$ of an inch, which is half the sum of the geometrical radii of the wheel 64, and of its pinion 8, and the pivot hole of the pinion may be in any point of this chord line; we have fixed upon a point in a line parallel to the side of the plate, from which as a centre we describe the second wheel of 60, and also the pinion of 8 on its arbor, to be actuated by the centre wheel of 64; we now take another sweep from this determined point or pivot hole, with the extent $\frac{1.19+.16}{2} = .67$, or $\frac{67}{100}$ of an inch, which is again half the sum of the geometrical radii of the second wheel and its pinion, according to our table; and the pivot hole of the seconds arbor, or pallet wheel, may be in any point of the chord C D; but we have said we proposed to have all the pinions in a straight line; another

another point is consequently fixed upon in a line parallel to the edge of the plate, which could not have been the case, if the wheels had been large, like those usually adopted to sustain the great maintaining power of a seconds pendulum. Again with the extent $\frac{2.55+.21}{2} = 1.37$, or $1\frac{37}{100}$ inches, or sum of the geometrical radii of the great wheel and centre pinion, which it actuates, we describe the portion of a circle E F, in any point of which the pivot hole may be placed for the fusee arbor; we have placed it, in our calliper, in a point at right angles to the line of the centres of the train, which is a matter of option, and the spring barrel may be either above, below, or on one side of the fusee, as fancy, or the room left by the other work, may direct. From what has been here said, it will be easy to conceive that there is almost an endless variety in calliper-drawing, the disposition depending on the variable sizes of the wheels and pinions of a movement, compared with the distance from the seconds to the minute-hand arbors; but the particulars we have here detailed, being thoroughly understood, will suffice as a guide in all possible cases; for, supposing a face to be previously given, and the centres for the minute and second hands already made, the pivot hole for the second wheel may easily be determined by intersection from the two given centres with the respective extents as above determined; provided the diameters of the wheels be calculated large enough for the distance of the given centres; that is, provided the aggregate of the geometrical radii of the two interposed wheels and pinions exceed the said distance.

As we intend to give a particular account, at some length, of the various kinds of pallets, under the article ESCAPEMENT, we shall here satisfy ourselves with a brief delineation of the dead-beat pallets, which we have proposed to adopt in our half seconds little clock, and defer, for the present, our account of its peculiar properties. The number of teeth in the pallet-wheel has been determined to be 60, of which any portion less than half may be chosen to be included between the points of the pallets, as will be seen hereafter; we will assume sixteen as a suitable number for a convenient construction; then, as 16 teeth bear the same proportion to 60, the whole number, that 96° do to 360°; from the point *a*, at the extremity of the wheel, in the line of the centres, we set off *a b* and *a c*, each equal to 48°, and from the points *b and c*, draw tangents which will meet at the point *d*, which point will be the required centre of motion for the axis of the pallets: from this point *d*, with the extent *d b*, we draw the curve lines *b e* and *c f*, for the extremities of the pallets, and also parallel thereto, with a smaller ex-extent; two other curves for the interior limits of the pallets, care being taken that the thickness of the pallets, or space between the two concentric curves, be equal to almost one half of a space contained between the extreme ends of two contiguous teeth; the body of the pallets may then be described at option by two curves from the centre of the pallet wheel, reserving a little semicircular portion in addition, for the centre of motion. Had we fixed upon 12 teeth only to be contained between the points of the pallets, the centre of motion would have been, as appears in the figure, nearer the pallet-wheel, as at the interior edge of the body of the pallets; and if more teeth than 16 had been taken, the point *d* would have been more distant than is represented, and the pallets would have required a stem to have brought them down low enough; so that the shape, as well as size of the pallets, depends on the number of teeth included between their acting points, it being advantageous for the action that two lines, drawn from the centres of motion of the pallets and the pallet-wheel respectively, to the acting points, should always form a right angle. With regard to the sloping faces of the pallets, their direction is determined geometrically from the angles that the pendulum is required to pass through in its vibration before the wheel escapes, which is therefore called the angle of escapement: we will not attempt here to ascertain what angle of escapement is best for a given angle of the whole excursion, but assume it, for our present purpose, at 2° on each side of the perpendicular, as a guide for the slope of our intended pallets. From the centre of motion of the pallets, *d*, with any extent, *dg*, therefore, we describe the small chords, *g h*, and *i k*, from the dotted tangent lines prolonged, and set off from *g* towards *h*, also from *i* towards *k*, 2° each, and draw two dotted lines from the point *d*, to the said chords, so as to contain each an angle of 2°; then if a short line be drawn from the upper interior to the lower exterior intersection of the dotted lines with the curved ends of the right hand pallet, it will give the proper slope as seen in the figure; also, if another short line be drawn from the lower interior to the upper exterior intersection of the left hand pallet, it will give its proper slope, and the plan of the pallets will be finished.

The spring box, as we have said, may be placed either above the great wheel of 96, or below it, which is more usual, as at G, in such a situation that the band or chain may wind round both it and the fusee attached to the arbor of the great wheel, without interfering with any part of the movement. We shall have occasion to speak more minutely respecting the requisite size of the spring-box, when we come to treat of the articles MAINTAINING *Power* and MAIN-*spring*.

The calliper of the going part being thus finished on pasteboard, we may proceed to draw the end and side lines to enclose the wheel-work, taking care to leave space enough for the wheel-work of the striking part, and for the ends of the pillars not to interfere with the movement; the space included within the four bounding lines, which may constitute either a parallelogram or a square, limits the size and shape of each of the plates, which, together with the pillars, usually placed near their corners or edges, constitute the frame of the clock-work.

We might here extend our account of the preparation of the plates for receiving the calliper, but as the processes of hammering, filing, and scraping are manipulations familiar to the mechanician, as well as to the labouring workman, we may be allowed to pass over them without any further notice, than that we strongly recommend planing to be substituted for scraping, agreeably to the practice of mathematical instrument-makers, which operation makes an even surface.

The calliper for the striking part of a clock, which is usually and properly called the clock-part, might now be added to the pasteboard; but as we proposed first to pursue the operations attending the construction of the going-part, which has also been called the watch-part, on account of its watching or counting the time as it passes silently along, we will return to the striking-part hereafter, and preserve our account of the *going-part* distinct.

The calliper drawn on pasteboard may now be transferred to one of the plates, either by pricking through the centres upon the brass plate, or by delineating again the same figure according to the directions we have given, unless a deepening tool be made use of for callipering the exact depth at which each wheel and pinion have had their action previously examined; this method is very little known in England, and still less used, though it conduces greatly to perfect

perfect action; whenever this tool is used, which is exhibited in our collection of CLOCK-*tools*, *Plate* XXI. *fig.* 6., of course the ultimate delineation of the calliper on the plate must necessarily be deferred till the wheels and pinions are divided and rounded, and their action duly adjusted in the tool, before the transfer is made by means of the fine points of the parallel arbors, used as dividers, for the description of the requisite circles.

5. *The Pillars and Pivot-holes.* We have said that the pillars, which connect the two plates of the frame, and keep them in their parallel position in a firm manner, are placed at the corners or sides of the plates, as at B, B, B, B, B, *fig.* 1, of *Plates* XI. and XII; the reasons are obvious; the work will thus be more firm than if the pillars were contiguous, and they will be out of the way of the wheel-work and cocks; their number may be three, four, or five, as circumstances may require. Before the holes are drilled for the ends of the pillars, the plates are usually pinned together at each end, and filed to the same dimensions, so that one piercing with the drill and opening with a broach, perforates both plates alike, and ensures the perpendicularity of the pillars when they come to be inserted into their places. It is also usual to pierce with a small drill the pivot holes for the arbors of the different wheels while the plates are pinned together, that the arbors may pass across the frame at right angles to the surfaces of the plates, which is an essential condition in the planting of the wheel-work, and requires the workman to drill in as perpendicular a direction as possible, otherwise the plane of the wheel would not be parallel to the surfaces of the plates, and consequently the communication of motion and transmission of the maintaining power would have an obliquity in their direction, which would produce injurious friction among the teeth.

The strength of the pillars depends chiefly upon the maintaining power and scale upon which the works are constructed; in pieces with a heavy weight they must necessarily be pretty thick, but in spring pieces much metal only gives a heavy appearance, without adding to the utility; the length of the pillars, however, is not so optional; for it depends entirely upon the number of turns of the fusee in spring pieces, and of the barrel in clocks with a suspended weight; in our little eight-days' piece, two inches will be a suitable distance between the interior surfaces of the plates to allow for sixteen turns of the fusee, with the addition of the guard-gut, or stop, at one end of the arbor, and the great wheel and double ratchet, with the auxiliary spring (hereafter described) to produce constant motion, together with space for the rim of the centre wheel at the other. The pillars are generally riveted into the back plate, and pass through the front one to shoulders against which the plate rests, in which situation they are fixed by pins passing through their projecting ends; which mode of fixing the plates admits, indeed, of their being readily dismounted, but is by no means so neat as the method of mounting frames for wheel-work used by the mathematical instrument-makers, which ought to be adopted by clock-makers. The method alluded to is, to screw the pillars into the back plate, even with its exterior surface, and to fix the front plate by screws instead of pins, which screws go into the ends of the pillars, and cover the perforations of the plate by means of intervening collars, as represented in the front of our frame, *Plate* XII. *fig.* 1. The preference of this mode consists in its allowing the plates to preserve their surfaces uninjured and perfectly parallel after being dressed, which the act of riveting would distort; besides, when the clock is at any time cleaned, the plates thus mounted are made handsome again, as they were at first, with little trouble, and the general appearance is thus more workmanlike than in the ordinary way. The shape of the pillars seems to be mere matter of fancy, when they are left strong enough to effect their purpose; but custom has sanctioned the bead, or spheroidical enlargement, at the middle.

Main-spring, Barrel, Arbor, and Ratchet.

The frame being put together and ready to receive the works, a suitable spring must be obtained for a small clock from the spring-maker, whose art is distinct, and will form a separate account in its place; the breadth of the spring we will suppose to be an inch, which will require a box or barrel, C, *Plate* XI. sufficiently deep to hold it, and to be of a diameter sufficient to admit of as many effective coils or spirals as will turn the fusee sixteen times round, before its force is expended in unbending itself. Sometimes it may be necessary to try two or three springs before a good one is met with, that will act with a due degree of regularity; and it has been asserted that a spring will act more regularly and be less liable to have undue friction among the coils, if the breadth be gradually diminished from the exterior to the interior end; but we pledge not ourselves for the existence of the fact, though we conceive that the friction of the sides of the spring against the ends of the barrel, will thereby be greatly diminished. The spring arbor must be strong in proportion to the force of the spring, particularly at the pivots, the front one of which must be thick enough to admit of being squared to hold a ratchet, or small serrated wheel, C, at the outside of the frame, (see *Plate* XII.) the teeth of which ratchet must be strong enough to hold the arbor in any situation to which it is turned, which it does by means of a click attached by a screw to the exterior surface of the front plate of the frame; the spring-arbor has a strong pin inserted into it at the middle, within the barrel, on which pin a hole made near the interior end of the spring hooks, while the exterior end is riveted to the circular side of the box; hence it is not difficult to conceive that when the spring fills the box in its relaxed state, and has its coils most close at the rim of the barrel, it may be coiled up close to the arbor in the centre, or, in other words, it may be wound up, by two different methods; either the barrel may be held fast, and the arbor be turned backward by its ratchet, or by a key fitting its square; or otherwise, which is the general and better practice, the ratchet may be suffered to detain the arbor in its place, and with it the interior end of the spring, and the barrel itself, to which the exterior end is riveted, may be turned forwards by a chain or cat-gut attached to it by a knot at one end and wound round it, as seen at C, in *Plate* XI. We have said the latter method is the better, and the reason is, that, when the greatest and smallest forces of the spring are adjusted to the shape of the fusee, or rather the fusee to them, the ratchet cannot be altered without deranging this adjustment. The arbor is turned in a turning-frame with pivots and shoulders sufficiently remote from each other to reach the interior faces of the plates, but to have just so much play endways as will prevent friction; and the chain or gut must be long enough to fill the spiral grooves of the fusee, and have at least one half-turn on the barrel to spare; also care must be taken that the depth or side of the barrel must be nearly equal to the effective length of the fusee, otherwise the gut will be liable to slip off at the ends of it. The remote end-piece of the barrel is soldered fast, and has a large pivot-hole, against which an inner shoulder of the arbor rests, and the nearer end-piece is turned in the frame so large as to be capable of being forced or sprung into a receptacle turned for it, round the inner part of the edge of the circular

cular rim of the barrel, in which situation it rests against a corresponding inner shoulder of the arbor, and completes the barrel; when this adjustable end is to be taken off for the purpose of examining or taking out the spring, a slight stroke at the remote pivot of the arbor will force it out of its place; some skill is necessary for putting the spring into the barrel, when a tool on purpose is not at hand, which will be described among the WATCH-*tools*, and which seems necessary to be more generally used in clock-work to prevent accidents consequent upon a manual insertion of the spring.

6. *Fusee, Ratchet, and Guard-gut or Stop.*—The spring-barrel and its appendages being finished, a rough estimate of the power of the spring may now be made by first coiling the gut, in a proper direction round it a few times till it is nearly all wound up, the arbor being held by its ratchet, or in a vice, and then by suspending a weight to the spare end, such as will just pull the barrel two or three times round from its relaxed state; this weight will denote the smallest power, which suppose to be one pound; then add such a heavier weight as will uncoil so much more of the gut as may be supposed to fill the fusee, and note it, which we will again suppose to be two pounds and a half for the greatest power of the spring; now this proportion of $1 : 2\frac{1}{2}$ or $2 : 5$, may be taken as a guide for the respective diameters of the conical piece of metal, E, *fig.* 1, *Plate* XI, called the fusee, which is introduced to equalize the varying power of the spring, by acting, as it were, with a succession of levers of different lengths, reciprocally proportionate to the power of the spring in any given situation, so that when the power is great it is pulling by a short lever, and *vice versâ*. The piece of solid metal intended for the fusee must be drilled through the centre, and opened with a broach, and then have a steel arbor of considerable strength driven tight into it, by which it is turned into a conical or rather paraboloidal shape, that has its thicker end somewhat smaller generally than the diameter of the barrel, and the other end smaller in the proportion, according to our supposition of $2 : 5$, but sometimes in a greater ratio, without the thickness of the gut; the length of the fusee must be shorter than the pillars by as much as will admit the great wheel and two ratchets, with the centre-wheel behind them, to be introduced between it and the plate at one end, and a contrivance for stopping the revolutions when the spirals are filled with the gut, called therefore the guard-gut, at the other end of the arbor, as we have already said. The fusee may now be grooved into sixteen complete spirals by a fusee-engine, the method of doing which will be explained under this term hereafter; after this operation, a pair of strong pivots may be turned on the fusee arbor, the pivot-holes opened by a pivot-broach held perpendicularly with respect to the faces of the plates, and the fusee introduced into the frame, parallel to the spring-barrel arbor; a hole is now drilled at the large end of the spiral, perpendicularly into the metal, the fusee being taken from the frame, and another hole to meet it from the plane of the thick end, about a quarter of an inch from the circumference, which two holes are just large enough to receive the gut; the latter is then enlarged by a chamfering tool to form a bed for a knot to be made at the end of the gut, when inserted into the hole made in the spiral groove. If now a square be made, either on the front or back pivot, which must project through the plate, accordingly as it is intended to be wound up in the face or behind, and if a key be inserted upon it, the spring may be wound up, and it will appear whether or not the gut is too long, and how much, nearly, which may accordingly be altered. Hitherto the work has proceeded, on a supposition that the fusee has been turned of a paraboloidal shape, and that the spring is perfect at the two extremes, as well as at all the intermediate degrees of tension; but it yet remains to be proved, by mechanical adjustment, that these coincidences have been effected, or are even capable of being accurately effected, without material subsequent alterations in the length of the spring and shape of the fusee; for this purpose a long graduated lever, with an adjustable weight, hereafter mentioned under CLOCK-*tools* by the title of an *adjusting-tool*, (*fig.* 10, *Plate* XXI.) is inserted on the square end of the fusee, at N, when the frame is mounted, as in *Plate* XII. and the weight is gradually removed along the bar, until by trial it is found to be an exact counterpoise to the spring previously wound up a few turns by means of the ratchet on the barrel-arbor; such balance being effected, the spring may be wound up by the adjusting tool, used as a key, till the sixteenth spiral at the top, or small end of the fusee, be filled with gut, in which situation, if the weight of the tool still constitute an exact counterpoise to the power of the spring, it is to be presumed that the spring is properly fixed, with respect to its quantum of intensity, by its ratchet; but if, in the latter situation of the tool, it turns out to be more than a counterpoise, either the spring is of too low an intensity in the present situation of its ratchet, or the fusee is too small at the small end, or both may be so circumstanced; on the contrary, if the tool is not a counterpoise for the spring when wound up, either the spring is set too high by the ratchet, or the small end of the fusee is too thick; a few successive trials of similar adjustment for the opposite ends of the fusee, by an increase or decrease of intensity being gradually given to the spring by means of turning its ratchet, will generally determine whether the failure in the adjustment is occasioned by the spring or fusee, and the former may be shortened, or the latter altered, by a detached tool to run in the groove as it revolves in the turning frame, if a fusee-engine is not at hand; though, it must be confessed that some experience in this business will greatly facilitate the determination of the proper means of final adjustment. We will now suppose the spring fixed, and the fusee adjusted by the tool, so as to render the maintaining power precisely the same at the bottom and top of the spiral groove; the adjustments must next be made for all the intermediate turns of the helix successively, by means of the same adjusting tool with the weight unaltered, the spring arbor also resuming at every trial its original position, which we will suppose to have been marked on the holding tooth of the ratchet. When the spring is good, and the fusee approaching to a conical shape, it will be found on trial, that the maintaining power is too great for the tool of adjustment to balance before it is wound up half way; in consequence of which increase in the maintaining power, the fusee must necessarily be again put into the fusee engine and have its groove deepened so as to make a parabolic curve instead of a straight line from the top to the bottom of the fusee; after this alteration the frame must be remounted, the spring coiled up again to its determined position, and the weight of the adjusting tool kept unaltered in its situation; the intermediate grooves in the helix may not yet be found all sufficiently deep to render the maintaining power equal in its effects throughout the whole length of the fusee, but the adjusting tool will detect the particular places where the power predominates; which places when marked may be again altered in the fusee engine, and the parts replaced in the frame, when, after three, four, or perhaps more alterations of the fusee, and adjustments of the spring, at length the effect produced by the power of the spring is the same

whatever part of the fusee be actuated by the gut; the accuracy of this adjustment is of the utmost importance, and should be minutely attended to, otherwise the piece may be made to vary its rate of going on each successive day of the week, by reason of the irregularity of the maintaining power, unless indeed such a consequence be obviated by the nature of the escapement, or other contrivance, which ought not to be depended upon while there is a fundamental remedy. Hence it is evident that, whenever the original main-spring of a clock (or watch) happens to be broken, or by any means altered, another spring, though of the same dimensions ought not to be substituted, as is often injudiciously done, without a corresponding alteration in the fusee, if found necessary, by a trial of the adjusting tool. Were an optician to put a thermometer tube containing mercury, already hermetically sealed, into an old scale previously graduated, the indication of temperature with such an instrument could not be depended upon to any thing like accuracy. Of the same nature is the probability of an imperfect measure and indication of time arising out of an exchange of the main-spring without a corresponding adjustment in the shape of the fusee, more particularly if the crown wheel escapement happen to be adopted, which is almost constantly under the influence of the maintaining power.

During this labour of adjusting the fusee to the spring, it will occur that the gut might be wound up beyond the end of the fusee, if it were turned more that sixteen times round, on which account a snail piece of soft steel, equal in diameter to the small end of the fusee, independently of the claw or projecting piece, is usually screwed against this end of the fusee at N, *Plate* XI., to prevent the gut from slipping off when it comes to the projection of the claw in question, which contrivance it has been said is called the guard-gut; but it may be remarked, that the gut might wind back again by a second course, like the cord of a kitchen jack on its barrel, when it comes to the snail-piece of the guard-gut; to prevent such effect, there are supperadded a spring, M, screwed at one end to the inner face of the front plate, which plate is taken off in the drawing, and a lever, L, moveable on a pin as a centre, which pin passes through a stud in the front plate, according to the position given in *Plate* XI.; the remote end of the spring, M, stretches itself towards the back plate of the frame, and carries the lever before it; of which the consequence is, that as the gut approaches the guard in winding, it at length meets with the lever, L, and pressing against it drives it forwards till at length a shoulder near its remote end, seen near the pillar, is presented to the claw, N, of the snail-piece, for which it becomes a stop at the instant that the sixteenth spiral is filled by the gut, and the winding is then necessarily finished.

The contrivance for allowing the fusee to turn in the act of winding up, while the great wheel retains its position unaltered, but which prevents the return of the fusee to take place by the pulling of the spring without the great wheel being actuated, is called the *fusee* ratchet; it usually consists of a serrated wheel with sloping teeth, and a click to catch the teeth, like the mechanism already mentioned as being at the projecting arbor of the spring barrel, but with the addition of a spring to press upon the click to keep it in the teeth; the ratchet wheel may be attached either to the end of the fusee, and the spring and click to the plane of the great wheel, or otherwise the spring and click may be at the end of the fusee, and the ratchet wheel on the plane of the great wheel, but the direction of the slope of the teeth will not be the same in both cases, for in one case the wheel drives the click during the time of going, and in the other the click must drive the wheel; it is usual to turn a circular groove between the edge of the ratchet wheel and the circumference of the fusee large enough to form a bed for the click and its spring, which therefore are hid from sight, when the spring is carried by the great wheel; but when it is carried by the end of the fusee, the said groove must be in the plane of the great wheel to answer the same purpose of concealment; the number of teeth in the ratchet wheel is optional, provided they be strong enough to sustain the maintaining power, and numerous enough to prevent a considerable return of the fusee backward after winding, before the click catches a tooth; the construction will be sufficiently understood without further description, from a reference to *fig.* 5, of *Plate* VIII., to *fig.* 7, of *Plate* XV., and to *fig.* 4, of *Plate* XXII. of *Horology*.

7. *Auxiliary-spring.* But we proposed that our piece should continue to go while it is wound up, which effect requires an additional apparatus to the ratchet we have just described, as being usual in an ordinary spring-clock; the addition usually consists of another ratchet-wheel with teeth inclined in a contrary direction, and of a larger diameter, of a circular or sometimes a horse-shoe spring, and of a lever operating as a detent with one end fastened to the inner face of the back plate, and the other resting upon and sliding over the sloping face of the teeth of the large ratchet when the clock is in motion, but which prevents the ratchet's return when the clock is wound up. One end of the spring is pinned or screwed to the rim of the great wheel, and the other end to the plane of the large ratchet, and in this case the small ratchet before described actuates this large one, instead of the great wheel, exactly as above described; and then the large ratchet contracts the spring connecting it with the great wheel, till its resistance in a contrary direction is equal to the maintaining power, in which situation the great wheel is then impelled in the same manner as if it were immediately connected with the small ratchet; the effect of this beautiful contrivance is, that when the clock is under winding, the spring attached to the great wheel being no longer contracted by the maintaining power, immediately endeavours to extend itself, but the large ratchet-wheel, to which it is riveted, is stopped from going back by the end of the lever or detent, which is always in a position to catch the end of some one of the sloping teeth of this ratchet, the consequence of which is, that as the ratchet will not go back, the great wheel is impelled to go forward at the opposite end of the spring by a force, at the commencement of its action, equal to the maintaining power; and this force will continue for a much longer time than is necessary for the winding-up of any clock. This apparatus may be more clearly apprehended by a careful inspection of *fig.* 4, of *Plate* XXII., and of *figs.* 7 and 8, of Brockbank's chronometer in *Plate* XV., which differ in no other respect, but in their size, from the same parts as used in a clock.

8. *Arbors, Pinions, and Wheels.* Hitherto we have said nothing of the manipulation of the arbors, pinions, and wheels of a clock, but have merely spoken of their diameters, numbers of teeth, and respective situations of their pivot-holes. It will not be necessary to enter into a detail of the manner of forging the arbors, or of casting the brass by models of given dimensions, the ironmongers and tool-sellers having on sale sets of wheels, and arbors with pinions of different numbers ready slit, and also pinion steel-wire drawn into a proper shape for the teeth of small pinions, of all which clock-makers usually avail themselves instead of preparing them; otherwise the brass-founders in Chancery-lane, and in other parts of London, as well as in Lanca-

 shire,

ſhire, will caſt wheels to any model at a certain price per pound, which is a great convenience to the workman who has occaſion for unuſual ſizes in his wheel-work.

It will not, however, be deemed foreign to our purpoſe to mention, that it is often found requiſite to ſoften the pinions of ſteel, and their arbors, before the graver for turning can cut them with ſufficient eaſe in the turning frame; this ſoftening is uſually effected by putting the ſteel pieces into a wooden fire for ſome hours, and leaving them to cool gradually as the fire goes out. The wheels are generally croſſed in their original caſt ſtate to make them light, in order to avoid the effect of their inertia, and to prevent friction on the pivots of the arbors; but it is neceſſary to hammer the rims and other parts of a wheel well before they are filed flat, to be put on the arbor for turning, otherwiſe the metal would be too ſoft to wear well, and the teeth of a wheel would not ſtand the graver in the operation of being turned, after it is cut by the engine, in caſe the diameter ſhould require to be reduced, as is commonly done, to work well in its calliper with its pinion. When the wheels are hammered, and filed flat to nearly their exact thickneſs, according to the force they are deſtined to tranſmit, they are turned in the turning-frame to their practical diameters, after being previouſly perforated in the centre, and ſcrewed faſt on a ſuitable arbor, ſuch as is repreſented by *fig* 2, of *Plate* XIX.; they are then in a ſtate to be cut by an engine made on purpoſe, which is not always in the poſſeſſion of the clock-maker, particularly in large towns, but which is uſually kept by ſome individual, whoſe buſineſs is chiefly to cut wheels for the clock-makers at a certain price per ſet. An ingenious workman, of the name of Brown, who lived in King-ſtreet, Seven-dials, but who is now dead, was noted in London for his dexterity and accuracy in cutting clock-wheels, and occaſionally pinions, into any number of teeth; his engine, however, is now in the hands of Mr. Fidler, mathematical inſtrument-maker, Oxford-market, London, who has lately begun to uſe it; but the beſt engine for this purpoſe at preſent in conſtant uſe, belongs to Mr. Edward Troughton, of Fleet-ſtreet, and is uſed by James Fayer, at No. 35, White-lion-ſtreet, Pentonville, London.

This engine, which was contrived and made by the late ingenious mechaniſt Rehe, will round the teeth at the ſame time that it cuts them, if required, and is valued at 300*l.* in its preſent ſtate. As we ſhall have occaſion to treat further of the conſtruction and operations of the CUTTING-*engine*, we ſhall here conſider that our wheels have now undergone their operation, and are returned into the hands of the clock-maker for finiſhing; we cannot, however, forbear remarking here, that the clock-makers of the preſent day have greatly the advantage of thoſe who laboured in the art in the infancy of clock-making, in that they have ſome of the moſt difficult operations in theory, ſuch as dividing and cutting the wheels, and forming the ſpiral groove of the fuſee, done by engines not only in leſs than one-hundredth part of the time, but with infinitely more accuracy, than they could be performed by hand with manual tools; and it is much to be deſired that they would, like watch-makers, have their wheels cut and rounded in the engine at the ſame time; that they would make uſe of the deepening tool, *fig.* 6, *Plate* XXI. for pitching their depth of action; and that they would in that ſtate transfer the diſtances of the pivots to the calliper, as we before recommended; for then the equable tranſmiſſion of motion and maintaining power would be enſured, provided the teeth be of a due ſize and form; the expence in cutting would, indeed, be ſomewhat more, but the labour of rounding by a file would be ſuperſeded, and conſequently the work would be more expeditiouſly, as well as more accurately, performed.

But it has been remarked, by a philoſopher well qualified to make the remark (Mr. W. Nicholſon), that the introduction of new inſtruments, and of new operations, requires the ſame ſpace of time that is neceſſary for inſtructing another generation; ſo much does that facility, which ariſes out of habit, militate againſt the adoption of new practices: we muſt, therefore, ſuppoſe our wheels returned from the engine with their teeth not rounded, and proceed with our detail. When a wheel has been cut, in the ordinary way, by the engine, there are uſually ſome filaments of metal, denominated burs, left at the edges of the teeth by the cutter, as well as general roughneſs on the ſides and at the bottom of the ſpaces; theſe are firſt cleared away by a fine file, juſt thin enough to go into the ſpace left by the cutter, which is called an equalling file, (ſuch as is repreſented in *Plate* XXI, *fig.* 14.) from its ſuppoſed property of leaving all the ſpaces equal, when the burs are removed. The croſſes of the wheel and interior edges of the rim are next dreſſed, firſt by a rough file, then by a ſmooth one, and laſtly by a burniſher of poliſhed ſteel, all ſhaped like *fig.* 17, of *Plate* XXI.; the arbor is next turned in a frame, by a well-tempered tool, or ſtrong graver, like that ſeen in *fig.* 9, of *Plate* XXI., to its propoſed thickneſs, and the pinion reduced to its practical diameter; after which its teeth are rounded, hardened, and poliſhed, each of which operations we will ſuppoſe to be underſtood, and the wheel is riveted on a ſhoulder left on the proper end of the pinion, exterior or interior, as the work may require, if it is on the hour arbor; otherwiſe it may be riveted, or ſtill better fixed by two oppoſite ſcrews, on a braſs collet, which is previouſly ſoldered upon ſuch part of the arbor, to which it belongs, as the place of the pinion which it actuates may require. The French call that portion of an arbor, which is between the wheel and the remote pivot, a *tige*; and that portion a *tigeron*, which lies between the wheel and the nearer pivot. Some of the moſt ſkilful workmen contend that the wheel ought always to be placed on its arbor, ſo as to be equally diſtant from both pivots, and we have ſeen clocks conſtructed with cocks, at the back of the plates, to hold the pivots of projecting arbors, in order to effect this purpoſe, but we will not undertake to affirm that this additional work is compenſated by any advantage thus gained; we rather conceive that the grievance complained of in the ordinary method of pivoting in the plates, *viz.* the alleged unequal preſſure and conſequent unequal friction in the oppoſite pivot-holes, when a pinion is at one end of the arbor, is to be attributed to another cauſe principally; *i. e.* the too great aperture of the pivot-holes: the workmen have a maxim, that "the pivots muſt have play to avoid friction," but they ſeem not always to underſtand what this play means; it certainly ought not to mean, that the holes ſhould be much larger than the pivots which are to turn in them, for in that caſe the pivots would be driven round the interior circumference of the holes, and cauſe the wheel to act at different depths in the pinion, which would be a great evil; the meaning of the maxim is, that the ſhoulders of the arbors ſhould not preſs againſt the plates when mounted, but that each arbor ſhould have a little play in the direction of its length, or, in other words, be left ſo as to be at liberty to move a little backwards and forwards; which condition ſeems requiſite.

We will now ſuppoſe all the wheels and pinions rounded neatly in the bay-leaf form, and their action tried in the deepening tool, with the correſponding pivot-holes drilled with

with drills refpectively proportioned to the propofed thicknefs of the pivots; the next ftep will be to attach them to their arbors: the great wheel, however, notwithftanding what we have faid about riveting, fcrewing, and foldering, is not fixed by any of thefe operations, but is attached to its arbor by a method which admits of its being taken off at pleafure, thus;—a hole is opened by a broach in the centre of this wheel, large enough to take the arbor of the fufee without play, and, when it is preffed clofe againft the end of the fufee, or, in our prefent inftance, againft the plane of the fecond large ratchet, two marks are made, with a fine file, at oppofite fides of the arbor, clofe to the plane of the wheel; it is then taken off the arbor, and two fquare-fided notches are filed carefully in the faid marks of the arbor, but not deep enough to injure its ftrength; a collet with a circular hole, like that at the centre of the wheel, made at one fide of its centre, and with a ftraight-edged flit acrofs the centre from the faid hole, is then put on the arbor, after the wheel has been firft put on, and is pufhed forcibly along the notches of the arbor till, by means of the oblong aperture, it is concentric with the wheel, againft the plane of which it preffes, when in the notches, and keeps it clofe in its place, and at the fame time allows it to turn on its centre without the arbor. The auxiliary fpring is fcrewed or pinned, in the next place, at one end to the great ratchet, and at the other to the great wheel, as before noticed. When the wheel is thus firmly attached to the fufee arbor, with a power to recede but not to proceed, on account of the click, without carrying the arbor with it, it muft be put into the turning frame and examined, as to its being truly centered, and alfo as to its being in a plane perpendicular to the arbor; which trial may detect fome flight alterations, neceffary to be made, to fulfil thefe two conditions: after which, its pivots may be turned to their exact fize, hardened, and polifhed.

The practice of fome workmen is, to folder their collets on the arbors with hard folder, but we difapprove this practice, and recommend foft folder, particularly if the arbors have been before hardened; it is fcarcely neceffary to add, that if the ends of the collets are opened a little within, the folder will there have beds to contain a quantity fufficient to keep the wheel firm on its arbor. What we have here faid will not be equally applicable to the hour or centre wheel, becaufe it is ufually riveted on the end of its pinion, which will require a riveting punch and clamp, on purpofe (*fig.* 16, of *Plate* XIX.) to prevent any injury being done to the pinion. Before the wheels are all firmly attached to their arbors, they muft be tried in the turning frame, or callipers with a ftraight edge for that purpofe, to fee if they are concentric, and that their planes are perpendicular to their arbors, which conditions the workmen call being "in the round," and being "in the flat;" and when properly adjufted, in thefe refpects, they may be finally fixed as above defcribed, and their arbor-pivots finifhed. Should a wheel, that has had its teeth rounded in the engine, be at any time found a little eccentric in the trial, before it is fixed on its collet, which will not happen if the central hole be enlarged with a good broach and with due care, the remedy in this cafe would be, to mark the fide of the wheel which has the longeft radius, and enlarge the central hole carefully on that fide moft, and then to make a new collet for it, after the hole is again made perfectly round, and found to be concentric on an arbor that fits it; but when the teeth have been rounded by hand, the wheel may have the eccentricity rectified on its own arbor, and be again rounded where the teeth have been touched by the graver, which is the common practice, and which conftitutes the greateft recommendation of manual rounding of the teeth.

The files ufed in rounding the ends of the teeth of a wheel are fmooth, and curved on one fide (fee *fig.* 16, of *Plate* XXI.), and have each a projecting pivot at the remote end, which a dexterous workman holds againft one finger of the left hand as a reft behind the wheel, while the right hand guides the file from one fide of the tooth to the other, alternately, with a degree of rapidity which furprifes the fpectator.

We have hitherto fuppofed our piece not to be jewelled, nor bufhed with bell-metal, which addition enhances the price, but greatly diminifhes the friction in the pivot holes: if the holes are carefully enlarged with a good broach, fmall pieces of metal holding ruby, agate, or bell-metal, may be made to fit them exactly, the holes in which may be refpectively equal to the original pivot holes, and then the good action of the wheel-work will not be altered thereby. The friction in the pivot holes is greatly diminifhed too by the application of fine nut-oil; they are, therefore, generally chamfered, or counter-funk, at the exterior furfaces of the plates, in order that the oil may be retained; but what fhould be the exact depth of the bearing part of the pivot-hole, is a matter not abfolutely decided. Mr. Reid, we have feen, prefers, to a counter-funk hole, a conical point, which holds the oil in a globule by cohefion, and which is held by a fmall cock.

In fome clocks which we have feen well-finifhed, the ends of the pivots are conical, and bear againft holes of nearly the fame fhape, not entirely perforated; but we conceive that, unlefs the pillars and arbors were all of the fame metal, the difference of their expanfibilities muft materially alter the quantity of play, lengthwife, at different feafons of the year, and in cold weather create confiderable friction, by affecting the brafs pillars more than the fteel arbors; an effect which the workman probably does not take into his account, who thinks of avoiding friction by fuch a conftruction.

As the pallet-wheel makes many more revolutions than any other in the movement, it is neceffary that the metal, of which it is made, fhould not be very deftructible, particularly when pallets are ufed which rub againft its teeth; we therefore recommend a tempered fteel wheel to be ufed, which ought to be alfo divided and cut with extraordinary care, becaufe any irregularity in the fhape of the tooth, or diftance between the teeth, would injure the efcapement, and produce befides fuch irregularity in the motion of the feconds hand, placed on this wheel's arbor, as would offend the eye. We referve our obfervations on the fhape of the teeth proper for different efcapements to act with, until we treat this part of our fubject more particularly in its proper place.

9. *Pallets.* There is no part of a clock which requires greater nicety in the execution than the efcapement, or part which limits the intenfity and duration of the impulfe given to the pendulum by the maintaining power, and which keeps up the due quantity of motion, that would otherwife be gradually diminifhed to a ftate of quiefcence, by reafon, as we have faid, of the unavoidable friction at the point of fufpenfion, and of the refiftance which the air affords to the folid parts of the moving pendulum: but for the fame reafon that we have poftponed our particular directions concerning the conftruction of the pallet or fwing-wheel, till we come to the article Escapement, muft we alfo fatisfy ourfelves here with a few general directions and obfervations, which apply exclufively to our dead-beat pallets. We have already detailed, under our fubdivifion, entitled *callipering*, the method of laying down the plan of the pallets in queftion; the fhape and dimenfions there afcertained muft be exactly copied, or otherwife projected again, either on one of the plates

plates or on a ſmooth ſheet of braſs, as a plate of trial for the eſcape, which will admit of pivot-holes being drilled, exactly as in the plates of the frame, for the centres of the pallet and pallet-wheel arbors; a piece of good ſteel muſt then be forged nearly into the ſhape of the anchor, compared with the plan on the frame or braſs plate, but ſomewhat larger: after the arbor hole is drilled in the anchor, and enlarged to the propoſed aperture, the requiſite circles may be deſcribed, with extents borrowed from the braſs calliper, by means of a pair of ſmall bullet compaſſes, and the ſlopes may be copied or re-traced for the faces of the pallets; the excluded metal may then be filed away very nearly, and all the ſurfaces be ſmoothed, firſt with fine files, and then with oil-ſtone duſt and oil. It has been ſaid that the breadth of each pallet muſt be ſomewhat leſs than half of a ſpace meaſured from tooth end to tooth end of the pallet wheel, but the quantity of diminution muſt not depend on conjecture; therefore the breadth is left at firſt equal to one half as nearly as can be aſcertained, ſo that the diminution of breadth may be effected by tentative adjuſtment, firſt partially when the wheel has its teeth finiſhed, and when both it and the anchor of the pallets are inſerted on pins urged into the pivot-holes of the frame, or trial plate; and again more minutely when they are fixed on arbors, and mounted in the frame. To enſure the perfect portion of a circle at the extremities of the anchor, we recommend that it be put on a motion arbor, that juſt fits the central hole, and that it be turned in a frame or lathe, like a wheel, before it is cut; for then it is certain there will be no recoil in the pallet-wheel, and ſeconds hand, when thoſe parts preſs againſt the ends of the teeth, during an excurſion of the pendulum; and if the inner circles could be turned alſo after the eſcape is nearly adjuſted, it would be deſireable; however, the point of a graver may trace in the turning frame this inner circle, and then a proper curvi-linear file, made and kept on purpoſe, may take off the interior ſuperfluity of metal. In adjuſting the ſlopes and breadth of the pallets, it will be ſerviceable to inſert an index on the pallet's arbor, after it is finiſhed and the pivots turned, and to mark on the frame plate the quantity of the eſcapement angle, in this inſtance 2° at each ſide of the perpendicular demitted from the pivot-hole, which will be a good guide for the true final adjuſtment of the eſcape. Particular care muſt now be taken that there be as little drop as poſſible, *i. e.* that as ſoon as one tooth has completely eſcaped the face of its pallet, the next acting tooth ſhall be cloſe to the back of the following pallet, ſo as not to ſtrike it with a jerk; the place where the firſt contact takes place between the end of the tooth and interior or exterior circle of the pallet, accordingly as it is the leading or following pallet, muſt be very near the commencement of the ſlope, but not upon it, nor yet on the angular point of interſection. Indeed it is extremely difficult to give complete verbal directions for this delicate adjuſtment, which requires long and attentive practice to do perfectly; for frequently, after the pallets are hardened, which they muſt be as much as poſſible, the ſhape of the anchor is found to be altered, and the adjuſtment of the pallets conſequently deranged: to remedy this conſequence, it is uſual to harden only the pallet parts of the anchor, ſo that by certain ſtrokes given near its arbor, the pallets may be brought in or ſet out a little to rectify them; but after ſuch rectification it will always be neceſſary to try, in the turning frame, or at leaſt by a pair of bullet compaſſes, if the circular parts are again perfectly concentric, without which condition the pallets will not be truly what are called dead-beat.

Hitherto we have conſidered the back pivot hole of the pallets arbor, as being in the plate of the frame, but it becomes neceſſary to cut away that portion of the back plate where the pivot hole falls, by reaſon of the crutch, or little rod of ſteel which muſt be ſcrewed to a collet attached behind the frame to the arbor, to form an L; which contrivance impreſſes the force that the pallets receive from the maintaining power upon the pendulum; the bent end of the crutch is uſually inſerted into a ſlit made in the verge or rod of the pendulum, but when the bent part is divided and encloſes the pendulum rod, it is denominated the fork: the crutch is moſt uſually about one ſixth part of the whole length of the pendulum rod, but there ſeems to be no fixed rule laid down by which its beſt length might and ought to be determined in different caſes, which therefore we think deſerves further conſideration.

But to return to the pivot-hole of the pallet's arbor; this, for the reaſon we have juſt given, is finally placed in a cock at the back of the poſterior plate, which is generally ſo ſhaped as to furniſh alſo a point of ſuſpenſion for the pendulum. (See *a*, in *fig.* 3, of *Plate* XI.) The exact placing of the cock, ſo that the arbor pivoted into it ſhall be perfectly at right angles to the ſurface of the plates, is of the greateſt importance, and therefore it ought to be placed and its ſteady pins fixed, before the original pivot-hole, through which it muſt protrude, is cut away in the plate; for in that caſe the protruding end of the arbor, while in its proper poſition after the adjuſtment of the eſcapement, will be like a fixed arbor on which to ſlide the cock, and fix its poſition before the ſteady pins are applied and the ſcrews fitted to their places.

It is, however, the practice of ſome workmen to adjuſt the eſcapement, by moving the cock before the ſteady pins are inſerted.

We might have noticed, that after the anchor of the pallets is ſcrewed to the collet of its arbor, it ſhould be ſuſpended by the pivots of the verge, which is the name given to this arbor, to try if the weight of each pallet exactly balance that of the other, which may be effected by dimiſhing the thickneſs of the heavier pallet a little by a fine file before it is finally poliſhed; alſo before the crutch is ſcrewed it ſhould be hung on the verge of the pallets arbor, after the pallets are balanced and ſuffered to find their place of quieſcence, in order to find its own perpendicular direction, and then it ſhould be fixed in that ſituation; for without this care it will require to be bent ſo as to offend the eye, for the purpoſe of putting the clock into beat, or otherwiſe will require a ſlit in it acroſs the centre, to admit of an eccentric adjuſtment, or ſome ſuch contrivance. When all the adjuſtments of the eſcapement are thus made, the pallet faces, if not jewelled, and alſo the pivots, muſt be hardened and finally dreſſed by the uſual ſucceſſive operations of poliſhing.

10. *Pendulum and Suſpenſion.* The precautions we have hitherto dictated, in our directions for the ſucceſſive operations in clock-making, have for their principal object the regular tranſmiſſion of a certain quantity of the maintaining power to the pendulum, in order to preſerve the arc of vibration unaltered, which is one of the two eſſential qualities of the going pendulum, on which the exact meaſurement of time depends; the other, which is an indiſpenſable quality of the pendulum, where great exactneſs is required, is that by which its length is preſerved unaltered in all the variations of temperature, as the centre of oſcillation regards the centre of ſuſpenſion. Theſe two properties of the pendulum, its conſtant arc, and conſtant length, conſtitute the excellence to which all the other parts of the mechaniſm are ſubſervient, and without which no clock will continue invariably

variably to indicate true time at all ſeaſons of the year, however exquiſite the workmanſhip of the movement and other parts. In an ordinary clock, the iron or ſteel rod of the pendulum is liable to conſiderable alternate expanſions and contractions, which render a compenſating contrivance neceſſary for pieces deſtined for aſtronomical purpoſes; or, otherwiſe, a deal or ebony rod is ſubſtituted for the metallic one, which natural ſubſtances, when of a ſtraight grain and gradually dried by age, are found to be much leſs liable to alteration in their length by changes of temperature, than iron or any other metal; their dimenſions, however, are a little altered by moiſture, which alteration renders them in our opinion objectionable.

In our half-ſeconds pendulum we propoſed to make uſe of a compenſation, in which the unequal and oppoſing expanſibilities of two different metals produce the deſired effect. It would, however, extend our preſent article to an improper length, if we entered here into the geometrical theory of the pendulum, or even if we detailed again the arrangement of the bars which conſtitute the mechaniſm of the compenſation propoſed; but under our article Pendulum, the reader will, we preſume, find the former omiſſion amply ſupplied; and the latter has been anticipated in our deſcriptions of Reid's and Brockbank's aſtronomical clocks. Reſpecting the ſhape and ſize of a requiſite bob or ball for the pendulum, we have already made our remarks under the word Bob, and therefore ſhall not repeat them here, particularly as we ſhall have occaſion to reſume the ſubject under the article Maintaining *Power;* it ſeems proper, notwithſtanding, to add a few words on the ſubject of the ſuſpenſion of the pendulum. Berthoud, the juſtly admired author of many French works on clock and watch-making, has affirmed (in conſequence of ſome of his experiments on the length of time that pendulums, differently ſuſpended, take in coming to the ſtate of quieſcence, after being moved the ſpace of a given angle from the line of direction), that what is called a knife-edge ſuſpenſion is preferable to that in which a piece of watch main-ſpring is uſed at the point of ſuſpenſion; we will not undertake to decide to which mode the preference is due, but adopt that which our Engliſh clock-makers, perhaps without a ſufficient compariſon of the two, have brought into general uſe. In ordinary clocks a ſlit is made in the moſt prominent part of the cock, into which the piece of watch-ſpring is inſerted, which carries a ſmall piece of braſs riveted to its extremity, by which the weight of the pendulum is ſuſpended on the cock, and a hole drilled through both the clock and braſs piece receives a pin to keep the pendulum in its ſituation; but this mode of ſuſpenſion is liable to two conſiderable objections:—firſt, if the pendulum ſpring happen not to coincide with a perpendicular line paſſing through the pivot-hole of the pallet's arbor, one ſemi-arc of vibration will be greater than the other, even after the bending or eccentric adjuſtment of the crutch has brought the clock into beat, for which imperfection this mode of ſuſpenſion affords no remedy; and ſecondly, the adjuſtment for time, as determined by the going of the clock, cannot be made without ſtopping the pendulum to ſcrew up the adjuſting ball at the bottom of the rod; to obviate theſe two evils, we might have ſuſpended our pendulum in a way which admits of both a lateral and longitudinal adjuſtment, without ſtopping the motion of the pendulum, according to the drawings contained in *Plate* XXVII., and deſcribed under the ſection of *Aſtronomical Clock*, by Meſſrs. Brockbanks; but for the ſake of variety, we propoſe to introduce a different mode of limiting the effective length of a pendulum, which mode is frequently uſed, but we believe has never before been publiſhed. The method we mean, is that which we have deſcribed under the head of *an eight-days portable clock*, contained in *Plates* XI. and XII.; from which deſcription, it is preſumed, the reader will already have apprehended all that is neceſſary to be underſtood relating to the mechaniſm, and its application to the regulation of the going pendulum.

11. *Dial-work.*—In the deſcription of the ſame eight-days clock which we have juſt referred to, has alſo been particularly explained the common dial-work of a clock, the different parts of which are ſo diſtinctly repreſented in *Plate* XII., that no further directions ſeem neceſſary in this place, eſpecially as we propoſe to give an ample account of the different methods of indicating time on the faces of clocks and watches, under the article Dial-*work.*

12. *Striking part.* As we have dwelt ſome time on the different ſucceſſive parts of the mechaniſm of the going-part of a clock, which are the moſt eſſential to be attended to, we hope to be excuſed, if we treat more generally, and claſs under one head what remains to be ſaid on the ſtriking part, which requires leſs of ſcience, and more of mere mechanical contrivance, than the parts we have hitherto treated of.

Neither do we mean to deſcribe over again here, the offices of the different parts of the ſtriking mechaniſm, but to point out the order in which the various conſtituent pieces ought to be ſucceſſively made, and to give our reaſons for their requiſite diſpoſition; leaving the mechanician and workman in poſſeſſion of their own mechanical reſources, to be applied in their own way.

The directions which we have given for the callipering and manipulation of the train in the going part of the clock, will equally apply to the wheels and pinions of the ſtriking part, and the ſpring box, D, *fig.* 1. *Plate* XI. together with the great wheel, F, and its fuſee, may be made preciſely in the ſame way as thoſe of the going part, C, and E, have been directed to be made; alſo the guard-gut muſt be ſimilar. To ſhew the manner in which the main-ſpring is coiled within the box, the lid or end piece is left out in our drawing. The numbers of teeth proper for the wheels and pinions of the ſtriking train, and alſo the number of pins in the pin-wheel, have been before explained; as alſo the ſtructure and poſition of the fly, hammer, and bell; which explanations therefore, need not be repeated.

When the dial-work is finiſhed, and the clock is meant to ſtrike the hours only, which is our ſuppoſition here, the warning-pin may be attached to the wheel which revolves in an hour, which we have elſewhere called the minute wheel, (ſee *fig.* 2, *Plate* XII.) becauſe it carries the minute hand as it revolves; or otherwiſe it may be put, as we have placed it, in the ſecond wheel of a ſimilar number of teeth, marked *g*, in *fig.* 1, of *Plate* XII. where it is better ſeen. The warning-piece, *t u v*, muſt revolve round the angular point, by means of a tube fitting nicely on a fixed ſtud, in ſuch a ſituation on the front plate of the frame, that the piece will not require much force, to be deducted from the maintaining power, to be moved from its ſtationary ſituation at the end of each hour; and that this may be the caſe, the tail-piece, *v*, ſhould lie at right angles with the tangent line, in which the warning pin is moving at the time of their contact; the bent end, *t*, muſt neceſſarily be at ſuch a diſtance from the centre of motion of the warning-piece, as the pin in wheel R, *fig.* 1, *Plate* XI. which it muſt fall in the way of demands. Alſo the hawk's-bill *p q r*, *fig.* 1, *Plate* XII. which is lifted by the bent end of the warning-piece, ſhould lie in a line,

p r,

p r, perpendicular to the tangent-line, in which the end of the warning piece moves at the inſtant of lifting, in order that the leaſt impreſſed force may detach the bill from the teeth of the ſubjacent rack; and that the hawk's-bill may have the mechanical advantage of a long lever, its centre of motion muſt be at the remote end *r*; likewiſe, in order that it may always move in the ſame plane, it muſt have alſo, like the warning-piece, a tube moving round a ſtud in the plate of the frame conſidered as its centre of motion. The weight and ſtrength of the materials of theſe two pieces, which are uſually of ſteel, ſhould be proportioned to the power of the main-ſpring which lifts them; for which reaſon, the lighter they are the better, provided they do not bend with the forces they have to ſuſtain as detents, when at reſt. The length of the gathering pallet, *s*, in the laſt named plate, muſt be guided by the ſtrength of the main-ſpring, as exerted at the arbor on which this pallet is placed, compared with that of the counter-ſpring, *o*, of the rack-tail: for if the latter is comparatively ſtrong, the pallet muſt neceſſarily be ſhort, to have power enough to gather up the rack; but the length of the tail of this pallet, depending on the diſtance that the catching pin, *m*, on the rack, is from the laſt tooth of the rack, may be optional; only it may be obſerved, that the longer the tail is, the more power it has to arreſt the motion of the ſtriking train, when the hour is ſtruck. It is of little importance, whether the gathering pallet be before or behind the bill of the hawk's-bill, provided they act clear of one another, and provided the rack have 12 notches, to be caught ſucceſſively by the pallet.

The ſize and ſhape of the rack, *m n*, depend on the diſtance of the centre wheel arbor from the gathering pallet, conjointly with the ſize of the ſnail *l*; when the quarters are not ſtruck, the ſnail is uſually attached to the 12-hours wheel, and revolves with it, as in our drawing; but it might with equal propriety be placed on a ſecond wheel, revolving in the ſame ſpace of time, as is the caſe in the clock with chimes, repreſented in *Plate* XVII. of *Horology*. The ſteps which form the notched ſpiral outline of the ſnail have their depth depending partly on the length of the tail-piece, *n*, of the rack, and partly on the ſize of the teeth of the rack; the diſtance from the outer to the inner end of the irregular ſpiral of the ſnail muſt be ſuch, and the length of the rack-tail ſo proportioned to the body of the rack, that the 12 teeth of the rack will only juſt paſs the gathering pallet, while the pin, in the extremity of the ſaid tail, moves down the ſtraight line that connects the two ends of the ſpiral, formed by the boundary of the ſnail; hence, ſuppoſing the rack previouſly made, the point for its centre of motion muſt be found ſuch, that the two conditions will be exactly fulfilled; but the beſt way is, to fix upon a point for the centre of motion firſt, and then to proportion the rack and ſnail to each other, for the aſſumed length of tail, from the ſaid centre of motion; the ſteps will aſcend by equal additions of height, if the teeth of the rack are equidiſtant. When the ſnail is deſigned, care muſt be taken, that each ſtep ſhall ſubtend exactly the twelfth part of a circle, or 30 degrees; the apparent increaſe in the ſize of the ſteps is not owing to any increaſe in the angles ſucceſſively ſubtended, but to the increaſe of the ſucceſſive radii of curvature: for as the wheel that carries the ſnail round revolves in 12 hours, every ſtep muſt correſpond to an hour's motion, otherwiſe the ſame hour might be ſtruck a ſecond time ſometimes, when a greater ſpace than the hour has elapſed, as indicated by the minute hand. The rack, like the warning-piece and hawk's-bill, is uſually made of ſteel; but the ſnail may be made of braſs, which is more eaſily cut by the file than ſteel. The bar for repetition, and the ſtrike or ſilent, may be added with little trouble, if deemed deſireable, but the account we have given of theſe parts before, when deſcribing a portable eight-days clock, will be deemed ſufficient by the generality of readers, and thoſe, who have been inſtructed in the art, will need no further direction from us reſpecting thoſe parts of the workmanſhip which are merely mechanical; for were we to enter into a detail of all the nick-nacks which have been introduced into the ſtriking part of a clock, we might write a whole quarto volume on the ſubject. Neither do we think it incumbent on us to enter minutely here into the particulars of the enamelling, ſilvering, &c. of the dial, or of the manufactory of the hands, and caſe, which are ſeparate departments: it may, however, be proper to obſerve, that ſome care is requiſite in making the pillars of the dial to be all of an equal length, that the plane of the dial may be exactly at right angles to the axes of the hands; otherwiſe they will approach the dial in ſome points of their reſpective revolutions more than in others, which will offend the eye of a ſpectator. It is a matter of very little importance whether the bell of the ſtriking part be fixed vertically or horizontally; this point is generally determined by the ſize and ſhape of the caſe that is fixed upon.

13. *Adjuſtment for Rate.* Suppoſe now our propoſed clock to be finiſhed, and fixed in its caſe, and this firmly attached to a ſolid wall, to avoid all caſual motion, that might be derived from the floor of the room in which it is placed, when trodden upon; ſuppoſe moreover, its poſition ſuch, that when the pendulum is put into motion, the two alternate excurſions are exactly ſimilar in extent and time, or, in other words, that the clock is in perfect beat; it then only remains to be brought to true mean time, ſolar or ſidereal, as its deſtination may be; if the latter is fixed upon, the adjuſtment for the length of the pendulum muſt be made from night to night ſucceſſively, till a ſtar, ſeen through a tranſit-inſtrument, ſhall be found to croſs the central thread of the eye-piece, exactly at the ſame hour, minute, and ſecond, for two or three ſucceſſive nights, which nicety of adjuſtment may be effected at any ſeaſon of the year, provided the compenſating mechaniſm be perfect; indeed an examination of the paſſage of the ſame ſtar, whatever it be, will detect the inaccuracy of the compenſation if there be any, provided the tranſit-inſtrument have its adjuſtments perfect. It is hardly neceſſary, perhaps, to add, that when any known ſtar is paſſing the middle thread of the field of view of a tranſit-inſtrument, properly ſet in the true meridian line, the ſidereal clock ought to be indicating the exact hour, minute, and ſecond, denoted by the ſaid ſtar's right aſcenſion for the year and day in queſtion. When ſolar or common time is intended to be indicated by the clock, which is the caſe for all civil purpoſes, the clock may be tried by a compariſon with a regulator previouſly adjuſted, or more accurately by ſucceſſive obſervations, taken of any of the heavenly bodies, as explained in ſome of the problems contained in our article CHRONOMETER.

If a tranſit-inſtrument is uſed as the inſtrument of obſervation, an allowance of $3^m\ 55^s.9$ muſt be made for each twenty four ſidereal hours, which is the quantity by which a ſolar day is longer than a ſidereal one, as has been explained under the article juſt referred to. It may ſave ſome time in making calculations for this purpoſe, if we ſubjoin a table computed for the ſervice of thoſe who wiſh their clocks to be properly regulated.

Table

Table for regulating Clocks or Watches.

Revolutions of the Stars.	Mean Solar Time corresponding.				Acceleration of the Stars in Solar Time.		
	d.	h.	m.	s.	h.	m.	s.
1	0	23	56	4.1	0	3	55.9
2	1	23	52	8.2	0	7	51.8

300	299	4	20	30.0	19	39	30.0
360	359	0	24	36.0	23	35	24.0
365	364	0	4	56.5	23	55	[illegible]
366	365	0	1	0.6	23	58	59.4

The application of the preceding table can hardly be mistaken, but, for the sake of illustration, we will suppose an example that shall include all the difficulties that are likely to occur in practice; let it, for instance, be required first to put the clock to mean solar time, when Spica Virginis is passing the meridian hair of a transit-instrument, on the evening of the 1st of May, 1807, and that, on the evening of the seventh succeeding day, the said clock being observed to be indicating $10^h\ 15^m\ 29^s$ at the moment, it be required to ascertain the daily loss or gain on an average of the said sidereal days? The work may be thus performed; *viz.*

R. A. of Spica Virginis for 1806 (Tab. III. Chronometer)	13^h	14^m	$59^s.29$
Annual variation for one year, add			3 .15
Ditto for four months, - do.			1 .05
	13	15	3 .49

Star's corrected R. A. for May 1, 1807	13^h	15^m	$3^s.49$
Sun's R. A. for noon of ditto, subtract	2	30	56 .3
Approx. solar time of star's passage	10	44	7 .19
Propor. part of $3^m\ 48^s.7$ (daily dif.) subtract		1	42 .03
True time of the star's passage to which the clock must be set	10	42	[illegible]
Seven days acceleration of the star from the Tab. subtract		27	31 .3
True mean solar time -	10	14	53 .86
Time by clock per supposition -	10	15	29
Amount of error in seven days	+0	0	35 .14

Hence the daily error, in excess in each sidereal day, is $= \frac{35^s.14}{7} = 5^s.02$, which was to be determined.

For the other methods of ascertaining the rate of a clock or watch, and for the manner of applying the equation of time, the reader is desired to consult the problems under the article Chronometer.

Clock-*movement* is a term in *Horology*, which sometimes implies a combination of wheels and pinions employed in the striking part of a clock, but most usually that succession of wheels and pinions which move one another, from the maintaining power to the pallets in the going part, and which are employed to transmit the force of that power in an equable but modified manner to the regulator, at the same time that they count and indicate the number of its vibrations in a given period of time. That these offices of the going part, to which we will confine ourselves principally, may be performed in a proper manner, it is requisite that the wheels and pinions of the movement should have their number of teeth properly calculated; that their diameters should be exactly proportioned to act in suitable pairs; that they should be properly callipered to make the pitch-line of each wheel coincide with that of its pinion; and that the teeth should be of a proper size and shape, to transmit the motion and force they have received, to the teeth acting with them in an uniform manner in every possible situation of the acting parts.

The three first of these requisites have already occupied a considerable portion of our attention under the article Clock-*making*, to which the reader is referred; and the fourth, which relates to the size and shape of the teeth, might have been properly deferred till we come to the word Tooth, had it not fallen so far into the alphabet; we shall therefore introduce the substance, appropriated to that word, in this place, that the subject may appear in as complete a state as our arrangement will admit, at an early period of our work.

Before we proceed to examine scientifically the requisites which ought to guide the practical construction of the teeth of wheels and pinions, it seems necessary that we should premise some observations on the principle by which a communication of motion and a transmission of force in general are effected in wheel-work.

In *Plate* III. *fig.* 1, of *Horology*, let A B be a lever, or rod without weight, moveable on C as a centre, and let W and *w*, supposed to be two bodies with weight, have their masses so proportioned to each other, that the mass *w* may be to the distance C A, as the mass W is to C B; or, in other words, if the mass *w*, multiplied by its distance from the centre of motion,

motion, B C, give a product, or momentum, equal to the product of the mass W multiplied by its distance C A; then the two bodies, *w* and W, will remain in equilibrio in any situation, A B, or *a b* of the free lever; but if we suppose the two bodies to have equal masses, or, which is the same thing, equal weights, it is equally evident, that the body, *w*, would preponderate in consequence of its greater distance from the centre of motion, which we will suppose to be three times as great as that of W, and its velocity would, in this case, be three times that of W; consequently it would require an opposing force, three times as much as W would require, to arrest its motion; but if W has its mass or weight increased three times, the distances remaining unaltered, the opposing forces, becoming similar, would then arrest one another, and produce an equilibrium.

The same effects would follow if the threads of suspension were not left free at the ends of the lever, but were folded round the circumferences of two circles, described round the common centre, C, with their respective radii, C A and C B, *fig.* 2; in this case, also, the smaller the circumference of the dark circle is, the greater must be the suspended weight to preserve the equilibrium of the two circles, and *vice versâ*, the ratio being constantly reciprocal.

Let us suppose, now, *fig.* 1 placed contiguous to *fig.* 2, with the large circle of one converted into the portion of a wheel, and the small one of the other into a pinion, as in *fig.* 3, and let us see what will be the consequence, when the teeth are connected and the weights, W and *w*, applied as before; if we suppose the materials of which the portion of the wheel and the pinion are made, to be without weight, an equilibrium will still take place; but remove the small weight *w*, and what will then be the consequence? Why, the pinion D will be impelled at a mean rate, in a direction contrary to that of wheel B, with a force equal to the weight of the small mass, *w*, or, as we have assumed, equal to one third of the large mass, W, which may now be called the maintaining power. But when a tooth of the pinion moves with only one third of the force of W, applied at the point, A, of the wheel, which is at a distance from the centre, C, equal to the radius of the pinion, it moves with the velocity of point B of the wheel, tooth for tooth, and therefore the pinion makes three revolutions for the wheel's one, supposing their numbers to be respectively 16 and 48, as their radii; hence 3, the acquired angular velocity of the pinion's circumference, multiplied by $\frac{1}{3}$, its diminished force, makes the momentum unity, which will also represent the momentum of the maintaining power in motion, *viz.* force *3* multiplied by $\frac{1}{3}$ comparative velocity. Again, let us suppose the pinion, D, actuated by a body, *w*, equal to $\frac{1}{3}$ of the weight of W, and disregard its velocity for the present, the portion of another wheel, E, attached to it by the lever E D, will have its motion contemporary with it; but, by the same mode of reasoning, the velocity of the point E will be increased to three times that of the pitch-line of the pinion, as before was the case with the wheel B, compared with the point A; but its force will be diminished in the same ratio: that is, the velocity will be $3 \times 3 = 9$, and the force, disregarding friction, &c. will be $\frac{1}{3} \times \frac{1}{3} = \frac{1}{9}$; but $\frac{1}{9}$, the force, multiplied by 9, the velocity, will still be unity as before; accordingly, a small body, F, having one-ninth part of the weight of W, the maintaining power, carried over a small fixed pulley, G, will be sufficient to preserve the equilibrium with respect to the maintaining power, when the second body, *w*, is removed. If an additional wheel and pinion were added to the above, and were supposed to have the same dimensions, the velocity produced at the pitch-line of this third wheel would be $9 \times 3 = 27$, and the diminished force, on our former supposition of no friction or opposing force, would be $\frac{1}{27}$ only of the maintaining power. In this illustration of the principle by which an increase of velocity, and a corresponding decrease of power, accompany a communication of motion in alternate directions in wheel-work, the teeth may be considered as the remote ends of so many levers, which have their fulcra at the centres of the wheels and pinions respectively, as in *fig.* 4; and it is easy to see, that an accumulation of velocity, accompanied by a corresponding diminution of force, may be produced in any machine where the wheels drive the pinions, as is the case in clock-movements, to such an extent, even where the ratio of the wheel to the pinion is 3 : 1 only, that the friction of the acting parts, together with the resistance of the air opposed to the moving parts, may become a complete counterpoise to the maintaining power. In higher ratios of 12 : 1, 8 : 1, &c. which are used in clocks, the number of wheels and pinions, to produce such an equilibrium, would not require many pairs beyond what an ordinary clock has for its movement. If, however, the pinions had been the drivers instead of the wheels, the reverse of what we have stated would have taken place; the velocity would have decreased, and the force applied have been augmented in the same ratio we have explained, which is the case in cranes, and other engines for raising heavy bodies. Hence, if the movement of a clock were composed of strong wheels and pinions with thick arbors, and had the power applied at the balance-wheel, which may be called the top of the movement, the barrel of an eight days clock having a thick cord coiled round it, would raise a very ponderous body, and become no mean engine for lifting weights, surpassing the ordinary efforts of man's natural strength.

A slight consideration of what we have here advanced, will suffice to convey an idea to any one, who has not previously considered the subject, how admirably well adapted for the purposes of a clock-movement this property in dynamics is, by which an increase of velocity is always accompanied by a proportionate abatement of force; for by means of it, the maintaining power, however large, may be so economically portioned out in minute quantities, sufficient only to compensate the loss of motion which the pendulum or balance sustains, at each vibration, that it may be made to last for many days, or even weeks, before it is exhausted by the great number of successive minute deductions, which are made at periodical intervals; at the same time, certain wheels and pinions, by their numbers and due arrangement, divide and subdivide, by means of hands and divided circles, the sexagesimal portions of each hour, denominated minutes, and also of each minute by the name of seconds. The various offices of communicating motion, of increasing its velocity as at first produced, of diminishing the original force of the maintaining power, of dividing, subdividing, counting, and indicating the hours, minutes, and seconds, all performed by the simple contrivance of a clock-movement, or watch-movement, in conjunction with the regulator, we hesitate not to affirm, when duly considered, exhibit one of the most striking instances of human ingenuity. The experiments of the philosopher, the calculations of the mathematician, and the persevering skill of the mechanist, have combined to produce ultimately this admirable piece of mechanism, of which we hardly know which most to admire, the simplicity of the construction, or the complexity of the various offices, constantly and most correctly performed.

As a further illustration of this fundamental part of our subject, we will here introduce the reader again to the calliper of our proposed half-seconds clock, (see CLOCK-*making*) where we will suppose the centres of the wheels and pinions arranged in a straight line, as seen in *fig.* 4, of *Plate* III. We will suppose the main-spring, or power, pulling with a force, at the point P of the great wheel A, equal to the weight of a body, W, of three pounds; then because this wheel has 96 teeth, and actuates a pinion, *a*, of 8 leaves, their numbers of teeth being directly to each other as their radii, which are represented as levers acting together, with their fulcra at the respective centres, the velocity at the circumference of the wheel will be communicated to the circumference of its pinion *a*, which therefore will make $\frac{96}{8}$, or 12 revolutions, during the time that the wheel makes one; hence if the great wheel be assumed to revolve once in 12 hours, as we proposed, the centre pinion *a*, together with its wheel B, will revolve in one hour, and its arbor will be proper for the hand to indicate minutes on a circle of 60 on the clock face; but it must be observed, that the velocity is not increased 12 times, as it respects the point P, where the maintaining power is applied, nor is the force diminished in the same ratio as it regards that point; but, to make the calculation more simple, we will consider the distance of P, from the centre of A, equal to $\frac{1}{12}$ of the radius of wheel A, which is the radius of pinion *a*, and correct the conclusion drawn from such a supposition afterwards: the pinion *a* then, we say, has its velocity at the pitch-line, or its number of revolutions equal to 12, and its force equal to $\frac{1}{12}$; in the next place, the radius of a pinion *a*, is to the radius of the concentric and contemporary wheel B, as 8 : 64, and $\frac{64}{8} = 8$; the circumference of this centre wheel, therefore, will move with a velocity equal to 12×8, or 96, and with a force only of $\frac{1}{96}$; both which will be imparted to the pitch-line of the pinion *b*, of 8 leaves; again, the radius of the latter pinion *b*, is to the radius of its concentric and contemporary wheel C, as 8 : 60; but $\frac{60}{8}$ is a fraction, the value of which is $7\frac{1}{2}$; and $96 \times 7\frac{1}{2}$ therefore make 720 to express the velocity, or number of revolutions of pinion *c*, actuated by the wheel C; and $\frac{1}{720}$ will express the force, or fractional part of three pounds, the quantity assumed for the maintaining power, which is equal to 24 grains of troy weight. We have now found, that while the wheel A is making one revolution, the last pinion *c* will make 720, and that 24 grains troy, suspended by a small pulley over the pitch-line of pinion *c*, and attached to it, will balance three pounds of the same species of weight, suspended at $\frac{1}{12}$ of the radius from the centre of the great wheel, if we disregard the effects of friction. Let us examine the consequence of these calculations as they regard our arrangement of the calliper: the pinion *c*, we have seen, revolves in $\frac{1}{720}$ of 12 hours, according to our original assumption of A revolving in 12 hours; but in twelve hours there are just 720 minutes; one revolution consequently of the last pinion *c*, is performed in exactly one minute; its arbor will therefore be proper for the axis of the seconds hand, which goes round its circle of 60 in this time: but the maintaining power, W, is not actually suspended at $\frac{1}{12}$ of the radius of wheel A, according to our supposition when we calculated, consequently the result, as it relates to the modified force at the pitch-line of pinion *c*, requires yet to be corrected, or somehow compensated; this is done by making the radius of the swing or balance wheel D, equal to the distance of P from the centre of A, in which case, the calculated velocity and force at any point in the circumference of D will be in the same proportion to what those of the maintaining power suspended at P are, as the velocity and force at the pitch-line of pinion *c* would have been, if the same maintaining power had been actually suspended $\frac{1}{12}$ of the radius of A, from its centre; the body W of 24 grains therefore attached to the circumference of wheel D, and carried over the small pulley above it, will balance three pounds, suspended at the point P, of the great wheel, if, as before, we disregard friction; and the push made, in any direction, against the pallet face, will be equal to a force of 24 grains, acting in the same direction: the same result would also have accrued, if the body W had been suspended at the circumference of wheel A, provided the swing-wheel had been of the same radius; but, supposing the body W to remain at P, and the swing-wheel D made equal to the great wheel, then the velocity of the former would have been increased, and its force diminished, in the proportion of the diameter of the swing-wheel to the diameter of the barrel, by which we suppose the body W to be suspended at P: in this case, the small dotted body, *x*, suspended at *y*, at a distance equal to the radius of wheel A, would have been sufficient to keep the body W in equilibrio.

The pendulum proposed to be adopted, being a half seconds pendulum, the swing-wheel must have 60 teeth, in order that one tooth may escape the pallets at every second vibration, which therefore becomes a proper regulator for our present movement.

When the whole movement is previously given in any clock, and we want to ascertain the relative revolutions of the first and last wheels, a little consideration of what we have said will show, that the product of all the wheels, divided by the product of all the pinions at one operation, will give the result at once thus, $\frac{96}{8} \times \frac{64}{8} \times \frac{60}{8} = \frac{368640}{512} = 720$, as before.

Also, when the relative forces of the maintaining power, at the barrel, and at the end of a tooth of the pallet-wheel are thus ascertained, this calculated force must be altered, inasmuch as the pallet-wheel has its diameter greater or less than that of the barrel, accordingly as we have shown above. When a spring and fusee are used, the power of the spring may be ascertained either by the instrument of adjustment used as a lever with a sliding weight, or, what will be less equivocal, a barrel may be attached to the square of the fusee arbor, when the spring is adjusted, and then a heavy body suspended by it in a scale to admit of weights of adjustment, which barrel and weights may be substituted for the spring and fusee in the calculation, first of the whole force applied as a maintaining power, and then of its modification at the face of the pallets.

If we were to take the opposing force of friction into our calculation, we should find the problem extremely complicated; for there are not only various causes of friction in a movement, such as that caused by the action of the teeth, and in the pivot-holes, &c.; but the continual variation of the quantum of friction, arising from the destruction of the rubbing parts, the thickening of the oil usually applied, and the admission of dust, is such, that no regular and constant data can be obtained whereon to ground such a calculation as would prove serviceable. The readiest, and perhaps best, practical way of ascertaining how much of the maintaining power is expended in friction, is really to suspend such small weight by a tooth of the swing-wheel, as will balance the maintaining power, and compare this with the requisite force obtained by calculation; the difference will give the collective quantum of friction, at the time of the experiment, in the whole movement.

Friction, however, is not the only obstacle to the maintaining

ing power in the works of a clock in motion; the tranfmiffion of force is not conftant, but effected at fuch equi-diftant intervals of time, as depend on the vibrations; for inftance, in our half-feconds piece, the wheels and pinions are put into motion, and ftopped again alternately 60, and where there is recoil 120 times in each minute; hence the inertia of the matter compofing the wheel-work is as often to be overcome as the arrefted motion is re-produced, and if the wheels are not made very light at the upper end of the train, where the force is greatly reduced, a very confiderable portion of the calculated force will be employed in moving the works from a ftate of reft, at every vibration. We prefume it is on this account, more than on account of friction, that the workmen have found it neceffary to diminifh the wheels, and to reduce their weight, as much as is confiftent with ftrength, accordingly as the train afcends. To overcome the obftacles to the due effect of the maintaining power, arifing from friction, and the inertia of the wheels and pinions, more force is ufually given to it than would otherwife be neceffary, and the requifite addition, over what calculation gives, muft in every inftance depend upon tentative adjuftments of the maintaining power to the momentum of the regulator, fo as to produce the due excurfion of the pendulum or balance beyond the efcapement angle. In fome delicate machines for keeping true time, the pivots of the arbors are made to reft on friction rollers, or otherwife, are bufhed with fome of the precious ftones that take a high polifh, which expenfive additions admit of the maintaining power being fmall in comparifon with the momentum of the regulator; which circumftance, when the regulator is rendered unchangeable by fome compenfating mechanifm, is beft calculated to preferve the angle of vibration alfo unchanged, provided the maintaining power remain uniformly the fame; and even if fome flight alterations of force fhould arife out of an imperfect adjuftment of the fufee, where a fpring is ufed, the great controul of the regulator would, under fuch circumftances, reftrain the effects of the flight irregularities of the impulfes on the pallets.

Hitherto we have confidered the action of the wheel with its pinion, or what the French call *engrenage*, to be fo perfect, that the velocity and force, at the circumference of every wheel, is truly and conftantly imparted to its refpective pinion; which is fuppofing not only the wheel-work to be proportioned and callipered with the utmoft exactnefs, but alfo their teeth fhaped in the beft manner. There are, however, three very common caufes of bad action; firftly, whenever the wheel is too fmall for the pinion, though ever fo well callipered, its teeth will pitch againft the ends of the pinion's leaves, and require more then ordinary force to be confumed in their difengagement; fecondly, when the wheel is too large, it will impart to the pinion too much velocity during the action, and part of the force will be expended in the drop that will take place before the action commences againft each following leaf of the pinion, after it has ceafed to act with the leading leaf; and thirdly, if the curve of the tooth be ill formed, the tranfmitted force will, in fome fituations, exceed, and in others fall fhort of a mean force; in all thefe cafes the varied intenfities of the tranfmitted force will confiderably affect the ifochronifm of the regulator with any of the ordinary efcapements. Of the two firft of thefe caufes of bad action, we have pointed out the remedy, when we treated of the proper method of proportioning and callipering a movement, under the word CLOCK-*making*; the third, which is of the utmoft importance, not only in clock-work, but in wheel-work of every defcription, prefents itfelf now for difcuffion.

In *fig.* 5 of *Plate* III., let us fuppofe b C A and $b\,c\,a$ two bent levers, refpectively moveable on the points C and c, as their centres, and let us conceive that the parts, C A and $c\ a$, which are in the direction c C of the line of the centres of motion, be unchangeable in length, and be loaded with their refpective weights W and w; but that the parts, b C and $b\ c$, be variable in length, fo that in any fituation their extremities may meet and act reciprocally on each other; we affirm that the fame weights W and w, which will keep the two variable levers in equilibrio at the point P, in the line of the centres, will alfo keep them in equilibrio when their ends reft againft each other at any other point, b, in the circumference of a circle, of which c P, or C P, is the diameter.

Demonftration. Let $b\ d$, the fhort line perpendicular to b C, which may reprefent the fhort arc made in an inftant by the lever b C, turning on the centre C, exprefs the abfolute force of the weight W, acting at the extremity of the lever; and let this abfolute force be decompofed into two others, $b\ e$ and $b\ f$, the former of which, $b\ e$, may be perpendicular to $c\ b$, in the direction of P b, the angle at b being a right angle, by reafon of its being formed at the circumference by two chords from oppofite ends of the diameter, and the latter, $b\ f$, may be parallel to the line b C; it is evident that $b\ e$ expreffes that portion of the force $b\ d$, which is employed in moving the point, b, of the lever $c\ b$, from b towards g, and, confequently, in making the lever, $c\ b$, revolve, whilft the other portion, $b\ f$, expreffes that part of the force, $b\ d$, which has a tendency to pufh the point b towards C; but C is a fixed refifting point, which therefore deftroys this part of the decompofed force: we fay, likewife, that $b\ d$ expreffes the abfolute force exerted at the end, b, of the bent lever, $a\ c\ b$, by the weight w, to oppofe the revolution of the point, b, round its centre, c; for, becaufe the right line, A W, is perpendicular to C A, and alfo $b\ d$ to b C, the weight, W, is to the force, $b\ d$, as the line, b C, is to C A; but in taking C B perpendicularly to the line, b P, prolonged, the like triangles, $d\ b\ e$, and C b B, give $b\ d : b\ e$: C B : C b, therefore, by multiplying, W : $b\ e$ :: C B : C A: now let the abfolute force with which the weight, w, urges the point, b, in a direction oppofite to $b\ g$, be called x, and we fhall have $w : x :: c\ b : c\ a$, or, on account of the fimilarity of the triangles, $c\ b$ P, C B P, as C B to C P; but on the fuppofition that the two weights, w and W, will balance each other, when their forces are exerted reciprocally at the point P, on account of the equality of the levers, $c\ a$, c P, the weight, w, may be fuppofed to be fufpended at the point P; it will be then as W : w :: C P : C A; likewife, by multiplying, W : x :: C B : C A; but we have juft proved that W : eb :: C B : C A, therefore $e\ b = x$; hence there will be an equilibrium, when the force, $e\ b$, is equal to the force with which the point, b, is urged to revolve by the weight W. It is equally demonftrable, that an equilibrium will take place between the two levers when their point of contact falls in any other part of the circumference of the circle, $c\,b$ P; and alfo, that an equilibrium will not take place if fuch point of contact fall either within or without the circumference of the faid circle. Vide Berthoud's "Effai fur l'Horlogerie," tom. i. p. 41.

Corollary. From the preceding demonftration an inference is deducible, of the utmoft importance in wheel-work; namely, if we fuppofe the point b to be always in the circumference of $c\,b$ P, while the lever b C A impels the lever $b\,c\,a$, the circles H K and $h\ k$ defcribed from the centres of motion C and c, and touching one another at P, when attached each to its own lever, will move with the fame force and the fame velocity.

For 1ft. Let F and f be the refpective forces with which

which the circumferences of the circles H K and hk are urged, and we shall have $bd : F :: CP : Cb$, and $f : be :: cb : ch$ or cP; but we have seen above that $be : bd :: Cb : CB$, therefore $f : F :: CP \times cb : cP \times CB$; but the similar triangles cbP and CBP give $cP : CP :: cb : CB$; hence $cP \times CB = CP \times cb$, therefore $f = F$; consequently, if the circle H K be moved by any force uniformly, the circle hk will also be moved uniformly.

2dly. Whatever may be the velocity of the point b, of the lever ACb, that which it will communicate to the lever bca, in the direction be, perpendicular to the point of contact, will be the same as that of point b; that is, if we demit the perpendicular dg, the velocity in the direction bd, being represented by bd, the velocity in the direction be will be represented by bg. If then V be the velocity of the circumference of the circle, or wheel, H K, and v that of the smaller circle, or pinion hk, it is evident that $V : bd :: CP : Cb$, likewise, that $bg : v :: cb : ch$; also, the like triangles, bdg, and CbB, give $bd : bg :: Cb : CB$; therefore, $V : v :: CP \times cb : cP \times CB$; but these two last products we have seen are equal, therefore $v = V$.

By a similar reasoning it is equally demonstrable, that neither the force nor velocity of the wheel would be equally communicated to the pinion, nor those of the pinion to the wheel, if the point of action were situated either within or without the semi-circle cbP.

To apply the preceding corollary to our present purpose, of effecting an equable communication of force and velocity in wheel-work, let us conceive the variable levers ACb, and acb, in *fig.* 1, *Plate* IV. so circumstanced, that their remote points, b, meet at P, and that the points H and h, of the wheel H K, and pinion hk, be also in contact at P; let the wheel now move through five successive portions, $H\alpha$, $\alpha\beta$, $\beta\gamma$, $\gamma\delta$, and δP, successively, and conceive it to drive the pinion hk, by simple contact; in this case, the pinion will move in like manner, through similar arcs $h\alpha'$, $\alpha'\beta'$, $\beta'\gamma'$, $\gamma'\delta'$ and $\delta' P$, and at each of the successive points of contact, $\alpha\alpha'$, $\beta\beta'$, $\gamma\gamma'$, &c. the respective lengths of the levers, in order to meet in the semi-circle cbP, will be $AC1$ and $ac1$, $AC2$ and $ac2$, $AC3$ and $ac3$, $AC4$ and $ac4$; and, lastly, ACb and acb, continually varying: hence we may conceive a curve, Hb, such, that some point of the variable lever ach, between b and h, shall always rest on it in every successive situation of the wheel and pinion, beginning at h, and ending at b; if now we suppose the curve H, on which the variable end of the lever cbh rests, to be attached to the wheel H K, and to be brought back into its original situation P, and also ch to be coincident with cP, it is evident that, though the wheel and pinion were not so in contact as to impel one another, yet if the wheel were to be moved uniformly as before, the curve-piece attached to it would drive the lever cbh before it in such a manner, as to effect a constant variation in its length, but whether such motion of the pinion occasioned by the attached straight lever, when urged by the curve-piece Hb, will or will not be uniform, depends entirely on the nature of the curve which we have not yet established. Let us examine the figure a little more closely. The arcs P H, of the wheel, and Ph of the pinion, we have assumed to be equal in length, though one contains double the number of degrees as the other, by reason of having only half its radius; but the semicircle, cbP, is described from only half the radius of the pinion; consequently the dotted lines, $c1$, $c2$, $c3$, &c. which measure degrees, by being prolonged, on the circumference of the pinion, measure double degrees on the semi-circle, cbP, by reason of their meeting at the end of the diameter, instead of at the centre; therefore the arc Pb, is also equal in length to either of the others, P H, and Pb. These considerations will enable us to determine the requisite curve, thus; transfer the divisions, $H\alpha$, $H\beta$, &c. from P, back towards K; and through the intersections 1, 2, 3, 4, b, of the small semi-circle, cbP, draw parallel arcs, 11′, 22′, &c. in dotted curves from C, as a centre; which extents will be the successive acting lengths of the radius of wheel H K, in the successive situations, as it revolves from P to H; also the small extents P 1, P 2, P 3, &c. will be so many radii of curvature applied successively from the different points of division; for instance, P 1, applied to the first point below P, will intersect the innermost dotted arc at 1′; P 2, from the second point in P K, will intersect the second dotted curve line at 2′; P 3, from the third point, will intersect the third dotted line at 3′; P 4 at 4′; and, lastly, P 6, at 6′; and if the interstices of the curve so formed be completed, it will have the peculiar property of driving the straight line, bh, and its pinion, with an equable force, and an equable velocity, provided the wheel H K, to which it is attached, move equably; for the acting point will always be found in the semi-circle cbP, which is fulfilling the condition of the problem; also, reversing the motion, the straight line, bh, will drive the curve, b H, and its wheel, back again, with an equable force and velocity, as though the pinion drove the wheel by contact. We have here supposed the curve piece attached to the wheel, and driving the pinion, but the same projection, or rather the same mode of projecting the curve, will apply when the pinion has the curve, and is the driver according to the representation given in *fig.* 2, of *Plate* IV. which is the reverse of *fig.* 1. We have also hitherto supposed, that a wheel or pinion moves always in the same direction; but as it is frequently required in wheel-work, that the works should turn both backward and forward, it is necessary to have a counter-curve on the following part of the tooth, which in its turn may occasionally be the leading part; the same geometrical process will give this reverse curve, which must necessarily begin at the distance from the other of the whole breadth of the tooth; in our drawing, we have given the tooth equal to four divisions, in order to show more clearly the process of describing it, but in ordinary works, particularly in clock movements, the strength of the tooth is too small to admit of being described and demonstrated in this way; we have notwithstanding thought it our indispensable duty to investigate, and lay before the reader, the fundamental principle on which the proper shape of a tooth depends. According to the preceding investigation, the curved portion of one tooth, it will be seen, must always drive a straight edge of the other, and *vice versâ;* also a line drawn from the point of action to the primitive circles, or pitch line, where it is intersected by a line joining the centres, will be always perpendicular to both the straight line and the curve.

Here the reader will naturally be led to ask, what is the precise nature of the curve we have determined? and what name shall we give it? A little reflection on its property and delineation will soon convince the geometrician that it is an epicycloid, or rather a portion of an epicycloid, for the generation of which the wheel constitutes the base, and a circle, equal in diameter to the radius of the pinion, the generating circle. Camus in his "Cours de Mathématiques," Liv. x. and xi. has investigated the epicycloid, as it affords a rule for the formation of teeth in wheel-work, which portion of the work has lately been translated into English, but the translator has added some practical directions respecting the shape of a tooth, taken from "Imison's Elements of Science and Art," the principle of which we think it necessary here to correct, at the same

ſame time that we avail ourſelves of the elucidation of our ſubject which Camus's maſterly treatment of it affords.

In *fig.* 3, of *Plate* IV. let H K repreſent a portion of the ſame wheel which is repreſented by the ſame letters in *fig.* 1, and let the epicycloidal curve, H 2′ 4′ 6′, be deſcribed in the uſual way by a fixed point in the circumference of a ſmall circle, with a radius equal to that of the ſemicircle, *c b* P, in *fig.* 1, coming in contact with the circle H K, and thereby effecting a revolution; then it is evident that the epicycloidal curve in our preſent diagram is preciſely the ſame as the curve P 1′ 2′ 3′ 4′, &c. in *fig.* 1, which ſimilarity proves the latter to be alſo epicycloidal; for the chords 2 2′, 4 4′, &c. in *fig.* 3, are preciſely the ſame as P 2, P 4, &c. with which the points 2′, 4′, &c. are deſcribed in the curve P 1′ 2′ 3′, &c., in *fig.* 1; and in *fig.* 3, the arcs, 2 2′, and 4 4′, &c. are reſpectively equal to 2 H, 4 H, &c. of the ſame *fig.* in the ſame way that P δ′, P γ′, &c. are reſpectively equal to P δ, P γ, &c. in *fig.* 1. This epicycloidal curve, P 1′ 2′ 3′ 4′ *b*′, in *fig.* 1, or H 2′ 4′ 6′, in *fig.* 3, is of the kind called exterior, by reaſon of the generating circle revolving round the outſide of the baſe H K; but if it were made to revolve by a ſimilar contact with the interior ſide of a circle, the generated curve would be of a different ſhape, and would be denominated an interior epicycloid. In the particular caſe where the generating circle has its diameter, exactly equal to the radius of the circle which conſtitutes the baſe, the line generated by a fixed point in the circumference of this generating circle will not be a curve, but an exact ſtraight line paſſing through the centre of the circle which is made the baſe: thus in the lower part of *fig.* 3, if we conceive the fixed point, in the generating circle, for deſcribing the line required, to be at *a*, a point in the circumference of the baſe, *a d e*, and the generating circle to move forwards to the points *d* and *e* ſucceſſively, it is demonſtrable that the ſaid fixed point, *a*, will be found ſucceſſively at *b* and *c*, and will conſequently deſcribe the ſtraight line or radius, *a b c*, in the ſame time that the generating circle revolves down one quadrant, *a d e*, of the circle conſtituting the baſe; this conſequence muſt follow from the conſideration that the arc, *d b*, is equal to the arc, *d a*, and that the ſemi-circle, *e c*, is equal to the quadrant, *e d a*, according to our aſſumption of the diameter of the ſmaller circle being exactly equal to the radius of the larger.

With theſe demonſtrable truths in our recollection let us now turn to *fig.* 4, and ſee how both the exterior and interior epicycloids are concerned in the formation of an epicycloidal tooth, or tooth that has the property of tranſmitting both the force and velocity it has received without alteration to its fellow-tooth, when it is alſo ſhaped according to the ſame principle: if we ſuppoſe the portion of a circle, H K, to drive the ſmall generating circle, *c b* P, equably by ſimple contact at the point, P, the fixed point *b* will deſcribe the portion, H *b*, of an exterior epicycloid on the plane of H K, extended, which portion we will ſuppoſe to be one ſide of a tooth attached to H K, to which curve the line P *b* is always perpendicular; again, if we ſuppoſe not only the ſaid generating circle *c b* P, but alſo at the ſame time the circle *k h*, to revolve, by means of a ſimilar contact with H K at the point P, then the inner or generating circle, *c b* P, will make two revolutions, while the outer one, *k h*, makes only one; the conſequence reſulting from ſuch a combination will be the ſame, as though the generating circle, *c b* P, moved only once round within the circle, *k h*, conſidered as ſtationary, that is, the circle *k h* becomes the baſe to the generating circle, and the deſcribing point *b* ſo circumſtanced will trace on the plane of circle *k h*, the ſtraight line or interior epicycloid, *b b c*, which is the radius to the circle conſtituting the baſe in this caſe. Hence if we conceive the points *b*, *h*, and H, to coincide at H, for the original poſition of the three circles, and alſo of the tracer *b*, it is eaſy to comprehend, that, if a ſlit were cut in the plane of the circle *k h*, in the direction of the radius *c h*, ſuch as would juſt admit the tracer to paſs through it, provided the great circle, H K, communicates its motion equably to the other two by contact at the point P, the tracer will paſs along the ſlit, conſidered as an interior epicycloid, and at the ſame time will deſcribe an exterior epicycloid on the plane beneath both the circles, *c b* P, and *k h*. A ſmall inſtrument might readily be made to prove practically that the reſult we have here pointed out would follow from this arrangement of three circular metallic plates kept in their places by a ſuitable frame. But this is not all; if the curve H *b* be made to form a part of the circle H K, conſidered as a wheel, and the point, P, of contact be removed a very ſmall diſtance from the two circles, ſo as not to touch them, the points, *b*, *h*, and H, may be again brought into their original coincident ſtate, either by puſhing the tracer, attached to the extremity of the generating ſmall circle, againſt the edge of the epicycloidal curve, or otherwiſe by ſubſtituting a ſtraight lever in the place of the ſlit, as a radius of the circle *k h*, and by preſſing it, inſtead of the tracer, againſt the ſaid curve; in either caſe an equable motion will be communicated to the great circle or wheel, K H, as well as though it had been actuated at the point of contact, P: nay, moving the tracer back from *h*, while in the ſlit at P, would give an equable motion to all the three circles: alſo reciprocally, the curve H *b*, by preſſing againſt the tracer, while the wheel H K is in motion, will give an uniform motion to the generating circle, *c b* P; or otherwiſe it will uniformly drive the larger circle *k h*, by preſſing againſt its radial lever; in either caſe the motion will be as equable as though communication were to take place by mere contact, or by teeth infinitely ſmall, at the point P.

This view of the ſubject, it is preſumed, will afford the reader a full and clear elucidation of the application of the exterior and interior epicycloidal curves to the formation of teeth in wheel-work, and, at the ſame time, eſtabliſh an eſſential difference, which has been overlooked hitherto in practice, between the curve generated by a circle equal to one of the acting wheels or pinions, and the curve generated by a circle equal in diameter to only *half* of one of the acting wheels or pinions, the correſponding wheel or pinion being in both caſes taken of its full geometrical diameter as the baſe of generation. The tranſlator of a part of Camus, and the editor of "Imiſon's Elements of Science and Art," have poſitively though erroneouſly aſſerted that the generating circle ſhould in all caſes of wheels and pinions be equal to the fellow of the wheel on which the curve is to be deſcribed, in which opinion ſome very reſpectable mechanicians agree; but others, on the contrary, aſſert, with equal confidence, and more truth, that the ſaid generating circle ſhould have its diameter equal to only one half of the diameter of the ſaid fellow. (See Camus, Dr. Young's Syllabus, and Brewſter's Edit. of Ferguſon's Select Exer. &c.) A careful examination of Camus's demonſtrations would of itſelf have reconciled the diſagreeing parties, which we truſt a due attention to our elucidation, by means of the tracer and radial lever, will not fail to effect. The fact is, that, where pins like our tracer, or ſpindles are uſed for teeth in any wheel or lantern, as is frequently the caſe in large works, the generating circle muſt be equal in diameter to the diameter of the acting wheel or lantern which it repreſents, in order to trace the epicycloidal

teeth

teeth of its fellow; but in clock-movements, and in all other inftances in wheel-work where both the wheels and pinions have the epicycloidal formation, the generating circle muft be only one half in diameter to what it is required when lanterns are ufed, for in this cafe, which is what is moft frequent, the interior and exterior epicycloids impel each other alternately, the former being a portion of the radial lever, and the latter a portion of the epicycloidal curve: thus, if a pin were attached to the extremity of the generating circle cbP, and a radial lever to the plane of the circle, kh, of twice its diameter, they would be alike driven by the epicycloidal tooth, H b, of the driving great wheel, HK. Hence the fhape of the tooth of the driven wheel or pinion will always determine whether the curve of a tooth in the driver muft be defcribed by a circle of the full or half fize ufed as a generating circle, neither of which, it appears, will apply exclufively in all cafes. It may be remarked, however, here, that the beginning of the curve, or that part which is formed on the end of a tooth, will in practice be, as nearly as may be, the fame whichever of the two generating circles be made ufe of, particularly if the teeth to be formed are fmall; for in *fig.* 1, it will make little difference whether P 1 and P 2, or P δ and P γ, be taken as fucceffive extents for defcribing the curve P 1′, 2′, &c.; but if Ph were taken inftead of Pb, the difference at b', the remote end of the curve generated, would be confiderable. Hence the argument in favour of the erroneous principle, adduced from the trial of feven years wear without repair, by the tranflator of Camus, is without weight, and proves only that a convenient approximation to the truth may fometimes be fubftituted for the truth itfelf in practice; as the fmall circular arcs of a pendulum are fubftituted for cycloidal arcs, to which they are very fimilar at the loweft point; but where the truth itfelf is attainable by equally fimple means, approximations ought to be inadmiffible.

Our theory, it will be obferved, hitherto fuppofes that the whole tooth of the driving wheel or pinion be formed by interfecting portions of an exterior epicycloid, and that the whole tooth of the driven wheel or pinion be formed like a ftraight radial lever, which is eafily fhaped; thefe formations will act pretty well together, and when they are adopted, the outer ends of the teeth of the driven one muft be in its primitive circumference; but in the driver the whole tooth muft project beyond its primitive circle; fo that the two primitive circles, geometrically obtained, muft not meet at what is called the pitch-line, but be feparated by a fpace equal to the length of the driving tooth; but in practical works, particularly in horology, the teeth of both the driver and driven wheel or pinion are ufually formed nearly alike; partly by means of the exterior epicycloid, and partly by means of the interior one, or ftraight line; the exterior ends are formed ufually by being curved, and the interior parts are bounded by radial ftraight lines, either of which parts will drive the other, which office they do alternately; this fhape is not only found to be the moft practicable, but admits of a contact of the two primitive circles at a point of each tooth, called the *pitch-line*; the confequence of which formation is, that nearly an equal addition may be made to each curve for the rounded parts of the teeth of both the wheel and pinion; it is this formation that we mean when we fpeak of ordinary teeth, and to which our table is applicable, which is given under the article CLOCK-*making*.

Olaus Roemer, the celebrated aftronomer and mechanift of Denmark, according to Wolfius and Leibnitz, was the firft who pointed out the utility of the epicycloidal curve, when applied to delineate the fhape of a tooth; but De la Hire took up the fubject after him, and demonftrated, that if a tooth of either a wheel or pinion be formed by portions of an exterior epicycloid defcribed by a generating circle of any diameter whatever, the tooth of its fellow will be properly formed by portions of an interior epicycloid, defcribed by the fame generating circle, which curious circumftance allows of an infinite variety in the two correfponding curves that form the teeth of the wheel and pinion, if they were practicable. Nay De la Hire has fhewn, that if the teeth of any wheel be triangular, circular, or of any other regular figure, an uniformity of force and velocity may be mutually imparted, provided the teeth of the correfponding wheel or pinion have its teeth formed by a figure, compounded of the epicycloid and faid figure, which he has further fhewn the method of effecting in a variety of cafes, not however adapted for practice. But whether the mechanift may choofe to ufe his exterior and interior epicycloids jointly in the fame tooth, or feparately, in different wheels acting together, this practical rule ought never to be loft fight of, *viz.* the outer end of his interior, and alfo the inner end of his exterior epicycloid fhould univerfally commence in the primitive or geometrical circle of his wheel or pinion.

The reader is now prepared to be told, what otherwife might have appeared paradoxical, not only that the fame pinion, of eight leaves for inftance, will require the teeth of a wheel of thirty to be fomewhat differently rounded at the ends, from thofe of a wheel of fixty, or any other number, in order to have like action in both cafes, but that, however accurately the teeth of wheels are rounded, all numbers are not equally good to be ufed indifferently for wheels and correfponding pinions. This latter part of our fubject has not been much attended to in practice, but is curious, and may contribute to great utility, particularly in horology, where an equable tranfmiffion of velocity and force is defirable.

The whole of what we have hitherto faid refpecting the action of epicycloidal teeth, has been upon a fuppofition that the impelling force begins at the line which joins the centres of any pair of wheels, or of a wheel and pinion, and is exerted outwards always on one fide of this line until the teeth efcape one another, which mode is allowed to be the beft, when it can be effected; but there are many ratios, and thofe in common ufe between a wheel and its pinion, which will not admit of this kind of action, however good the fhape of the teeth. Indeed, Camus has fhewn, that no pinion lefs than one of eleven leaves, will entirely anfwer the purpofe of acting always on one fide of the line joining the centres, and that confequently the common pinions of fix are very ill calculated to effect an equable tranfmiffion of velocity and force, by reafon of their leaves acting alternately before and behind the line of the centres.

In *fig.* 5, fuppofe H K to be a portion of a wheel of 50 teeth, and kh a pinion of feven thin leaves or levers, each like cbh; Camus has proved, that this wheel will not impel its pinion in an uniform manner, by acting always behind the centres. His reafoning is to this effect; in order that the leaves of a pinion of feven, may be impelled only behind the line joining the centres, the tooth, P b H, of the wheel muft not quit the leaf ch, until the next following leaf, cI, has reached the point, P, in the line of the centres, in order that it may be impelled in its turn by the next tooth, K I, behind that line. The angle I c h, or quantity that one leaf of the pinion muft be moved before the following one comes to the line of the centres, is one feventh of 360°, or 51° 25′ 43″ almoft; confequently the angle C c h, or C cb, is 51° 25′ 43″. Then taking the radius of the pinion at feven parts, the fide cb of the fmall right angled triangle, when folved, will be 4.364

4.364 of fuch parts; alfo in the triangle b C c we have the two fides $c\,b$ as before, and c C equal 57, with the included angle $b\,c$ C, from which data, by a folution of the problem, we have the angle b C c equal $3°\ 35'\ 50''$ nearly. The angular quantity of the wheel H C I, which one tooth and one fpace occupy, or $\frac{1}{50}$ of $360°$, is $7°\ 12'$, from which, if we deduct the angle b C c, or $3°\ 35'\ 50''$, the remainder, $3°\ 36'\ 10''$, will be the angle H C b. Now, as the two epicycloidal portions of the tooth P b and H b are equal and fimilar, and alfo fimilarly placed with refpect to the full radius C b, and as the angle H C b has been found to be $3°\ 36'\ 10''$, the angle H C P, which ought to contain one tooth and fpace, will be $7°\ 12'\ 20''$; but we have feen that the angle H C I is only $7°\ 12'$, confequently the angle H C P will be greater than H C I by $20''$, which is impoffible, becaufe a part cannot be greater than the whole. It is, therefore, impoffible that a wheel of 50 fhould move in an uniform manner, a proportionate pinion of feven leaves impelling them only behind the line joining the centres. A wheel of fewer teeth than fifty will be ftill lefs proper, and one of a greater number will not leave fpace enough for a fufficient thicknefs of leaf in a pinion. Hence it appears, that when a pinion of feven leaves is ufed, it will be impelled by its wheel, partly before and partly behind the line joining the centres, as may be feen more fully in *fig.* 6, where the pinion is fuppofed to be impelled by the wheel from right to left.

In the fame manner it may be proved, that if a wheel of 57 were made to drive a pinion of eight, the whole arc for both the tooth and fpace would be $6°\ 18'\ 57''$, of which $5°\ 7'\ 40''$ would be occupied by the tooth of the wheel, and only $1°\ 11'\ 17''$ by the fpace, or by the tooth of the pinion, which quantity is not enough for the thicknefs of an acting tooth; therefore if the teeth of the wheel are made nearly equal to the fpaces, they will drive the pinion of eight both before and behind the line of the centres.

Alfo if a wheel of 64 were to drive a pinion of nine leaves in fuch a way, that the impulfe might be only behind the line of the centres, the arc at the pitch-line of the wheel for both tooth and fpace, will be $5°\ 37'\ 30''$, of which the tooth will occupy $3°\ 45'\ 42''$, and the fpace only $1°\ 51'\ 48''$, which will not leave room for a leaf fufficiently thick for the pinion.

Likewife where a wheel of 72 drives a pinion of ten leaves behind the line of the centres, the arc of the wheel's tooth is $2°\ 47'\ 16''$, and of the fpace between two teeth $2°\ 12'\ 44''$ only, therefore here the tooth and fpace cannot be equal.

In pinions of 11, 12, &c. the impulfe may take place entirely behind the line of the centres, and the extreme ends of the teeth might be taken away, as in the pinion of *fig.* 6, and in the two teeth of the wheel, which are fuppofed to have paffed the centre. Nay, in thofe cafes where the pinion is always driven by an impulfe made only behind the line of the centres, the addition to its tooth beyond the geometrical diameter, may, as we have faid, be nearly difpenfed with; that is, the acting and the geometrical diameters may be almoft the fame, provided the angular points be a little rounded to prevent their catching and fcraping the teeth of the wheel, though it is fafer to give a little addition for the curves.

Under our article CLOCK-*making*, we faid that the driving wheel or pinion ought to be fomewhat larger than according to its calculated proportion; but we did not give the reafon there, which is, that in thofe cafes where the teeth are actuated both before and behind the line of the centres, the impulfe of the tooth before the line of the centres takes place later than it otherwife would do, as well as occafions a fmaller fhock at the commencement of the impulfe. The defect attending fuch a conftruction is a little more velocity in the driver than in the driven wheel or pinion, but this is confidered as of lefs importance than the fhock otherwife occafioned in movements, with pinions of low numbers.

It is of the utmoft importance, that the mechanift fhould bear in mind another practical rule, which we have now to offer, as it arifes out of the preceding difcuffion of this fubject, which is, that, in all ordinary cafes of wheel-work, the portion of an interior epicycloid of any tooth, whether that portion be a curve or ftraight line, fhould always drive the portion of an exterior epicycloid of the tooth of its fellow, before the line joining their centres; but that, on the contrary, a portion of an exterior epicycloid muft always drive a portion of an interior epicycloid, whether the latter be a curve or ftraight line, after the line of the centres.

We are not, however, to infer from this rule, that it is a matter of indifference, whether a wheel drive its pinion, and a pinion its wheel, before or after the line joining their centres; for in the action that takes place before this line, there is much friction occafioned, by the fliding of the tooth of the driver, along that of the driven wheel or pinion, as well as an accumulation of dirt occafioned at the bottom of the tooth of the latter; whereas, when the action is after the line in queftion, the teeth roll on one another, and the dirt is carried out of the fpace between the teeth; this confideration is the greateft recommendation of that kind of action, where an exterior epicycloid impels an interior one only after the line of the centres, which mode we have feen, cannot take place with low pinions; from which view of the fubject the direct inference is, that pinions of high numbers ought to be adopted in every cafe that admits of fuch an adoption. We may alfo refer to the fame caufe the origin of the common bay-leaf fhape of a tooth, which impels both before and after the line of the centres, and acts at the pitch-line, at the moment of paffing this line.

The epicycloidal teeth, fuch as we have defcribed, are not however the only ones which have the requifite property of tranfmitting the force and velocity uniformly, though we have hitherto confined our obfervations to thefe fhapes, by reafon of their being moft generally ufed. Two teeth which are formed by the evolution of threads from their refpective geometrical circles, as feen in *fig.* 7., and which are fhaped by the interfection of portions of their refpective involutes, though lefs known and confequently lefs ufed, have, according to the late profeffor Robinfon and others, the fame requifite property as the foregoing ones, and may be ufed inftead of them in practice. The curve formed at any point, i, by a thread refting at the point H, of the wheel or point, h, of the pinion, is perpendicular to the thread, and the thread is a tangent to the circumference of the circle from which it is evolved; whenever therefore one tooth drives the other, the point, i, of action lies in the line H h, which is a common tangent to both circles, and the force is conftantly exerted in the direction of the common tangent, in every pofition of the acting teeth; the nature of the action confequently will be precifely the fame as though the points H and h were in contact, and impelled each other at the point of contact, hence the angular velocity of K H, will be to the angular velocity of $k\,h$, as the radius, $c\,h$, is to the radius C H; that is, the motion and force communicated will be uniform.

It is evident from an infpection of the figure, that when teeth compofed of interfecting involutes are ufed in a pair of of wheels, or in a wheel and pinion, the geometrical radii must have the whole length of their respective teeth added to them to constitute their acting radii; and also, that the two proportionate circles which come in contact and designate the place of the pitch-line in ordinary epicycloidal wheel work, must be removed from each other to a distance equal at least to the length of the longer tooth. This length will depend upon the geometrical radius of the wheel or pinion, and coarseness of the tooth conjointly. In large wheels the tooth will be long, and in small ones the contrary, where the coarseness is the same, the breadth of the tooth being in every instance the abscis, and its length the ordinate of the involute or curve that forms one side of the tooth. The full length of any tooth of a given coarseness, in a wheel of a given diameter, may consequently be ascertained by a fluxional process, which we intentionally avoid as being too intricate for ordinary purposes.

This formation of a tooth, where the involute is derived from the wheel or pinion's own circumference, is recommended by professor Robison, on account of its admitting the simultaneous action of many teeth, thereby participating the force among them; but as he does not profess to say that they act without friction, we conceive that horology would not be benefited by their adoption, even if the formation were practical. Mr. Brewster, in his new edition of Ferguson's Lectures, vol. ii. page 223, has properly observed, that the principle of the professor's teeth is not new. De la Hire having long ago considered the involute of a circle as the last of the exterior epicycloids, which it may be proved to be, if we consider the generating straight line as a curve with an infinite radius; and the involute may be described most conveniently by a ruler or other straight edge, bearing a tracing point moved round the circular base, while they are kept in contact. Accordingly, our rule for the situation of the geometrical or primitive circles holds good. The teeth which project beyond these circles are formed by portions of exterior epicycloids; but our rule for the action before and after the line of the centres, cannot, in this case, apply, because here the interior epicycloid is not concerned, and the formation of the exterior one has no reference to the diameter of its fellow. (Vide the articles EVOLUTE and INVOLUTE.)

After having said so much on the requisite shape of a tooth in a wheel or pinion, to transmit the motion and force equably through a movement; we might here add the necessary directions for calculating the suitable numbers for constituting movements of various kinds; but these have been anticipated under the article CLOCK-*making*, to which the reader is desired to refer, and in which he will see that we have divided the whole movement of the going part into three portions; any one of which may be altered at pleasure, without affecting the other two. Upon the plan there laid down, we have calculated three separate tables of the different portions, which we subjoin, with a view of giving a great variety of trains, to be had by mere inspection, and of thus saving the clock-makers the trouble of going through tedious calculations, according to the prevailing custom of taking into one calculation the whole movement at once, and of breaking it into portions by a substitution of ratios equal in value to the different factors of an assumed product, which process makes the determination intricate.

Explanation of Table I.—Table I contains numbers suitable for the great wheel, and the pinion on the arbor of the centre wheel, together denominated "the first portion of a clock-movement," which is that on which the duration of motion at one winding up depends: the numbers on the uppermost horizontal column, from 6 to 16 inclusively, represent so many pinions; the numbers in the first vertical column, from 3 to 16 inclusively, are the respective hours in which the barrel or fusee turns once, as the case may be; and the larger numbers beginning with 18, and ending with 256, in the intersections of the horizontal and vertical columns are the great wheels. By way of exemplification, suppose we want a fusee to revolve in twelve hours, with a pinion of 8 on the arbor of the centre wheel, the intersection of 12 hours at the left-hand side, and eight at the top, gives 96 for the number of teeth in the great wheel, to produce the desired effect; or if the pinion had been required for a wheel of 96, to revolve in 12 hours, over 96, in the column of 12 hours, stands the pinion 8. In the same manner for 4 hours, and a wheel of 48, the pinion will be 12, and *vice versâ*.

Explanation of Table II. Table II. contains wheels and pinions suitable for the second portion of a clock-movement or first portion of the train, being that which effects a multiplication of 60, and regulates the velocity of the seconds' hand, by making its arbor revolve in one minute. This might be done by one large wheel of 300, and a small pinion of 5, but such a construction would require a large frame; a composition of two wheels and two pinions is therefore substituted to produce the same effect more conveniently, the first wheel being placed on the centre or hour arbor that carries the minutes' hand, and the last pinion on the arbor of the seconds' hand that revolves in a minute. The uppermost horizontal column contains the pinions from 6 to 16 inclusive, like Table I., and the left-hand vertical column contains couplets of factors, which, multiplied together, produce 60 always as a product. Any pair of factors, which are coupled together by a $\}$, may be taken at pleasure, and the wheels in the spaces made by the intersections of the vertical and horizontal columns, under the pinions made choice of, and opposite the factors selected, will be proper for the second portion of the movement. For instance, when pinions of 8 are used with the factors $\left.\begin{matrix}7\frac{1}{2}\\8\end{matrix}\right\}$, the wheels, found in the space formed by the intersection of the vertical column under 8 and horizontal column in which $\left.\begin{matrix}7\frac{1}{2}\\8\end{matrix}\right\}$ stand, are 64 and 60; but if the pinions were to be assumed, one 10 and the other 8, then the wheels would be either 80 and 60, or otherwise 75 and 64, accordingly as the pinion 10 is made a part of the ratio to represent the factor 8, or the factor $7\frac{1}{2}$, which it may be taken to do indifferently; hence the notation may be $\frac{10}{80} \times \frac{8}{60}$, or $\frac{8}{80} \times \frac{10}{60}$, or $\frac{10}{75} \times \frac{8}{64}$, or $\frac{8}{75} \times \frac{10}{64}$, the result in point of accuracy is the same, but in the construction, the wheels of largest diameter and weight are required to be taken first in the movement, because the diameters diminish as the train ascends, by reason of the diminution of the transmitted force, which otherwise would not overcome the inertia of the wheels, which it is required to do at each vibration of the pendulum: any two pair of wheels and pinions properly taken out of the corresponding columns when reduced to a simple ratio by the usual method of multiplying the numerators together for one numerator, and the denominators for one denomination, will be found equal to $\frac{1}{60}$; thus $\frac{10}{80} \times \frac{8}{60} = \frac{80}{4800} = \frac{1}{60}$, and $\frac{10}{75} \times \frac{8}{64} = \frac{80}{4800} = \frac{1}{60}$, as before; therefore, if the first wheel revolve in an hour, the last pinion will, in this and in every other instance, revolve in a minute. The diminution of the diameter of the third wheel of the movement, which is the second wheel of the train, may be effected in two ways, either by taking the seconds' pinion smaller than the first from a column at the bottom of the table, where the factors are nearly of equal value, or by taking the pinions alike, and the wheels from one of the higher horizontal columns where the factors differ considerably in value; thus $\frac{7}{60} \times \frac{6}{42}$ from column $\left.\begin{matrix}7\\8\frac{4}{7}\end{matrix}\right\}$ and $\frac{7}{70} \times \frac{7}{42}$ from column $\left.\begin{matrix}6\\10\end{matrix}\right\}$ are each equal to $\frac{1}{60}$, but in the first portion of the movement the ratio of the size of the two wheels is 60 : 42, and in the other 70 : 42, from which mode of comparison of the columns it will be seen that a decrease in the diameters of almost any given ratio may be adopted from this table, so comprehensive is its extent, as it relates both to the variety of 11 pinions, and to the choice of 10 pair of factors, which begin with the ratio 4 : 15, or 1 : 4, and end with $7\frac{1}{2}$: 8. The

The principal care to be taken is, that every wheel be taken under its own pinion and opposite its own factor; for another instance, in the horizontal column of factor $\left.\begin{matrix}6\frac{2}{3}\\9\end{matrix}\right\}$, the pinions of 9 will do for wheels 81 and 60; or otherwise, wheel 90 may be taken with pinion 10, and wheel 60 with pinion 9; that is, any wheel may be taken opposite its own factor, provided the pinion in the same column over it be used as its fellow; so that examples may be given to a very great extent, which will afford abundant means of ascertaining by experiment the best possible numbers for this part of the movement, without the trouble of calculation.

Explanation of Table III. Table III. contains the third portion of a clock-movement, or second portion of the train, which is that on which the number of vibrations per second depends. When a vibration is performed in an exact second, one wheel only is necessary for this purpose, with 30 teeth, because one tooth completely escapes the pallets at every second vibration, which wheel must be placed in this case on the arbor of the seconds' hand, and is usually denominated the swing wheel; also a wheel of 60, similarly placed, will be proper for half seconds, 75 for $2\frac{1}{2}$ vibrations per second, and 90 for 3 per second; but these last numbers are found too high for portable clocks, time-pieces, &c. therefore a wheel and pinion are introduced in addition to the escapement-wheel, in order to diminish its diameter into a convenient size for a portable construction, as well as to render it light, so as to have but little inertia to be overcome by the diminished force, which acts at this part of the movement. In ordinary pieces the two wheels are, one a contrate-wheel, and the other called the crown-wheel, with the pinion on its arbor, but the wheels may all have the ordinary form of the wheels of a clock that swings seconds, it being not the shape, but the numbers of the teeth of the wheels and pinions that determine the frequency of the vibrations. The uppermost horizontal column in this table, like that in the two preceding tables, contains all the variety of pinions from 6 to 15 inclusively; the pinion of 16 being omitted, however, to make room for two additional vertical columns at the right hand of the table, the first for the number of vibrations per second made by the pendulum, and the other for the length of the corresponding pendulum in inches and decimal parts, measured from the centre of suspension to the centre of oscillation, which two data once fixed upon determine the horizontal column out of which the wheels must be taken with a given pinion; the left-hand vertical column is that in which one of the two wheels is found, and the number standing on the same horizontal line, under the given pinion, is the other; for as the product of the two wheels, divided by the pinion under which one of them stands, is always equal to 60 in the highest large column, or column of 2 vibrations per second, it is of no importance to the accuracy which of the two wheels is made the pallet-wheel; the determination of this point being a matter of practical convenience; in the same manner in the second large horizontal column, the quotient arising from the product of any two wheels standing in the same line taken horizontally, one in the first vertical column, and the other under the chosen pinion, divided by the pinion, is always 75; in the third parallel column the quotient so obtained is 90; in the fourth 105, and so on; hence any of the combinations adopted will be equal in value respectively to those large simple numbers used as pallet-wheels without such combination, which, it has been said, are objectionable in practice.

Let our first example be to ascertain the requisites contained in the table for a half-seconds' pendulum, where a pinion of 8 is used?

In the first place, 12 with 40 may be taken as the required numbers for the two wheels; in the second, 15 with 32; in the third, 20 with 24; and, lastly, 30 with 16; any one of which wheels may be the pallet-wheel, as the nature of the escapement may require; if the crown-wheel escapement is used, which requires an *odd* number of teeth for its action to take place at opposite sides of the wheel, 15 must necessarily be the pallet-wheel, and 32 the other, with the given pinion of 8: but whichsoever of these couplets of wheels is adopted, the effective length of the pendulum must, according to the last vertical column, be 9.80 inches.

Again, for a pendulum that is required to vibrate 3 times per second with a pinion of 12: we have, in the first place, 15 with 72; secondly, 18 with 60; thirdly, 30 with 36; and, lastly, 45 with 24; so that either 15 or 45 may be in this instance the crown-wheel, and for a different escapement any of the eight numbers mentioned; and the choice is equally extensive with any other pinion that may be chosen from 6 to 15: the pendulum in this case is only 4.35 inches.

In this way, by means of the table before us, the third portion of a clock-movement may be varied almost at pleasure without affecting the other two portions, and a pendulum of any of the calculated lengths may be applied to works previously constructed; which circumstance will enable the workman to metamorphose a portable clock into a large one, and the contrary, without difficulty, or without even a knowledge of the operations of arithmetic.

We might have extended this table to take in different intermediate lengths of the pendulum and corresponding number of vibrations per second, but our object is to banish incommensurate vibrations from clock-movements, and to introduce those only which constitute some convenient subdivision of the second, to answer the nicer purposes of philosophy without extra labour and expence. The three or four last horizontal columns indeed, it may be said, will not be of much service in clock-movements, by reason of the shortness of the pendulums; but they will be found particularly useful in watch-work, as will also the other tables, which are so comprehensive as to apply with equal propriety to clock and watch-movements.

Clock-*tools*. While clock-making was in its infancy, and the different parts of the machine continued to be made by the same workman, each clock-maker was obliged to design and manufacture his own tools agreeably to his own inclination; but as soon as the art branched out into different occupations, tool-making became also a business of itself, and is now quite distinct from clock-making, nay, has itself ramified into various branches. In the present state of this manufactory by far the greatest number of clock-tools are made in Lancashire, and become an article of commerce among the ironmongers all over his majesty's dominions. In London there are a few houses that deal chiefly in clock-tools, engines, and rough materials ready prepared, as to size and shape, for the workmen; one of the principal of these is Fenn's in Newgate Street, No. 105, where tools of all kinds may be had at moderate prices. It is much to be regretted that a Swiss tool and engine-maker, called Petitpierre, who lately worked in an attic of No. 161 Fleet Street, and who made tools and engines in a very superior manner, was some months ago obliged to quit the kingdom for want of regular employ, though his prices were by no means exorbitant.

It

It will not be expected of us, to prefent the reader with all the variety of tools that individuals have refpectively contrived, but to lay before him fuch a collection as cuftom has fanctioned in the trade; which we propofe to do in three plates, devoted entirely to this purpofe; neither will it be expected, that we fhould particularize all the different ufes to which any individual tool may be applied, much lefs to point out the pofitions in which they ought to be held in the act of working, which would require almoft an unlimited variety of plates; it feems to be fufficient for our general purpofe, if we give a lift of the different tools at prefent in common ufe, with references to the plates, where the reader will comprehend the nature and ufe of each tool by a furvey of its figure, better than from any verbal defcription without the figures. We fhall, therefore, confine the remaining portion of this article to a fimple explanation of the plates.

Plate XIX. *of Horology.*

Fig. 1. A motion-arbor, or arbor for turning wheels on, with a faftening nut.
2. Motion-arbor, that fcrews up to the fhoulder, with a fmall nut to faften.
3. A plain arbor for collets, or tubes, to hold by friction.
4. A flit arbor for holding and turning fmall pieces of metal.
5. A pair of cutting bullet-compaffes for fitting any central hole, in defcribing or cutting circles.
6. A cutting-leg for ditto.
7. A marking-leg for ditto.
8. A ftake, or fmall anvil, for hammering, &c. on.
9. Common flat, fhort-nofed pliers for holding any piece of metal.
10. A pair of callipers, with a ftraight edge, adjuftable by a thumb-fcrew, of ufe for trying if a wheel is placed at right angles to its arbor, or what is called in the flat, and alfo if it is perfectly concentric, or in the round.
11. Common callipers for meafuring diameters.
12. A frame-guage, infide and out.
13. A pinion-guage, with fpring and fcrew adjuftment.
14. Beam-compaffes for cutting out circular pieces of metal from a folid plate, defcribing large circles, dividing rectilinear and curvilinear lines, &c.
15. A fquare or rectangular piece of brafs.
16. A clamp for holding pieces of metal to be filed or riveted.
17. A drill-arbor and drill in a focket for various drills, to be ufed with a bow and gut.
18. A drill detached to fit the faid arbor.
19. A drill of larger fize.
20. A tool or graver for cutting grooves, which may be of various fhapes and fizes.

Plate XX. *of Horology.*

Fig. 1. A faw for metal, with a wooden handle.
2. Cutting pliers for fhortening pins or for cutting wire.
3. A bench-vice, or vice to be clamped to a bench.
4. A hand vice for holding a fmall piece faft.
5. Clamping pliers for holding pins, &c. faft in filing.
6. Pendulum-pliers or long-nofed pliers.
7. Pivot-drill with a friction-ferril.
8. Drill-arbor in a drill-frame, to be held in a bench-vice.
9. A drill to fit the focket of the arbor, when it has a fquare tapering hole.
10. Ditto of larger bore.
11. Screw-head tool, including the arbor and frame with a reft, to be put into a bench-vice.
12. A holding piece of ditto, detached from the end of the arbor, and tapped with a female thread, to hold the fcrew to be dreffed.
13. Ditto with a different thread.
14. A detached ferril for a drill or arbor.
15. Ditto in two halves, with adjufting-fcrews to fit any arbor or drill.
16. A fcrew plate with different holes tapped.
17. A tap to be held in a hand-vice, for making a female thread in any hole. *N. B.* When long fcrews are required to be made, a die, fuch as the mathematical inftrument-makers ufe, is better than a fcrew-plate, for preferving the fcrew from bending; there muft be as many taps as the plate has different holes tapped.
18. A fcrew-driver, of which there are various dimenfions.

Plate XXI. *of Horology.*

Fig. 1. A brace for receiving various bits.
2. A chamfering or counter-finking tool to fit the brace, for which a large drill may be fubftituted.
3. A pentangular or five-fided broach to fit ditto.
4. A round broach to fit ditto.
5. A fquare broach to fit ditto.
6. A deepening tool, for adjufting the engagement of wheels with wheels or pinions, not as yet much ufed in England.
7. Turning-frame, or clock-lathe, of which there are various fizes, and conftructions; fome going by a bow like the prefent one, fome by a hand-wheel, and fome by the foot with a large wheel and crank actuated by a lever which is trodden upon. See Lathe.
8. A graver for cutting the metal in a turning-fame.
9. A large ditto.
10. An adjufting-tool for fufees, with fliding weights, to fuit any given maintaining power of a clock or watch.
11. A tool for turning pivots in, when inferted into the end-hole of the turning-frame.
12. A triangular tapering-file.
13. A file for flitting or cutting the teeth of pinions.
14. An equalling file, or file for the fpaces between the teeth of a wheel, when cut in an engine.
15. A common hand-file with a fafe edge for ordinary work.
16. A rounding-off file, for the ends of the teeth in wheels and pinions.
17. A file for croffing-out, or forming the croffes and rim of a wheel.

Befides the above there are various other files differing in fize, fhape, and coarfenefs, according to the work they are defigned to perform.

Clock-*work.* The word *Clock-work*, in its original fignification, imported thofe wheels and pinions, latches, catches, fprings, fly, hammer, &c. which conftitute the ftriking, or what was formerly called the clock, part of the works of a large horological machine; but fince clocks became common and portable, the term has been applied in a more general fenfe to the mechanifm of the going part, as well as of the ftriking part, and even fometimes to the works of thofe machines, which refemble the works of a clock in their appearance and action. Under this head, therefore, we mean to defcribe fuch detached pieces of clock-work as are not to be generally met with, but which feem, either from their utility or curiofity, to merit a public notice.

1. *Striking Part, with one Wheel and one Pinion.—Fig.* 1, of *Plate* XXV. of *Horology*, is a front view of the ſtriking part of a clock, purchaſed in the year 1806, at the ſale of a gentleman in Suſſex, who is now deceaſed, but who indulged his fondneſs for mechanical contrivances, at an almoſt incredible expence; this ſtriking work is ſo ſimple, that it has only one wheel and one pinion, and no other fly but the hammer, itſelf, and is, notwithſtanding, capable of repeating the laſt hour at any time, with the addition of a ſtring attached to the lifting piece; after our minute deſcription of the ſtriking mechaniſm of an eight-days clock, with the ſnail and rack, it will not be neceſſary for us to repeat what we have already ſaid on their action, but merely to confine ourſelves to the movement, bell, and hammer. The frame of this clock is in the ſhape of a croſs, confined by the pillars A, B, C, and another below, not ſhown; the great wheel of the ſtriking part has 300 teeth, with a barrel and ratchet as uſual on its arbor; it is actuated by a weight ſuſpended by the chain D, and drives a pinion of ſix leaves, when at liberty to move; F is a rack placed on a long lever, the tail of which, as uſual, reſts on a ſnail, on the 12-hour wheel; and G is a lifting piece to raiſe the click or hawk's-bill H, which it does by means of a pin ſliding underneath the piece H, whenever the pin in the one hour wheel moves its tail, as uſual: on the protruding end of the pinion's arbor, a gathering pallet is fixed in the common way, the long tail of which reſts on the pin at the right-hand end of the rack, when the rack is gathered up to the laſt tooth; and the click, H, is heavy enough to fall by its own weight, after ſliding over the inclined part of any tooth; all which actions are ſimilar to thoſe we have before deſcribed in *Plate* XII. The bell is mounted on the uppermoſt pillar, as ſhown in the figure, and a lever, I, is faſt to the middle of the pinion's arbor within the frame; this lever has what may be called a leg, ſuſpended by a pin at its remote end, forming what we will call the knee-joint of the leg, the foot of which leg forms the hammer: now, it is eaſy to perceive, that when the pinion begins to revolve ſuddenly, the foot of the leg flies out by its centrifugal force, and the toe moves in the curve *a*, where it meets with the edge of the bell, againſt which therefore it ſtrikes and rebounds, by permiſſion of the knee-joint, to *b*, we will ſuppoſe, the place where it would have been found if the motion had been ſo ſlow as to have no centrifugal force: but this point is in the interior part of the bell, the foot therefore proceeds within the bell, and the revolution is completed ſilently, but at the next, and at every ſubſequent revolution, this ſtroke and conſequent rebounding are repeated, till the rack is gathered up, which regulates the number of ſtrokes. The ball, K, is only a counterpoiſe fixed on the tail of the lever I, and aſſiſts with it to form a kind of fly, to regulate the velocity with which the ſtrokes are ſucceſſively made. This mechaniſm is very ſimple, and appears to have been made many years, from the dirty ſtate in which we ſaw it; but has not, that we know of, been before deſcribed.

In the year 1803, the Society of Arts, in the Adelphi, London, voted to Mr. Edward Maſſey, of Hanley in Staffordſhire, a premium of twenty guineas, for a new ſtriking part of a clock; and in the ſame year, another premium of thirty guineas, to Mr. John Prior, of Neſsfield in Yorkſhire, for another contrivance to anſwer the ſame purpoſe: the drawings and accounts of both theſe inventions, were publiſhed in the tranſactions of the ſaid ſociety, for the year above ſpecified; but the deſcriptions, as there given, are ſo imperfect, that we have found it neceſſary to have new drawings taken from the models themſelves, which are preſerved in the repoſitory of the ſociety, from ſuch points of view that the action of the different parts may be rendered as intelligible as poſſible. We ſhall deſcribe Mr. Maſſey's contrivance firſt, as being ſomewhat analogous to the one we have juſt deſcribed, inaſmuch as that it has one wheel and one pinion only, inſtead of a train of wheels and pinions, as is uſual.

2. *Maſſey's ſtriking Part. Fig.* 1, of *Plate* XXVI. of *Horology*, is a perſpective view of Mr. Maſſey's model, with the front plate of the frame removed, or ſuppoſed to be tranſparent, to ſhow the mechaniſm included. A is the great wheel with 78 teeth, like the ordinary count-wheel, impelling the pinion *a* of eight leaves; on the arbor of pinion *a*, but at the oppoſite end, is a circular plate, B, with eight pins placed in a concentric circle, at equal diſtances, ſo that one pin correſponds to one tooth of the pinion; theſe pins being near the circumference of the circular plate act with the pallets *b*, *b*, and form a kind of eſcapement; the pallets are connected with a pendulum of about 9 inches long, which therefore vibrates pretty nearly half-ſeconds, between the eſcape of each ſucceſſive pin reſpectively. It is not neceſſary to ſhow the pendulum which may be hung on a cock, or on the pivot of the pallet's arbor, which is more ſimple for this purpoſe, and not objectionable, as it would be in the going part. The lever, *d*, is a locking detent, with a claw for locking the pins of the plate B, when it falls in the way of any one of them; on the arbor of the detent, *d*, is another detent with a triangular claw, *e*, which falls in the way of the pins of the great wheel, placed at unequal diſtances, like the notches in the locking-plate of a count-wheel; on which account the great wheel may be conſidered as a count-wheel alſo; to the ſame arbor of *d* and *e*, is alſo attached a third concealed lever, which reaches to the one hour wheel, and is moved by its pin once in each hour, in the ordinary way. On the poſterior face of the locking-plate, B, are eight pins in a ſmall concentric circle, dotted in the figure, which lift the hammer tail as uſual, to which a counteracting ſpring is applied, to give a ſmartneſs to the ſtroke of the hammer, as it ſtrikes the ſide of the horizontal bell, mounted over the frame, as ſhown in the figure. The action is thus; when the detent, *d*, is raiſed, by the pin of the one hour wheel of the dial-work not ſeen, the weight ſuſpended by the cord C, draws the barrel on the arbor of the great wheel round, and with it its ratchet, which takes the click of the great wheel, and therefore carries it alſo, the detent *e* being lifted at the ſame time with the detent *d*; the wheel now impels the pinion and plate B, which is not only the locking but ſtriking plate alſo; the pins begin to lift the hammer in ſucceſſion, and the ſtriking goes on; in the mean time the detent, *d*, falls within the circle of pins, as in the figure, in conſequence of the lifting pin of the one hour-wheel letting go the concealed lever, but ſo as not to impede the paſſage of the pins of the locking plate; preſently the neareſt following pin of the great wheel ſliding on the inclined face of the detent *e*, raiſes it far enough to move the claw of the detent, *d*, into the way of the pins of the locking plate, and then all motion is arreſted, till the dial-work raiſes the detents again at the end of another hour, when the ſame proceſs is repeated, the vibrations of the pendulum regulating at all times the velocity with which the lifting pins of the hammer-tail ſhall move ſucceſſively during the period of ſtriking.

3. *Prior's ſtriking Part. Figs.* 2 and 3 of the ſame plate, exhibit in perſpective the mechaniſm of Mr. Prior, which we have already mentioned. A is the great wheel of 78 teeth, which impel the double endleſs ſcrew, B, cut on the arbor of the fly C C; like *fig.* 1, this figure has the front plate of the frame ſuppoſed to be tranſparent, to expoſe the different levers, &c. to view in their reſpective ſituations of action; on the arbor of the great wheel is the barrel, as in

fig. 1; in a concentric circle, near the edge of the large wheel, are ſeven pins, at unequal diſtances, which catch the claw of a detent *a*, placed faſt to the arbor *b*, which arbor *b* has a play or motion in the direction of its length, that will allow its pivots to go more or leſs into the plates of the frame reſpectively, as circumſtances may require, and a ſpring preſſing on the end of the pivot, which comes to the front plate, puſhes it back towards the wheel, whenever this preſſure is not taken off; the ſpring alluded to being on the front plate, of courſe cannot be ſeen in the figure; alſo a ſmall circular plate of metal, carried by the arbor of *b*, juſt fits into a circular groove turned out on a contiguous and parallel arbor *d*, in ſuch a way that the arbors can revolve independently; but when one moves lengthwiſe acroſs the frame, the other muſt neceſſarily move with it, for which purpoſe the ſecond arbor, *d*, has alſo liberty or play lengthwiſe like the arbor *b*; to this arbor *d*, is fixed a ſecond detent *e*, with a claw turning inwards; *f* is a third arbor, parallel to the other two, but below them in the frame, carrying about its middle the long tail *i* of the hammer K, and at the end next the front plate a ſmaller tail, to be preſſed by the ſpring, *g*, in the act of ſtriking; on the plane of the great wheel next the eye, are 13 pins, which ſucceſſively lift the hammer by the tail *i*, while the great wheel revolves; on the face of the great wheel, beyond the inferior circle of pins, and within the ſuperior one, is a ſpiral groove, with ſix complete turns, into which the outer end of the detent *e* ſlides as the great wheel revolves; ſo that if the groove were equally deep and ſmooth throughout, the bent end of this detent would be carried gradually from the innermoſt to the outermoſt helix without ſtopping; but the fact is, that at certain intervals in the ſix-fold ſpiral, there are deep notches at the bottom of the groove into which the detent inſerts its claw by the preſſure of the ſpring, which we have ſaid is not to be ſeen; and whenever one of theſe depreſſions of the detent *e* takes place, not only its arbor *d*, but alſo the arbor *b* are carried towards the great wheel by their motion lengthwiſe, ſo that the claw of the detent *a* comes in the way of the ſuperior pins of the great wheel; the excavated notches in the bottom of the ſix-fold groove are ſo arranged, in point of relative diſtances, that the 12 are placed at ſuch intervals of the ſpiral as gradually increaſe, like the intervals between the notches of the locking plate on a count-wheel. The action takes place in this manner; the arbor *b* has a lever connected with the pin of the one-hour wheel of the dial-work, by which it is lifted every hour; this lever is not ſeen by reaſon of its being at the other ſide of the plate B A; at the ſame time the detent *a* is raiſed, and ſets the pins at liberty, the weight ſuſpended by the cord *h* now turns the wheel and fly; the detent *e* in the mean time advances in the ſpiral groove, and the 13 pins in the inferior circle raiſe the hammer, which as often ſtrikes the bell mounted horizontally over the frame; when the detent is at the beginning of the firſt ſpiral of the half dozen, one ſtroke only is made, until the excavation at the bottom of the groove allows the claw to drop into it, which drop preſents the claw of the detent *a* to the neareſt pin, and ſtops the ſtriking; after another hour the detent *a* is again raiſed, and the wheel proceeds to move, ſo that when the detent drops again it does not fall in the way of the pins, but continues at a little diſtance from their heads, ſo long as the bent end of detent *e* does not fall into the next excavation of the groove; when this happens, however, it then falls in the way of the ſaid pins, but in the mean time two ſtrokes have been given, and in the ſame manner the hours 3, 4, 5, &c. will be ſtruck till the hour of 12 arrives; at this hour the wheel is unlocked as before, and as ſoon as 10 out of the 12 ſtrokes of the hammer are made, the end of the detent *e* comes at an inclined plane *l*, which it aſcends till it is above the plane of the wheel, and at that inſtant falls by its own gravity to the beginning of the ſpiral neareſt the centre, in which it then begins to move, while the remaining two ſtrokes of the 12 are making, after which it falls into the excavated notch where we firſt found it, and the whole proceſs has now been gone through. It may have occurred to the reader, that during the fall of the detent *e*, by its own weight, from the outermoſt to the innermoſt groove of the ſix-fold ſpiral, the ſpring acting on the neareſt pivot of the arbor *b*, would carry it againſt the plane of the wheel, and make it catch one of the ſuperior grooves before it arrived at the bottom one; this would actually have been the caſe, if there had been no precaution taken to prevent ſuch accident; but the contrivance ſhown in *fig.* 3, is introduced as a preventive, which acts thus; the little lever under the ſlender ſpring turns on a ſtud ſcrewed into the interior face of the pillar plate, or that which we have repreſented as the pillar plate; this lever reſts on the ſhoulder of the projecting pivot, which is brought forwards into the frame, when the end of *e* aſcends the inclined plane we have mentioned; at this inſtant the ſpring forces the lever down between the ſhoulder of the pivot and the pivot hole, and prevents the return of the pivot, when the lever *e* is falling; and for a ſhort time after; but while the two laſt ſtrokes of 12 are making, a pin in the back face of the great wheel ſeizes the tail of the lever, and raiſes it from the ſhoulder and pivot hole again, until the pivot has returned to the ſituation it occupies when the wheel is locked. This mechaniſm, we think, is ingeniouſly contrived, and is very ſimple; inaſmuch as only one wheel is uſed as great wheel, count-wheel, locking wheel, and ſtriking-wheel, without even ſo much as a ſingle pinion; there are 78 teeth in the wheel, and 13 pins for the hammer-tail, $\frac{78}{13} = 6$, therefore, are the teeth that paſs at each ſtroke; but the ſcrew is double, and takes two teeth at once, hence the fly makes juſt three revolutions at each ſtroke of the hammer; and a ſmall weight is ſufficient, not only to maintain the motion of the wheel, but alſo to overcome all the obſtacles it meets with, which recommendations bid fair for bringing this ſtriking mechaniſm into uſe in thoſe clocks, where the repetition is not deſired.

4. *Strike or ſilent.* When we deſcribed an eight-days clock with the mechaniſm of repetition, we had occaſion to explain one of the methods of cauſing the clock to ſtrike or be ſilent by the mere ſliding of a pin to the right or left; but there is alſo another method of doing the ſame thing, which we propoſe to deſcribe here as a detached piece of mechaniſm. *Fig.* 2, of *Plate* XXV. ſhows all the parts that are neceſſary for explaining the mechaniſm we have alluded to. A is a cock on the front plate of the frame, into which a ſmall circular plate *b* is pivoted, on the arbor *a*, of which is inſerted the ſquare hole of a hand ſeen on the dial, pointing to one of the words *ſtrike*, or *ſilent*, engraved, or otherwiſe marked, in a ſmall circle near one corner of the dial uſually, but ſometimes at the top, accordingly as the other works require; B is a lever ſlit open at the top, and moveable on a ſtud, at the angular point where the tail *c* is inſerted; and *d* is the portion of an ordinary rack with two pins in it, one at the end of the circular part as uſual, and the other at *d*, where the tail, *c*, of the ſlit lever, B, is ſeen reſting; laſtly, *e* is the pin in the front plate againſt which the rack falls as uſual, when the ſnail is off, or when the clock ſtrikes 12. The uſe of this mechaniſm may be explained in a few words thus; when the hand on the arbor *a* is turned to *ſilent*, as in the preſent poſition, the tail *c*, of B, falls in the way of pin *d*, and

d, and prevents the ſpring of the rack-tail from throwing the rack back; in conſequence of which obſtacle, the tail of the gathering pallet continues on the other pin, at the end of the curved part of the rack, and the ſtriking mechaniſm continues to be locked: but when the hand we have ſpoken of is turned to the word *ſtrike* on the dial, the tail, *c*, of the ſlit lever is raiſed above the pin, *d*, the rack falls without impediment, and the ſtriking takes place as though the mechaniſm before us had not been in the clock.

5. *Endleſs Cord of Huygens.* The reader has already read a partial deſcription of an endleſs cord, for keeping a clock in motion during the act of being wound up, when he peruſed our account of a thirty-hours clock; to do juſtice to Huygens, the original inventor, and to make the contrivance more clearly underſtood, we beg leave to refer the reader to *fig.* 3, of *Plate* XXV. where the contrivance in queſtion is diſtinctly exhibited in a way that we preſume will make it clearly underſtood. A is a metallic pulley, with pins inſerted into the bottom of its groove, and placed faſt to the centre-wheel without a ratchet; B is a ſimilar pulley, with pins and a ratchet wheel faſtened to it; the pulley and wheel, together with the click C, and its ſpring D, are all placed faſt in a detached ſtate on the frame, or caſe of the clock, as may be moſt convenient; E is a pulley, round which the endleſs cord goes, after this cord has embraced both the ſuperior pulleys, and to this pulley is attached the maintaining power, F, one half of the weight of which reſts on the pulley, A, and the other half on the pulley, B, ſo that this power is double the weight of an ordinary power, ſuſpended by a ſingle cord round a barrel; the cord, G, which goes round all the pullies, as repreſented in the figure, is made ſhort in the plate, for the ſake of being made an endleſs one, and is kept ſtretched by the ſmall weight H, and correſponding pulley. Suppoſe it to be neceſſary now to draw up the power, F, at any time; the hand takes hold of the cord at G, and pulls it down, the pulley, B, turns round in conſequence of its pins being caught by the cord; and the click ſlides over the inclined teeth, and holds the ratchet in whatever ſituation it is left when the hand lets go the cord; the pulling down of the cord, G, pulls up the part, I, of the cord, and with it the power, F, while the pulley, F, rolls along the part, K, of the ſame as it aſcends, which part, K, does not alter its ſituation, except by the ſlow revolution of the pulley, A, *i. e.* by the going of the clock; in the mean time the ſmall weight, H, falls towards G, and deſcends at the ſame time that F aſcends, till this power, F, approaches the two pulleys A and B, when the winding concludes by means of a ſtop applied over the pulley, E, to prevent the further aſcent of the power, F. From this brief account of the mechaniſm before us it is evident, that one half of the power, F, continues to actuate the pulley, A, during its aſcent, as well as during its deſcent, and that the quantity of fall compared with half the circumference of the pulley, A, will determine the continuance of going after each winding up.

6. *Forcing Spring.* We have ſeen the application of an auxiliary ſpring, attached to the fuſee of a chronometer, and to the barrel of an aſtronomical clock, conſtituting the former a going fuſee, and the latter a perpetual ratchet, both of which anſwer the ſame purpoſe as the endleſs cord we have juſt deſcribed; but there are other applications of a ſpring to produce the ſame effect, that have not yet been deſcribed. *Fig.* 4, of *Plate* XXV. repreſents a ſpring of this kind acting in the teeth of the ſecond wheel of the train, as we have ſeen it in ſome old Engliſh clocks. A and B are portions of the two plates of a clock frame; C, the ſecond wheel of the train; D, the arbor of a ſliding pallet; H, moveable in the ſmall oblong frame; I, attached to the arbor; K, a ſlender ſpring on the arbor preſſing againſt the ſtraight tail-piece of the pallet, which paſſes through a hole in the arbor; E, a ſpring ſcrewed to one of the plates of the frame, and preſſing on the tail-piece; F, of the arbor's pivot; and G, a lever with a pin projecting through the dial, with its oppoſite end reaching over the hole of winding, which it covers when the clock is going. The mode of application is thus; when the clock is to be wound up, the pin of the lever, G, is puſhed down a circular aperture of the dial to uncover the hole for the key that is uſed in winding up, which key could not otherwiſe be put into its hole in the dial; the lever, G, being faſt to the front pivot, the arbor, D, turns it a little way round during this motion, for uncovering the key-hole; the tail, F, of the arbor, conſequently is lifted upwards, and with it the ſpring, E, which is the auxiliary ſpring that moves the train by its effort to return the tooth of the pallet, H, is ſo ſhaped, that it will ſlip over a tooth of the ſecond wheel in one direction, but not in the other, without carrying the wheel with it, as may be ſeen from its ſhape in the figure; when, therefore, the pin of G is moved downwards, before winding, a ſmall ſpace, or portion of a revolution of the arbor, D, which bears the pallet and its frame, it carries the end of the pallet next the wheel over a tooth or ſometimes over two teeth; the ſmall ſpring, K, in the mean time allowing the pallet, H, to recede in its frame, I, till it has paſſed the ſaid tooth or teeth; but as the ſpring, K, inſtantly puſhes the pallet into the ſpace next to the tooth it has juſt paſſed, and holds it there, the pallet is urged back again by the auxiliary ſpring E, and carries with it the wheel ſo far that it has room to eſcape from the end of the tooth actuated by it, which eſcape does not take place till ſome time after the clock is wound up: hence the clock continues to go during the period of its being wound up, and when the force of the ſpring is an equivalent for the maintaining power, which it may be made to be when ſtretched back to a certain point; the contrivance will be a convenient temporary ſubſtitute for the maintaining power.

7. *The French Forcing-ſpring.* The forcing-ſpring made uſe of in ſome of the French clocks is ſomewhat different from the one we have juſt deſcribed, and we think more ſimple in its conſtruction, which is this; F A E, in *fig.* 5, of *Plate* XXV., is a rod of metal, moveable on a ſtud ſcrewed into the front plate at A, where is a ſmall tail-piece in contact with a quieſcent ſpring, B, alſo ſcrewed to the ſame plate; at F is a pin in the rod, which comes through a curved aperture in the dial, deſcribed from the point, A, with the radius A F; C is as before the ſecond wheel of the train, or at leaſt a portion of it; D is a pallet moveable on a pin ſcrewed into the ſuperior part of the lever F A E; and E is a ſlender ſpring preſſing againſt the pallet to keep it into the teeth of the wheel; the application of this mechaniſm is in this wiſe; the lever is ſuppoſed to cover the key-hole at ſome point near F, to uncover which the pin, F, is carried upwards towards G in the aperture of the dial; the end, E, of the lever is by this motion brought downwards, and the pallet, D, being curved on the back of it, ſlides over a tooth, or ſometimes two teeth, below it, by its motion on the pin at its upper end, the ſlender ſpring, E, during this time receding; but when the pallet, D, has paſſed the required tooth or teeth, its ſpring, E, puſhes it into the ſpace contiguous, and its ſtraight interior face lays hold of the tooth next above it; in this ſituation the mechaniſm is ready for action, but would remain inactive if the ſpring, B, or auxiliary ſpring, had not at the ſame

fame time been ftretched back by the tail-piece at A; this fpring, B, however, exerts its force to come back to its quiefcent ftate; that is, to bring the pin back again from G to F, its original fituation, and confequently raifes the end, E, with the pallet and pallet-fpring, to its original fituation, which cannot take place without urging the wheel, C, round along with the pallet; this contrivance, therefore, is a fubftitute for the maintaining power, fo long as its action continues; and it is eafy to perceive, that after a few minutes continuance the pallet will efcape the tooth which it impels *pro tempore*, and the maintaining power will then refume the fole command of the train.

8. *The Bolt and Shutter.*—Another contrivance to anfwer the purpofe of making a clock go while it is under winding is the bolt and fhutter, in which a weight is fubftituted for a fpring; *fig. 6*, of *Plate* XXV., reprefents the great wheel and barrel, together with the temporary apparatus, to be fubftituted for the maintaining power thus; the arbor, A, is pivoted into two collars, *a* and *b*, within the frame of the works, in which it is at liberty to revolve; this arbor carries three levers or arms, B, C, and D, all of which are made faft to it, and confequently revolve with it, whenever it is turned round; the lever, B, is juft long enough to extend to the hole in the dial for winding, oppofite the fquare end of the barrel-arbor, which hole it juft covers when in its ftationary fituation, by means of its circular extremity; the lever, C, carries a fmall bolt at its extremity, which is pufhed out by a cylindrical fpring of moderate ftrength, while it is confined to move in the direction of the length of this lever; and D, the third lever, has the weight appended, which is ufed *pro tempore* as a fubftitute for the maintaining power. From this fhort defcription it is eafy to perceive, that, when the clock is to be wound up, the lever, B, muft neceffarily be removed up or down, to allow the key to enter the hole in the dial's face; it is prevented from afcending, and therefore any perfon unacquainted with the nature of the mechanifm, who is going to wind up the clock, finds that he muft pufh down the covering end of B, to gain admiffion for his key; this motion of the lever, B, downwards, pulls down at the fame time the fecond lever C, and alfo elevates the third lever D, which is behind the centre of motion; but the lever, C, cannot defcend till the bolt, which meets with the teeth of the wheel, is pufhed in by them, after which it will pafs; the cylindrical fpring however inftantly pufhes it out again, and makes it fit a fpace between two teeth; in this fituation the weight, D, acting on the third lever, now urges both the levers, B and C, back again to their original fituations, and confequently urges the wheel forwards by means of the bolt, till they have attained thofe fituations; which will require fome minutes when the bolt is applied to the great wheel, according to our figure; but we are of opinion that it would be better to apply the bolt to the centre, or even the fecond wheel, where a fmaller weight would fuffice, and where it would continue to act a fhorter time; for the objection to the bolt and fhutter, as well as to the forcing-fprings juft defcribed, is, that their action continues for fome time after the act of winding in addition to the maintaining power, which therefore it doubles for a time, fuppofing the temporary power to be exactly equal to the permanent one, agreeably to the intention of the contrivance.

CLOCK-*Seaves*, in *Rural Economy*, a term applied to the black-headed bog-rufh.

CLOD, in *Agriculture*, a term frequently applied to a lump of earth, clay, or any other earthly material in a lumpy ftate.

CLODAGH, in *Geography*, the name of a river in Ireland, which rifes in the north-weft angle of the county of Cavan, and paffing by Swanlinbar falls into Lough Erne. It is alfo the name of a fmall river in the King's county which joins the Brofna.

CLODAWA, a town of Poland, in the palatinate of Kalifh; 24 miles E.S.E. of Guefna.

CLODDING-BEETLE, in *Agriculture*, a large beetle, formerly ufed in fome diftricts for breaking the clods in clayey and other ftiff tenacious forts of foil. But at prefent this fort of bufinefs may be much more expeditioufly performed, and at lefs expence, by means of rollers conftructed for the purpofe. See ROLLER.

CLODDY, in *Rural Economy*, a word fometimes applied to cattle, when thick, fhort, or full of flefh. It has the fame meaning as lumpy, when applied to beafts.

CLODEN, in *Geography*, a town of Germany, in the circle of Upper Saxony, and electorate of Saxony; 4 miles S.S.W. of Jeffen.

CLODIA FOSSA, in *Ancient Geography*, a city of one of the iflands of Venice, near the ifland Brendolo. Pliny.

CLODIÆ LEGES, in *Roman Antiquity*, comprehend a variety of laws, enacted by the inftrumentality of the tribune P. Clodius, in order to ferve his own purpofes of intereft or revenge. Thus, it was enacted in the year of Rome 695, 1. That the kingdom of Cyprus fhould be taken from Ptolemy, and reduced into the form of a province. This law was paffed in order to punifh that king for having refufed Clodius money to pay his ranfom, when taken by the pirates, and to remove Cato out of the way, by appointing him to execute this order of the people, that he might not thwart the unjuft proceedings of the tribune, nor the views of the triumviri, by whom Clodius was fupported. 2. That corn fhould be diftributed gratis to the citizens. 3. That no magiftrates fhould take the aufpices, or obferve the heavens, when the people were actually affembled on public bufinefs. 4. That the old companies or fraternities of the city, which the fenate had abolifhed, fhould be revived, and new inftituted. Thefe three laws were paffed with a view of conciliating the attachment of the people. 5. In order to pleafe thofe alfo of higher rank, it was enacted, that the cenfors fhould not expel from the fenate, or inflict any mark of infamy on any man, who was not firft openly accufed and convicted of fome crime by their joint fentence. The true defign of thefe feveral laws was to introduce the banifhment of Cicero; for which purpofe they were enacted; 6. That whoever had taken the life of a citizen uncondemned and without a trial, fhould be prohibited from fire and water. In this law Cicero was not named; but foon after, in an affembly of Clodius's hired flaves and incendiaries, it was exprefsly decreed that he fhould be interdicted from fire and water; that nobody fhould prefume to harbour or receive him on pain of death; and that whoever fhould take any ftep towards recalling him fhould be treated as a public enemy; unlefs thofe fhould firft be recalled to life, whom Cicero had unlawfully put to death. At the fame time it was decreed, with a view of rewarding the confuls Pifo and Gabinius, who had favoured Clodius in his meafures; 7. That the province of Macedonia, with Greece and Theffaly, fhould be granted to the former, and to the latter, Cilicia, which was foon after exchanged for Syria, with a power of making war upon the Parthians; the law enabled them to defray their expences out of the public treafury. In the fame affembly it was further enacted; 8. That the Ælian and Fufian laws, by which the people were left at liberty to tranfact all public bufinefs, even in the days called Fafti, without being liable to be obftructed by the magiftrates, on any pretence whatfoever, fhould be repealed. Thefe laws had been in force about

about 100 years; and Cicero frequently laments the loſs of them, as fatal to the republic; he calls them the moſt ſacred and ſalutary laws of the ſtate; the fences of their civil peace and quiet; the very walls and bulwarks of the republic, which had held out againſt the fierceneſs of the Gracchi, the audacioufneſs of Saturninus, the mobs of Druſus, the bloodſhed of Cinna, and the arms of Sylla. (In Vatin. 9. In Piſon. 4.) 9. Another law was made by Clodius, to give relief to the private members of corporate towns, (municipia) againſt the public injuries of their communities. The real deſign of this ſpecious law was to ſerve a creature of his own, one Merula, of Anagnia, who had been puniſhed or driven from his city for ſome notorious villainies, and who, in return for this ſervice, erected a ſtatue to his patron, on part of the area of Cicero's houſe, and inſcribed it to Clodius, "the author of ſo excelent a law." Among other laws one was enacted, 10. To deprive the prieſt of Cybele, at Peſſinus in Phrygia, of his office, and to ſubſtitute another in his room.

CLODIANA, in *Ancient Geography*, a town of Macedonia, near Dyrrachium. The Itinerary of Antonine places it between Scampis and Apollonia.

CLODIANUS, a river of Spain, in the Tarragonenſis, mentioned by Mela, and alſo by Ptolemy, who places the mouth of it in the country of the Ilercaonians.

CLODII, FORUM. See FORUM *Clodii*.

CLODIUS, PUBLIUS, in *Biography*, a Roman deſcended from an illuſtrious family, and remarkable for his licentiouſneſs, avarice, and ambition. He was ſuſpected of having a criminal intercourſe with his three ſiſters; of whom one was married to Lucullus, the general, under whom he ſerved in Aſia. Diſappointed in his hopes of military rank, he ſucceeded in exciting a mutiny in the army. In the famous conſpiracy of Catiline, Clodius defended the ſenate, and was himſelf one of Cicero's guards. Soon after this he introduced himſelf, by means of female attire, into the houſe of Julius Cæſar, while Pompeia, Cæſar's wife, of whom he was enamoured, was celebrating the myſteries of Ceres. As it was reckoned a very high crime for any male to be preſent at thoſe myſteries, he was accuſed, the next day, by one of the tribunes of impiety and ſacrilege, but either through bribery or intimidation his judges acquitted him. He contrived by the intereſt of Pompey and Cæſar to be choſen tribune of the people, and while he held that office, favoured the ambitious deſigns of thoſe who had aſſiſted him in obtaining it. He procured alſo a decree of the people for the dethroning of Ptolemy king of Cyprus, and Cato, who was a check upon the meaſures of Clodius, was ordered to carry th[illegible] ſentence into execution. Cicero became now the object of Clodius's hatred, and he ſucceeded in driving him into baniſhment, and then cauſed the houſe and villas of the Roman orator to be demoliſhed. Clodius, at this time, uniting himſelf to Cæſar's intereſt, began to inſult Pompey, who in his turn exerted himſelf to procure the recal of Cicero, in which he was not ſucceſsful till the tribune Milo had driven Clodius and his followers from the forum. As ſoon as Cicero was permitted to return, he cauſed all the records of the tribunitial acts of Clodius to be deſtroyed, on the plea that he had been elected to the office contrary to law. In the year, before Chriſt, 53, Clodius was killed by Milo, as he was returning from his country houſe. Cicero undertook the defence of Milo, and endeavoured to prove that the deceaſed had been the aggreſſor for which there was probably no juſt ground, and his client was baniſhed. The attachment of the people for Clodius was exhibited by the burning of Milo's houſe, and making a funeral pile for the body of their hero of the benches of the ſenate. Plutarch. Anc. Univer. Hiſt. Ciceronis Opera.

CLODRA, in *Geography*, a town of Germany, in the circle of Upper Saxony and circle of Neuſtadt; 3 miles E. of Weyda.

CLODY, a river of the county of London-derry, Ireland, riſing in the Carntogher mountains, and joining the river Bann, a little below Portglenone. On it is a village of the ſame name.

CLOERE, a priſon or dungeon; it is conjectured from Britiſh original; the dungeon or inner priſon of Wallingford caſtle, temp. H. 2. was called *Cloere brien*, i. e. *carcer Brieni*, &c.

CLOG. See RUNIC STAFFS.

CLOG, in *Rural Economy*, a word ſometimes applied to a log of wood. It alſo ſignifies a piece of wood faſtened to an animal's foot to prevent its doing miſchief.

CLOGHEEN, in *Geography*, a market and poſt-town of the county of Tipperary, Ireland, on the great road from Dublin to Cork. The ſurrounding country is fertile; and there are ſome good flour mills in and near the town, on a ſmall river that falls into the Suire. It is 93 miles S. W. from Dublin, and 31 N. by E. from Cork.

CLOGHER, a ſmall poſt-town, or rather village, of the county of Tyrone, Ireland, though ſometimes dignified with the name of city, as being the ſeat of a biſhopric, and having before the union returned two members to parliament. There was a rich abbey here, which with its revenues was annexed by James I. to the ſee of Clogher. Some antiquarians ſay that this was a Druidic ſanctuary, and that the ſtone of divination was kept here from which its name is derived, ſignifying the place of the ſtone. St. Patrick is alſo mentioned as the founder of the ſee, before he went to Armagh. The barony to which it gives its name has land of as good a quality as any in Ireland, and is very rich in limeſtone. Clogher is 77 miles N.W. from Dublin. M'Evoy's Tyrone. Dodd.

CLOGHER, an Iriſh biſhopric in the province of Armagh, which ſtretches 60 miles from N.W. to S.E. by a breadth of 20, and compriſes ſome portion of the counties of Donegal, Fermanagh, Tyrone, Monaghan, and Louth. It contains 41 pariſhes, of which only two are united; and there are in theſe no leſs than 49 churches. The cathedral, which is alſo the pariſh church, is a plain handſome modern ſtructure. The biſhop's palace is large, with a remarkably fine park and demeſne. Mr. Young ſtates the income of this ſee to be 4000 *l.* being the next in value to Derry. At preſent it muſt be much more conſiderable. Beaufort. Young.

CLOGHER-HEAD, a cape on the eaſt coaſt of Ireland in the county of Louth. N. lat. 53° 47'. W. long. 6° 12'.

CLOGH-JORDAN, a ſmall poſt-town of the county of Tipperary, Ireland, 70 miles W.S.W. from Dublin.

CLOGHNAKILTY. See CLONAKILTY.

CLOHARS CARNOET, a town of France, in the department of Finiſterre, and diſtrict of Quimperlé; $1\frac{1}{2}$ league S. of it.

CLOISTER, CLAUSTRUM, an habitation ſurrounded with walls, and inhabited by canons, or religious.

In a more general ſenſe, cloiſter is uſed for a monaſtery of religious of either ſex. In a more reſtrained ſenſe, cloiſter is uſed for the principal part of a regular monaſtery, conſiſting of a ſquare built around; ordinarily, between the church, the chapter houſe, and the refectory; and over which is the dormitory, which ſee.

The cloiſters ſerved for ſeveral purpoſes in the ancient monaſteries. Petrus Bleſenſis obſerves, that it was here the monks

monks held their lectures; the lecture of morality at the north side, next the church; the school on the west, and the chapter on the east; spiritual meditation, &c. being reserved for the church.

Du Cange concludes, that all these different exercises were performed in the cloister itself; but by mistake.

The church, the chapter-house, and the school, were not parts of the cloister, but buildings adjoining to it.

Lanfranc observes, that the proper use of the cloister was for the monks to meet in, and converse together, at certain hours of the day.

The form of the cloister was square; and it had its name *claustrum* from *claudo, I shut, or close*, as being inclosed on its four sides with buildings. Hence, in architecture, a building is said to be in form of a cloister, when there are buildings on each of the four sides of the court.

CLOISTERED MONKS. See MONK.

CLOLUGH, in *Geography*, a river of Ireland, which rises in the Commeragh mountains, in the county of Waterford, and passing by Curraghmore, runs into the Suire. Pearl-muscles are found in this river. Smith's Waterford.

CLOMANNORUM *Civitas*, in *Ancient Geography*, a town of Asia, towards Babylonia.

CLOMPANUS, in *Botany*, minor and major: Rumph. See STERCULIA.

CLONAKILTY, or CLOGHNAKILTY, in *Geography*, a market and post-town of the county of Cork, Ireland. It was incorporated by the interest of the first Earl of Cork in 1605, and sent two members to parliament before the Union. It is situated near the sea, but this, says Dr. Smith, affords it more pleasure than profit, as the mouth of the harbour, being choaked with sand, prevents vessels of burden from coming to it. M'Kenzie describes this harbour as fit for small vessels only; and very dangerous sailing in or out, when the wind is at the southerly quarter. There is a pretty good market for linen yarn and coarse linens, which is attended by the Bandon merchants. In the neighbourhood is a mine, which contains some good lead ore, of the kind called galena, and abundance of black blende; but the working of it was soon dropped, from want of sufficient capital to proceed, as it was not immediately productive. Clonakilty is 145 miles S. W. from Dublin, and 22 miles S.W. from Cork. N. lat. 51° 37'. W. long. 8° 42'. Smith. M'Kenzie.

CLONARD, a post-town of the county of Meath, Ireland. It was formerly of some importance, having been a bishop's see, which was consolidated with several others in 1152, this being the residence of the bishop; but in 1216, they were formed into the present see of Meath. There was an abbey here, the ruins of which show it to have been extensive, and the endowments of which were great. The old town is now gone to decay, and the new one which has a bridge over the Boyne, is a place of no trade. It is 26 miles W. from Dublin, on the road to Mullingar, and very near the place where the royal canal crosses the Boyne. Thompson's Meath, &c.

CLONEGALL, a small post-town of the county of Carlow, Ireland, on the confines of Wexford, 47 miles S. by W. from Dublin.

CLONES, a market and post-town of the county of Monaghan, Ireland, the weekly sales of linens at which is estimated at 700*l.*, and its other trade thriving. There are ruins of two or three religious buildings in and near this town. It is 62 miles N.W. from Dublin.

CLONEY, a small lake in Glaneroughy Kerry, about ten miles from Nedeen, and communicating with Kenmare river, which is said to possess all the charms of Killarney in miniature. Beaufort.

CLONFERT, an Irish bishopric, under the metropolitan see of Tuam. It was founded near the close of the sixth century, and was united to the see of Killmacduagh in 1602. There are in this united see sixty parishes, all of which, except three, are in the county of Galway. These are by unions reduced to fifteen benefices, and fourteen of them have churches. The cathedral and parish church are the same, and the bishop has a palace in the neighbourhood; but Clonfert is so small as not to deserve even the name of a village. Beaufort.

CLONIA, in *Ancient Geography*, a marsh of Africa, in Interior Libya, near mount Risadius. Ptolemy says that the marsh is formed by the river Stachir.

CLONMACNOISE, or CLUAIN-MAC-NOIS, i. e. *the retirement of nobles*, in *Geography*, a place in the King's county, Ireland, once the see of a bishop, and at present remarkable for the extent of its monastical ruins. An abbey was founded here by St. Kiaran, in 548, which afterwards became a cathedral; this presided over nine other churches, in one church-yard, as it were, for they were within less than the compass of two Irish acres; and at the west end of this space the bishop's palace was erected. It was situated on the banks of the Shannon, ten miles from Athlone, raised above the river on ground composed of many small elevations. The abbey, which belonged to the regular canons of St. Augustine, was peculiarly and universally esteemed, was uncommonly extensive, and was enriched by many kings and princes. Its landed property was so great, and the number of cells and monasteries subjected to it so numerous, that almost half of Ireland was said to be within its bounds. This was also the *Iona* of Ireland, where the princes of the country were buried; and it was imagined that all who were interred there had insured an immediate ascent to heaven. Several of the churches are supposed to have been erected as places of sepulture. Yet, notwithstanding the opinion of its sanctity, the abbey was often plundered and destroyed by despoilers of every kind, by the unpolished Irish desperado, by the barbarous Ostmen, and, with concern it is added, by the English settlers. These, who ought to have conciliated the affections of the natives, and set them an example of obedience to the laws, and of a peaceable demeanour, too often joined in the greatest outrages, and, amongst other transactions of a like kind, repeatedly disturbed the retired seminary of Clonmacnoise. In 1568 the see was united to Merth by act of parliament, and the deanery alone remains of the ancient chapter. There are remains of several churches, and one is still used as the parish church. There are also two round towers. They are now surrounded by extensive bogs, and the appearance of the country is wild and uncultivated. Ware. Archdall's Monast. Hibern.

CLONMELL, a market and post-town of the county of Tipperary, Ireland. It is the shire town, large and opulent, where the woollen and cotton manufactures were formerly in a flourishing state, but, as in other places, have declined. Though very inconveniently situated for the assizes, at the extremity of so large a county, it is admirably seated for trade, on the banks of the Suire, which is so far navigable for large boats, the tide flowing a little way above the town. The adjoining country is uncommonly fertile, and there are in and near Clonmell a number of boulting mills, from which flour is sent to Dublin. The county-court house is a new and handsome building; and the jail, which is also of late construction, was built on Mr. Howard's plan. Clonmell was formerly a place of strength, and was able to make some stand against Cromwell, who besieged it in person. Before the

the Union it ſent two members to the Iriſh houſe of commons, and has at preſent one repreſentative in the Imperial parliament. It is 84 miles S.W. from Dublin; N. lat. 52° 21′. W. long. 7° 43′. Beaufort, &c.

CLONMINES, a village of the county of Wexford, on an arm of the ſea, not far from the place where Strongbow landed. Some ruins bear teſtimony to its former importance, and until the Union it ſent two members to parliament. It is 81½ miles S. from Dublin, and about 15 W. from Wexford.

CLONTARF, a village in the county of Dublin, Ireland, on the ſtrand between the city of Dublin and Hoath. It is much frequented for ſea bathing, and is a pleaſing object to thoſe entering the harbour. Clontarf is remarkable in the hiſtory of Ireland for a battle fought, in the year 1014, between the Danes, or Oſtmen, and the Iriſh, in which Brien Boronche, who commanded the latter, loſt his life, though his troops gained a deciſive victory. It is 3 miles from Dublin.

CLOPPENBOURG, a town of Germany, in the circle of Weſtphalia, and biſhopric of Munſter, the principal place of a bailiwick; 64 miles N.N.E. of Munſter. N. lat. 52° 53′. E. long. 7° 35′.

CLOSE, a term in *Heraldry*, uſed to expreſs the wings of the eagle, falcon, kite, &c. being kept cloſe to their bodies, but muſt not be uſed to the peacock, dunghill-cock, or any others not addicted to flight. It is alſo applied to a helmet with the vizor down.

CLOSE, in *Muſic*, ſimply means an end or termination to a movement, vocal or inſtrumental. See CADENCE, CADENZA, COUNTERPOINT, and COMPOSITION. But ſince the eſtabliſhment of the opera, or muſical drama, and ſingers of great abilities, taſte, and execution, have been employed and frequently left to themſelves, *ad libitum*, at a pauſe, or at the concluſion of an air, by a cloſe or cadenza is underſtood ſuch an extemporaneous effuſion of taſte and fancy, terminated by a ſhake, as could be executed in one breath. See Toſi, chap. viii. p. 126, and Italian Tour; Reflections on the length and abuſe of cloſes.

Long cloſes were a nuiſance in Italy thirty years ago. When it was obſerved that at Rome, Criſtofero, who ſung in Guarducci's poliſhed manner, though his cloſes were excellent, full of fancy and good taſte, yet they appeared too long; this fault was then general throughout Rome and Naples, where ſuch a long-winded licentiouſneſs prevailed in the cadences of every ſinger, as was always tireſome, and often diſguſting; even thoſe of great performers needed compreſſion, and thoſe made by performers of an inferior claſs, not only wanted curtailing, but correction. A few ſelect notes, with a great deal of meaning and expreſſion given to them, is the only expedient that can render a cadence deſirable, as it ſhould conſiſt of ſomething ſuperior to what has been heard in the art, or it becomes impertinent. This abuſe in making cloſes is not of very ancient ſtanding, for in a ſerious opera of old Scarlatti, compoſed in 1717, there is not a ſingle place for a cadence, *ad libitum*, to be found. But, to length is now added another complaint, by that part of an audience who have heard the great performers of former times; which is, the taking breath, ſometimes even more than once, before the concluding ſhake is made, after which the performer expects to be "welcomed home."

CLOSE, in *Rural Economy*, a ſmall incloſed field or paddock. A ſmall incloſure of any kind.

CLOSE-*Feeding*, the practice of eating graſs herbage down in a cloſe or bare manner, by ſheep or other animals. It is of much conſequence to the grazier, to have his paſtures kept in a ſtate of cloſe-feeding, as the animals are found to do much better under ſuch circumſtances: and at the ſame time to be capable of ſupporting a larger proportion of ſtock. Speaking of cloſe-feeding, Mr. Young has given the following uſeful remarks. "In the preceding trials there was not, through the thirty weeks, ſcarcely a bent to be ſeen; the paſturage was conſtantly ſhorn to the ground, and in that ſtate it was remarkable to ſee how conſtantly, and even rapidly, it ſprung, during the continuance of a drought that was deſtructive of all produce in fields on the ſame farm, ſuffered to run to bent, for hay or other views. The compariſon was the moſt deciſive that can be imagined. He had many fields, better than any there regiſtered, that yielded ſo contemptible a produce of hay, as to be ſcarcely worth mowing; and he was amazed to ſee in ſome of them how poor the *rouen* or after-graſs was, ſo that both united, or the entire growth of at leaſt forty weeks, has amounted not to the fourth of the value of the produce of ſimilar ſoils pared cloſe by ſheep." And he adds, "a Romney-marſh grazier would be ruined if he had ſo much graſs on his land," ſays Mr. Boys, in his Farming Tour, ſpeaking of a field underſtocked."—Annals, vol. xix. p. 118. "Nothing ſo bad," ſays another, "in Romney-marſh, as mowing, ſo that ſome landlords prohibit it." Pliny, ſays Mr. Young, knew this.—*Eſt enim in primis inutile, enaſci herbas ſementaturas.* Plin. Hiſt. Nat. lib. xviii. cap. 28. And of the fact he has not the leaſt doubt, from various experiments and obſervations; and there is no man but has remarked it, he thinks, in the caſe of ray-graſs, the produce of which is loſt if the bent be allowed to riſe. In all plants cultivated for paſturage, there is a great effort the moment the ſeed-ſtem runs, to which the whole growth of the plant is directed to form the ſeed; till then the growth is in the leaves: it is therefore palpable, that the way to have the greateſt abundance of leaf, is by feeding ſo cloſe as to prevent thoſe ſtems riſing at all. And he may further obſerve, that, on this ſyſtem of feeding, thoſe graſſes which yield a very great but coarſe produce, become ſweet, fine, and valuable, by thus keeping them cloſe fed. The *avena elatior*, or tall oat-graſs, is very coarſe, but in a field of that graſs, thirteen acres and half, it never was ſuffered to riſe, and conſequently was found, on examination, to appear as fine and pleaſing to the eye as any of the more delicate graſſes. It is with this view that he is cultivating it largely, and alſo the *dactylus glomeratus;* and both are remarkably early."

He ſuggeſts it as "an inquiry that deſerves attention, whether the ſuperior profit of grazing ſheep, on compariſon with oxen, does not depend very much on this point of cloſe feeding: for large cattle, the herbage muſt be kept to a good head to give a full bite; and conſequently innumerable ſeed-ſtems form, which tend to reduce the produce greatly." There can be no doubt of the great benefit and advantage of cloſe-feeding, in all ſtates where the lands are covered with a coarſe graſſy turf or ſward. See PASTURE and GRAZING.

CLOSE-*Teap*, a term ſometimes provincially applied to a ram, or male ſheep, where both the teſticles are within the barrel of the animal.

CLOSE, *Breach of*, in *Law*, a ſpecies of treſpaſs, denoting every unwarrantable entry on another's ſoil, which the law ſuppoſes to be *incloſed*, either by a viſible fence, or an inviſible boundary. Accordingly, the words of the writ of treſpaſs command the defendant to ſhew cauſe, "quare clauſum querentis fregit." Every ſuch entry, or breach of a man's cloſe, carries neceſſarily along with it ſome damage or other; for, if no other ſpecial loſs can be aſſigned, yet ſtill the

the words of the writ itfelf fpecify one general damage, *viz.* the treading down and bruifing his herbage. F. N. B. 87, 88. See TRESPASS.

CLOSE-*Rolls*, and CLOSE *Writs*, charters, or letters of the king, containing grants of lands, &c. fealed with his great feal, and directed to particular perfons, and for particular purpofes, which, not being proper for the public infpection, are *clofed* up and fealed on the outfide, and are therefore called *writs clofe*, *literæ claufæ*, and they are recorded in the *clofe rolls*. See LETTERS, and PATENT.

CLOSE *Field*. See FIELD.

CLOSE *Fights*, aboard a fhip, are bulk-heads put up fore and aft in the fhip, for the men to ftand behind in a clofe engagement, and fire on the enemy; or, if the fhips be boarded, to fcour the decks.

CLOSE *Fire*. See FIRE, and REVERBERATION.

CLOSE-*hauled*, in *Sea Language*, denotes the arrangement or trim of a fhip's fails when fhe endeavours to proceed in the neareft direction poffible to that point of the compafs from which the wind blows. The keel of larger fhips makes an angle of about fix points with the line of the wind: but floops and fmaller veffels fail almoft a point nearer. All veffels, when clofe-hauled, make nearly a point of lee-way, and this angle increafes with the increafe of wind and fea. The fails, in this difpofition of them, are all extended fideways on the fhip; and the term *clofe hauled* is then applied to it, becaufe her tacks are drawn clofe down to her windward fide, the fheets hauled clofe aft, and all the bow-lines are drawn to their utmoft extenfion, in order to keep the fails fteady.

CLOSE *Quarters*, denote ftrong beams of wood extended along a merchant-fhip in feveral places; as they are a place of retreat, when the fhip is boarded by an adverfary, they are fitted with fmall loop holes, through which the fhip's crew may fire fmall arms to defend themfelves, and annoy the enemy. They are likewife furnifhed with powder-chefts, filled with powder, old nails, &c. which may be fired upon the boarders.

CLOSE *Pound*. See POUND.

CLOSET, in *Heraldry*, is the diminutive or half of the bar.

CLOSET, *Clerk of the*. See CLERK.

CLOSET, *Water*, in *Architecture*. See WATER-*clofet*.

CLOSH, in our old cuftoms, an unlawful game, forbidden by ftat. 14 Edw. IV. c. 3. and 33 Hen. VIII. c. 9. It is faid to have been the fame with our *nine-pins*, and is called *clofh-coyls* by the 33d. Hen. VIII.

CLOSTER NEWBURG, in *Geography*, a town of Germany, in the archduchy of Auftria; 11 miles N.N.W. of Vienna.

CLOSTER-SEVEN, a town of Germany, in the circle of Lower Saxony, and duchy of Bremen, famous for a convention or capitulation, called the treaty of Clofter-feven, by which the duke of Cumberland, commanding 38,000 Hanoverians, was obliged in 1757 to furrender to the French under the duke de Richelieu, and to lay down their arms. It is diftant 19 miles S. from Stade, and 24 N.N.E. from Bremen.

CLOSTERMAN, or KLOOSTERMAN, N., in *Biography*, a portrait painter, who was born at Hanover in 1656, and was much efteemed in his time. It is not known from whom he firft received inftructions, but he came to London in 1681, and for fome time affifted Riley in the draperies and other acceffoiial parts of his pictures. After the death of his mafter, Clofterman got into vogue, and was employed to paint the portraits of many of the principal nobility.

In the year 1696, he was invited to Madrid to paint the king and queen of Spain, together with the principal grandees of the court; he returned, loaded with riches and honour, to England; foon after which he painted a whole length portrait of queen Anne in her robes, a rich and ftriking picture, which was afterwards placed in Guildhall. He died in the year 1713, aged 57, having previoufly to his death been robbed of all his hard-earned wealth by an infidious miftrefs. Defcamps. Pilkington.

CLOSTRA, in *Ancient Geography*, a maritime place of Italy, between Antium and the promontory of Circé.

CLOT-*Bird*, in *Ornithology*, a name by which the common OENANTHE is called in many parts of England.

CLOTAIRE I. king of France, in *Biography*, was the third fon of Clovis, by his wife Clotilda, and born A. D. 497. When he was only 14 years of age, he inherited as his patrimony the kingdom of Soiffons. In 516, he united with two of his brothers in declaring war againft Sigifmond, king of Burgundy, and his brother Gondimar. The latter they put to flight, but Sigifmond, with his wife and children, they took prifoners. In this expedition Clodimir, one of the three, was killed, having firft caufed the king of Burgundy to be deftroyed, and Clotaire, with his brother Thierri, took poffeffion of his dominions as guardians to the fons of the unfortunate monarch. They afterwards invaded Thuringia, in which Clotaire fhewed great military prowefs, but from certain jealoufies that fubfifted between the brothers, he narrowly efcaped affaffination at a conference. Clotaire and his brother Childebert feized their nephews, the fons of the deceafed Clodimir, two of whom the favage Clotaire ftabbed with his own hands; and the third efcaping, he caufed all the tutors and even domeftics of the young princes to be facrificed at the fhrine of his mad ambition. Clotaire and Childebert invaded and ranfacked the Italian territories of the Romans and Oftrogoths. In 543 they attacked Spain, and penetrated as far as Saragoffa, but on their return with confiderable booty, they were defeated and plundered by the Goths. The death of Thierri placed the fceptre wielded by that monarch in the hands of his natural fon Theobalde; and on the demife of that prince, his fubjects agreed to acknowledge Clotaire as their fovereign, who, by the fubfequent deceafe of Childebert, united the dominions of Clovis under his fole government. Clotaire was not permitted long to enjoy in peace his ill-gotten power and dominion. His eldeft fon, Chramnes, twice took up arms againft him, but being defeated, and compelled to feek for mercy, he was once reftored to favour, but the fecond time Clotaire ordered his fon with his wife and children, to be burnt to death in his prefence. As an atonement for crimes of which his own confcience muft have been a perpetual monitor, the bloody Clotaire made very confiderable prefents to the church, which he frequently accompanied with fuch acts of devotion as the ignorance of the times prefcribed. He died in the year 561, having reigned fifty-one years. He had been married to fix wives, and left four fons, who divided his kingdom among them.

There were three other princes of France of the fame name, of whom we fhall only notice the fecond.

CLOTAIRE II. was but four months old when he fucceeded to his father Chilperic's kingdom. In his youth he fpent much of his time in warfare, and by his conduct to his kinfmen, two of whom he caufed to be murdered, he fhewed himfelf entitled to the name of Clotaire. When, however, he had gained the great object of his ambition, and was become the fole monarch of the Franks, he feemed anxious to atone for his former cruelties by the exercife of a

mild

mild and juſt government. He ſubmitted the civil and eccleſiaſtical affairs of his kingdom to a council compoſed of people celebrated for their high rank and attainments in wiſdom. He inſtituted a kind of parliaments in his own palace, the powers of which, though not now to be clearly aſcertained, were probably exerciſed for the benefits of the people. Clotaire attained to conſiderable celebrity as a warrior. In 627 he routed the Saxons, who had revolted from him, on the banks of the Weſer, with great ſlaughter. The next year he died in the height of reputation, having acquired the titles of the *Great* and *Debonair*. Du Freſnoy. Hiſt. Univer. Hiſt. de France.

CLOTH, in *Commerce*, in its general ſenſe, includes all kinds of ſtuffs woven or manufactured on the loom, whether their threads be of wool, hemp, or flax.

CLOTH is more peculiarly applied to a web, or tiſſue of woollen threads interwoven; whereof ſome called the *warp*, are extended lengthwiſe, from one end of the piece to the other; the reſt, called the *woof*, are diſpoſed acroſs the firſt, or breadthwiſe of the piece.

CLOTHS, *Superfine*; the beſt of theſe are made entirely of Spaniſh wool; the fineſt ſorts of which are the Leonera and Segovia.

Of Engliſh wools, thoſe of Hereford and Suſſex approach the neareſt in fineneſs to the Spaniſh, and from the choiceſt of theſe are manufactured ſuperfines of an inferior ſort. From the reſt of the Engliſh wools are made the ſeconds, liveries, and coarſer cloths, varying in price according to their qualities.

The goodneſs of cloth conſiſts, 1ſt. In the fineneſs of the wool. 2d. In the clearneſs, richneſs, and beauty of the colour. 3d. In its being evenly ſpun, always obſerving that the thread of the warp be cloſer twiſted, and one-fourth part ſmaller than that of the woof. 4th. In the cloth's being well wrought and beaten on the loom, ſo as to be in every part equally cloſe and compact. 5th. In being milled or fulled evenly, clean ſcoured, and of a proper thickneſs or ſubſtance. 6th. In being well dreſſed, ſo that the hair or knap of the wool be fully and evenly drawn out and ranged on the ſurface, and in being ſhorn cloſe, yet without laying the ground or threads bare. 7th. In its not being overſtretched in the rack, or pulled farther than is neceſſary to ſet it ſmooth, and bring it to its juſt length and breadth. Laſtly. In the cloth itſelf appearing ſmooth and neat on the face, free from ſmall knobs, ſpots, and other imperfections; in being firm yet pliable, and feeling ſoft and fine to the touch.

CLOTH, *manufacture of*. A detail of the manner in which ſuperfine cloths are manufactured in Wiltſhire, may ſerve for the whole; the inferior ſorts differing little, but in the coarſer and leſs delicate modes of performing the ſame operations.

It is previouſly to be obſerved, that all the cloths which are deſigned for ſcarlets, greens, and blacks, as well as many of the moſt lively and delicate colours, are manufactured white, and dyed in the piece after they are finiſhed.

The wool, being taken out of the bale, muſt firſt be picked, to clear it from the pitch which adheres to it, and from the other extraneous ſubſtances with which it abounds. It muſt then be ſcoured, by putting it into a furnace containing a liquor compoſed of three parts of water, and one of urine. After it has been well ſtirred about therein, and the greaſe it contains diſſolved, it muſt be taken out, drained, and waſhed in running water, and in that ſtate it is fit to be committed to the dye-furnace.

After dyeing it muſt be again waſhed and well dried, when it muſt be beaten with rods on wooden hurdles, to free it from the dye-ſtuff, which ſtill hangs about it; or elſe the ſame effect is produced by putting it into a wool mill, formed of a four-flapped vane or fan thinly ſet with iron ſpikes, and ſwiftly revolving within a hollow cylinder, compoſed of ſmall wooden rods or ſtaves, ſufficiently wide apart to ſuffer the duſt to fall through, as the wool becomes ſlightly ſeparated by the motion of the fans. It is then once more carefully picked, in order to take out the locks which are unevenly dyed, and alſo the lint, and other filth with which wool in this ſtate generally abounds.

In making mixed cloths, wool of the different colours, being weighed out in their requiſite proportions, are firſt ſhaken well together; they are then further mixed by being well turned in the wool mill, and by being afterwards *twice* paſſed through the ſcribbling engine inſtead of *once*, they are generally found to be ſufficiently intermixed.

The wool, thus prepared, muſt now be ſpread abroad on a floor, and oil of olives (in the proportion of 3lb. to 20lb. of wool), evenly ſprinkled over it, and beat into it with heavy rods, when it is in a proper ſtate to be carried to the ſcribbling engine.

This is a machine compoſed of ten or more wooden cylinders, of various ſizes, covered with cards, the teeth or wire of which are of different degrees of fineneſs, and bent or hooked in oppoſite directions. Theſe are combined in a ſtrong wooden frame, and ſo fitted as juſt to touch and work againſt each other, as they ſwiftly revolve on being ſet in motion by a common handle, adapted to be turned either by men's labour, or any ſort of mill work. By paſſing through this engine, the locks of wool, which before were cloſe and matted together, are drawn abroad, the fibres are ſeparated, and it is formed into light flakes; it is then taken to the carder, which is a ſmaller engine of the ſame kind, only covered with finer cards, and with the addition of a fluted roller revolving in a trough at the tail of the machine; by which the wool, after being ſtill finer and better mixed and carded, is formed, as it drops out, into ſeparate and ſmooth rolls of 28 inches long, and half an inch in thickneſs, which are immediately taken by boys, and joined or attached to the ſpindles of the roving or ſlubbing machine.

This is a contrivance, by which 50 or more iron ſpindles, being ſet upright in a wooden frame, are twirled by one motion, yielding their threads to a common ſlider, at every move of which the 50 rolls of wool are drawn out and formed into as many large ſlightly twiſted threads, and at the ſame time wound off into balls of a ſize and ſhape adapted to the next operation, or ſpinning.

This is performed by a machine called the *ſpinning jenny*, which alſo is a frame containing 70 or more upright ſpindles, twirled like the former by a common motion, and yielding their threads to one and the ſame ſlider; by this the large hollow threads are further twiſted and drawn out to the degrees of ſmallneſs and ſtrength requiſite for the different purpoſes for which they are deſigned. The threads, being thus ſpun, are reeled into ſkains and prepared for the loom. The larger ſort, deſtined for the woof, is wound on ſpools, which are ſmall tubes, ſo formed as to be eaſily placed in the eye or hollow of the ſhuttle. That for the warp is wound on large wooden bobbins, from which, by the warping bar, it is conveniently formed into the proper lengths and diviſions, and ſo arranged and diſpoſed as to form the chain or warp of the piece.

The chain, thus prepared, muſt be ſtiffened by a ſize, which is made by diſſolving 3lbs. of glue (the beſt ſort of which is made from ſhreds of parchment) in a quantity of water ſufficient to moiſten and ſaturate the whole, and when dried it is ready to be turned on the loom.

In weaving broad-cloth, there are two weavers in a loom, one on each ſide, who at the ſame time tread alternately on the ſame treadle, *i. e.* now on the right ſide and now on the left, which raiſes and lowers the threads of the warp equally, between which they throw, tranſverſely, the ſhuttle from the one to the other. At each time that the ſhuttle is thrown (and ſo a thread of the woof inſerted within the warp), they ſtrike it conjointly with a moving frame, wherein is faſtened the ſlay, which is a kind of comb, compoſed of thin pieces of cane, between whoſe teeth the threads of the warp are paſſed, repeating the ſtrokes ſix or ſeven times with the warp open, and again as many times after it has croſſed and cloſed on the woof. The whole warp being filled with woof, the cloth is finiſhed.

Being next taken to the fulling-mill, it is there ſoaked with urine or hog's dung, and afterwards ſcoured with clean water; it is thus freed from the oil and filth contracted in dyeing, and delivered perfectly clean, in a ſtate fit for the next operation, which is burling.

By this proceſs (performed by women with little iron nippers) the cloth is cleared from all the knots, lint, ſmall ſtraws, and leſſer filth; and if, by the careleſſneſs of the ſpinner, it contains any large uneven threads, they muſt now be gently taken out; and if any ſmall hole or rent is made, it muſt be carefully drawn up, and mended with ſome of the warp-yarn of the ſame cloth.

But that compactneſs and denſity which diſtinguiſh woollen cloth from all other manufactures, and renders it ſo peculiarly adapted to our wear in theſe northern climates, are derived from the next operation, which is fulling, or milling, by which a cloth of 40 yards long, and 100 inches wide, being firſt ſprinkled over with a liquor prepared from 5lbs. of fine ſoap (made from the oil of olives) diſſolved in hot water, is laid in the mill-trough, and there pounded or ſtamped on by two heavy wooden hammers, alternately raiſed and depreſſed by the cogs of a mill-wheel. By this proceſs it becomes by degrees (generally in about 8 hours) ſo thickened and ſhrunk up, as to be reduced to 30 yards long and 60 inches wide, which renders it of the proper ſubſtance and thickneſs of common ſuperfine cloth. During this operation, it muſt be taken out from the trough from time to time, to have more ſoap added, and to be ſmoothed from the wrinkles and creaſes which it would otherwiſe contract.

This faculty of being rendered thicker by compreſſion, is peculiar to woollen ſubſtances. In vain may fabrics of ſilk or cotton be ſubjected to the ſame proceſs; they would not, in any length of time, be rendered thicker by it, or more compact in the ſmalleſt degree. To account for this, it has been obſerved, that the ſingle hairs of wool, when viewed in a microſcope, are diſcovered to be thickly ſet with rough and jagged protuberances, adapted to catch and entangle with each other. Whence it ſeems probable, that during the violent agitation the cloth undergoes in the mill-trough, the fibres being, at every ſtroke of the mill hammer, ſtrongly impelled together, and driven into the cloſeſt poſſible contact, at length hook into each other, drawing cloſer and cloſer as the proceſs continues, till they become thus firmly and inextricably united; each thread, both of the warp and the woof, being ſo joined and compacted with thoſe that are contiguous to it, that the whole ſeems formed into one ſubſtance, not being liable, like other fabrics, when cut with ſhears, to unravel and become ragged at the edges.

The cloth, thus milled to its proper thickneſs, muſt be ſcoured with clean water till it be perfectly free from the ſoap. In this part of the proceſs, a preparation of fullers-earth and bullock's gall is found very ſerviceable, rendering the cloth at the ſame time ſoft and mellow.

The cloth muſt now be taken to the cloth-worker, in order to be dreſſed, which is performed by firſt properly drawing out, and arranging in one direction, all the hairs or fibres of the wool that can poſſibly be brought to the ſurface, and then ſhearing it as cloſe as it will admit, without diſcovering the ground of the cloth, or laying the threads bare.

The inſtruments employed in this operation, are the wire cards, and teazels, to raiſe and draw out the hair, and the ſhears to cut off what is too long and ſuperfluous. (The teazel is a large kind of thiſtle, with the points growing very ſtrong and hooked; to uſe them the heads are cut off, and ſet cloſe together in ſmall wooden frames called *handles.*) Theſe inſtruments, although hitherto worked by men's hands, with great labour and expence, have of late been ſo ingeniouſly adapted to machinery turned by mill-wheels, as to perform the ſame operations with much more preciſeneſs and effect, as well as great ſaving in point of expence; and the machines for this purpoſe are various, and continually improving. The method hitherto employed is generally as follows.

The cloth being drawn over a frame, conſtructed of boards laid ſloping, and covered with hair-cloth, is, during its paſſage, in order to raiſe the wool, regularly ſcraped, or rubbed from one end to the other, with the cards or teazels, being all the time kept as wet as poſſible by continually pouring water upon it. It is then laid on the ſhearing boards, which are made of wooden planks covered with coarſe cloth, and forming a kind of hard cuſhion, where the wool thus raiſed is cut off with long heavy ſhears, which are preſſed cloſe to the cloth with leaden weights, and gradually ſlide forward at every motion or cut, till they have proceeded from one liſt to the other. The cloth is then returned to be again ſcraped or rubbed; theſe operations are repeated three times, every time with finer cards, or teazels, when the wool becomes ſufficiently raiſed. It muſt now be taken to the rack, on which being faſtened by the liſts with ſmall hooks or tenters, it muſt be drawn or ſtrained thereon, until it be of an even breadth throughout; when dry it is returned to the ſhearing boards, on which the cutting is repeated three times more on the right ſide, and once on the other or back ſide. After this it is given to the cloth-drawers, who, having firſt, with ſmall picking irons, made very ſharp at the points, drawn out all the ſmall ſtraws and bits of lint which have before eſcaped notice, carefully fine-draw or mend the ſmall holes or rents, if any ſuch have been made in it.

Nothing now remains to be done but preſſing; preparatory to which, the cloth being doubled and laid in even folds, a leaf, or ſheet of glazed paſteboard, is inſerted between each fold or plait of the cloth; it is then laid in the preſs, and covered with thin wooden boards or fences, on which are laid iron plates properly heated, and on the whole (by means of a lever turning a ſcrew) the top of the preſs is brought down, with the degree of force judged neceſſary to give it the proper gloſs. When cold, it may be taken out of the preſs, in order to be folded and packed, ready for ſale.

The ſtatute book contains a variety of laws relating to the *woollen manufacture*; the principal of which will be recited under that article: we ſhall here ſubjoin an account of the moſt important laws pertaining to cloth and clothiers. Every fuller of cloth ſhall uſe tayſels, or teazels, and no cards, deceitfully impairing the ſaid cloth, on pain of double damage, to be determined by a juſtice of the peace, mayor, maſter, warden, bailiff, portreeve, conſtable of hundred, and ſteward of leet, who may commit the offender to the next gaol till payment; information may be made by any perſon not grieven to any of the above magiſtrates or officers; and the offender

ſhall

ſhall forfeit to the king, or to ſuch perſons as ſhall be intitled to fines or amercements within their juriſdiction, 3*s.* 4*d.* 4 Edw. IV. c. 1. No cloth, not fulled, ſhall be exported, on pain of forfeiting the ſame, half to the king and half to him that will ſue. 7 Edw. VI. c. 3. For the meaſuring of cloth, the ſtatutes generally provide that the yard ſhall conſiſt of a ſtandard yard, and the breadth of a man's thumb; or 37 inches in the whole. In every pariſh or hamlet where cloths are made, two juſtices ſhall appoint overſeers for taking care that the ſtatutes relating to the regulation of cloth be obſerved. 3 and 4 Edw. VI. c. 2. 39 Eliz. c. 20. 43 Eliz. c. 10. Theſe overſeers are empowered to ſearch or try the cloth, and perſons refuſing or reſiſting ſearch ſhall, on conviction at the ſeſſions, forfeit for the firſt offence 10*l.* for the ſecond 20*l.* and for the third, ſtand upon the pillory in the next market town; of the forfeitures one third ſhall belong to the overſeers, one third to the king, and one third to the poor. 39 Eliz. c. 20. The length, breadth, and weight of the ſeveral ſorts of cloth are ſettled; allowance in weight, for dyeing, dreſſing, roving, and chaſing, in broad cloth 4lbs. in long cloth 5lbs. and ſo in proportion, is adjuſted, and an increaſe of weight by any liquid is forbidden on pain of 40*s.* half to the king, and half to the buyer that ſhall ſue, by 4 Jac. I. c. 1. c. 2. Before ſale the maker ſhall fix his ſeal of lead to the ſame, containing the length and weight, to be tried by the water, and the overſeer ſhall fix ſuch ſeal to the cloth, with the word "ſearched." 39 Eliz. c. 20. On the penalty of his recognizance he ſhall ſet his chriſtian and firname upon the ſeal, and no other ſhall be good. 21 Jac. c. 18. Any perſon ſetting any ſeal to cloth, or taking any ſeal away, without warrant, ſhall on conviction at the ſeſſions, for the firſt offence forfeit 10*l.* for the ſecond 20*l.* and the pillory; one third of the forfeitures to the overſeers, one third to the king, and one third to the poor. Cloth offered to be ſold unſealed ſhall be ſeized by the overſeers. 39 Eliz. c. 20. For each of the cloths under the ſealed meaſure in length, 6*s.* 8*d.* per yard ſhall be forfeited, beſides abatement of the price for what is wanting; for every yard of the ſaid cloth above the lengths, 10*s.* ſhall be forfeited; and for the ſame wanting breadth throughout, ſhall be forfeited 20*s.* wanting for half the length 10*s.* under half, 5*s.*; and for every pound wanting above 2lbs. in weight ſhall be forfeited 10*s.* Jac. c. 20. For the encouragement of dreſſing and dyeing of cloth, no perſon ſhall export any white woollen broad cloth, until he have paid duty of 5*s.* for every ſuch cloth, on pain of forfeiting the ſame, or value; half to the king, and half to him that ſhall ſeize, inform, or ſue. 6 Ann c. 8. The legiſlature has enacted other laws with regard to dyeing of cloth, for which ſee Dyeing. No perſon ſhall have or uſe any tenter, with a lower bar, &c. for ſtretching any rough and unwrought woollen cloth, on pain of 20*l.* half to the king, and half to him that ſhall ſue. No perſon ſhall ſtretch (or ſell the ſame ſtretched) any wrought woollen broad cloth above one yard in length, and half a quarter in breadth; or half cloth, above half a yard in length, and half a quarter in breadth, &c. on pain of forfeiting the ſame, half to the overſeer or informer, and half to the poor. 43 Eliz. c. 10. If any cloth remaining on the tenters be ſtolen in the night, and the ſame is found on any perſon, on a juſtice's warrant to ſearch, ſuch offender ſhall forfeit to the owner treble value, leviable by diſtreſs and ſale, or be committed to gaol for three months, or till the fine be paid; but for a ſecond offence he ſhall ſuffer ſix months impriſonment; and for the third offence, he ſhall be guilty of felony, and tranſported for ſeven years. 15 Geo. II. c. 27. No woollen cloth ſhall be exported, till it be barbed, rowed, and ſhorn, on pain of forfeiting the ſame, half to the king, and half to him that will ſue. 5 Hen. VII. c. 11. No perſon ſhall uſe iron cards, or pickards, in rowing of cloth, on pain of forfeiting the cards, and 20*s.*; nor ſhall any perſon put any flocks, chalk, flour, or ſtarch, or other deceivable thing on cloth, on pain of 40*s.* 3 and 4 Edw. VI. c. 2. No cloth ſhall be rowed or raiſed with oil, greaſe, or any liquid, except on the edge of the ſhears with ſemet or oils, on pain of 13*s.* 4*d.*; and there ſhall be no cutting of wool from the backſides of cloth, except with ſhears, in pain alſo of 13*s.* 4*d.*; nor ſhall any liquid be uſed on the ſide of the cloth, to make it look better than the inſide; nor ſhall the ſides be raiſed, fulled, rowed, or ſhorn, better than the middle, on the like penalty. 4 Jac. c. 2. No perſon ſhall preſs cloth with a hot preſs, on pain of forfeiting the ſame or value. 5 and 6 Edw. VI. c. 6. And preſſing of cloth with hot boards ſhall be puniſhed with like forfeiture. 21 Jac. c. 18. With regard to mixed or medley broad cloth, it is provided by 10 Ann. c. 16. and 1 Geo. ſt. 2. c. 15. that the fulling miller ſhall take an oath before a neighbouring juſtice, to duly meaſure ſuch cloth fulled at his mill, when fulled and wet, affix to it a ſeal of lead, marked with a crown, and ſtamped with his name; together with the length and breadth of the cloth; for which he ſhall have one penny, and enter in a book the marks, ſort, number, length, and breadth of it; under a penalty of 20*l.* on conviction in 40 days, before one juſtice, or on oath of one witneſs, leviable by diſtreſs; or, in want of diſtreſs, commitment to the gaol or houſe of correction for three months. Counterfeiting, defacing, or altering the ſeal incur the ſame forfeiture of 20*l.* Selling cloth before it is ſo ſealed ſubjects to a forfeiture of one-ſixth part of the cloth. If the buyer is not ſatisfied with the meaſure, he may have it again meaſured in the water, within eight days after delivery; the buyer and ſeller chooſing each a meaſurer; and if it does not contain the quantity ſpecified in the ſeal, the owner or ſeller ſhall forfeit one ſixth part of the value. By 13 Geo. c. 23. inſpectors of mills and tenters ſhall be appointed by juſtices at Eaſter ſeſſions, in the counties of Glouceſter, Wilts, and Somerſet, for examining and ſealing cloths; and millmen ſending home cloths before inſpection ſhall forfeit 40*s.* perſons refuſing entrance to the inſpector ſhall forfeit 10*l.*; and the inſpector acting againſt his oath, ſhall forfeit 20*l.* Such inſpectors ſhall be paid 2*d.* for each cloth by the clothiers; the Yorkſhire manufacture is ſubject to peculiar regulations by 11 Geo. II. c. 28. 5 Geo. III. c. 51. 6 Geo. III. c. 23. No foreign woollen cloth ſhall be imported, on pain of forfeiture, and further puniſhment at the king's will. 11 Edw. III. c. 3. 4 Edw. IV. c. 1. Woollen manufactures ſhall be exported cuſtom free. 11 and 12 W. c. 20. By 12 Geo. c. 34. if any weavers of cloth enter into any combination for advancing their wages, or leſſening their uſual hours of work, or depart before the end of their terms agreed, return any work unfiniſhed, &c. they ſhall be convicted by two juſtices of peace to the houſe of correction for three months; and clothiers are to pay their work-people their full wages agreed upon in money, under the penalty of 10*l.* &c.

CLOTNIZA, in *Geography*, a town of Poland, in the palatinate of Lublin; 15 miles W.S.W. of Lublin.

CLOUD, a viſible aggregate of minute drops of water ſuſpended in the atmoſphere.

The word is probably derived from the Anglo-Saxon Lehlod, *covered, hidden*, the face of heaven being ſo in thoſe parts where clouds appear. The ſame aggregate, which in this ſituation is called cloud, obtains the name of miſt, when ſeen to ariſe from the earth or waters; and fog, when it envelopes and covers the obſerver. Yet the two latter, viewed from a greater diſtance or elevation, preſent all the appearances of clouds; while theſe, in their turn, become miſts and fogs, in proportion as we approach and penetrate them. It may be proper, therefore, for the ſake of preciſion, that the term cloud, in philoſophical language, ſhould be made a general one, comprehending all ſuch aggregates, however ſituated.

It is concluded, from numerous obſervations, that the particles of which a cloud conſiſts are always more or leſs electrified. The hypotheſis, which aſſumes the exiſtence of veſicular vapour, and makes the particles of clouds to be hollow ſpheres, which unite and deſcend in rain when ruptured, however ſanctioned by the authority of ſeveral eminent philoſophers, does not ſeem neceſſary to the ſcience of meteorology in its preſent ſtate; it being evident that the buoyancy of the particles is not more perfect than it ought to be, if we regard them as mere drops of water. In fact they always deſcend, and the water is elevated again only by being converted into inviſible vapour.

Clouds, *Natural Hiſtory of*. Since the general introduction of accurate inſtruments for determining the changes of denſity, temperature, humidity, and electricity, which continually occur in the atmoſphere, our knowledge of its conſtitution and properties has been conſiderably advanced. It is nevertheleſs true that the philoſopher of the preſent day is not more weather-wiſe than his predeceſſors in ancient times. He is ſtill obliged to yield the palm in the ſcience of prognoſtics to the ſhepherd, the ploughman, or the mariner; who, without troubling his head about the reaſons of things, has learned, by tradition and experience, to connect certain appearances of the ſky with certain approaching changes; of which thoſe appearances are, in fact, a commencement or continuation, diſcoverable while the cauſe is yet at a diſtance. Undoubtedly the union of theſe two kinds of knowledge would beſt deſerve to be entitled the ſcience of meteorology; and it muſt tend, equally with the invention or perfection of philoſophical inſtruments, to the improvement of this ſcience, could we reſtore to its place the ancient and popular branch of it, now too much neglected by philoſophers, which is founded wholly on natural phenomena. If we except the changes of the wind, ſome indications of moiſture and dryneſs, and a few others of leſs importance, the whole of theſe may be traced to one common origin in the product reſulting from the decompoſition of vapour; which remains, during a certain interval, in a ſtate of ſimple diffuſion or ſuſpenſion in the atmoſphere. To give to the extenſive collection of facts, which it is eaſy to make on this ſubject, a communicable and uſeful form; to render that attainable in a ſhort time, which has been hitherto the excluſive treaſure of the adepts of long experience, is the object of the writer of the following ſyſtematic nomenclature and natural hiſtory of clouds.

Clouds are ſuſceptible of various modifications. By this term is intended the ſtructure or manner of aggregation, in which the influence of certain conſtant laws is ſufficiently evident amidſt the infinite leſſer diverſities reſulting from occaſional cauſes.

Hence the principal modifications are as diſtinguiſhable from each other, as a tree from a hill, or the latter from a lake; although clouds, in the ſame modification, compared with each other, have often only the common reſemblances which exiſt among trees, hills, and lakes, taken generally.

There are three ſimple and diſtinct modifications, which are thus named and defined.

1. Cirrus. *Def.* Nubes cirriformis tenuiſſima, quæ undique creſcat.

The Cirrus. A cloud reſembling a lock of hair, or a feather. Parallel flexuous, or diverging fibres, unlimited in the direction of their increaſe.

2. Cumulus. *Def.* Nubes denſa cumulata, ſurſum creſcens.

The Cumulus. A cloud which increaſes from above in denſe, convex, or conical heaps.

3. Stratus. *Def.* Nubes ſtrata, aquæ modo expanſa, deorſum creſcens.

The Stratus. An extended, continuous level ſheet of cloud, increaſing from beneath.

There are two modifications, which appear to be of an intermediate nature; theſe are:

4. Cirro-cumulus. *Def.* Nubeculæ ſubrotundæ connexæ vel ordinatè poſitæ.

The Cirro-Cumulus. A connected ſyſtem of ſmall roundiſh clouds, placed in cloſe order, or contact.

5. Cirro-ſtratus. *Def.* Nubes extenuata, ſub-concava vel undulata. Nubeculæ hujuſmodi appoſitæ.

The Cirro-ſtratus. A horizontal or ſlightly inclined ſheet, attenuated at its circumference, concave downward, or undulated. Groups or patches having theſe characters.

Laſtly, there are two modifications, which exhibit a compound ſtructure, *viz.*

6. Cumulo-ſtratus. *Def.* Nubes denſa, quæ baſi cumuli ſtructuram patentem cirro-ſtrati, vel cirro-cumuli ſuperdat.

The Cumulo-ſtratus. A cloud in which the ſtructure of the cumulus is mixed with that of the cirro-ſtratus, or cirro-cumulus. The cumulus flattened at top, and overhanging its baſe.

7. Nimbus. *Def.* Nubes denſa, ſupra patens et cirriformis, infra in pluviam abiens.

The Nimbus. A denſe cloud, ſpreading out into a crown of cirrus, and paſſing beneath into a ſhower.

Of the Cirrus.

This is always the leaſt denſe, and commonly the moſt elevated modification. It is ſometimes ſpread horizontally through a vaſt extent of atmoſphere; the whole breadth of the ſky being inſufficient to ſhew where it terminates. In this caſe, its parallel bars appear, by an optical deception, to converge in oppoſite points of the horizon. At others, it is exhibited in unconnected perpendicular bundles, of the moſt minute ſize. Between theſe extremes, it may be traced in every degree of extent and inclination to the horizon. In a ſerene ſky the cirrus is firſt indicated by a few threads, pencilled in white, on the azure ground. Its increaſe takes place in various ways, and may be compared ſometimes to vegetation, more often to cryſtallization. Thus, 1. Parallel threads are added to each other horizontally, and occaſionally other ſtrata of the ſame, croſſing the firſt at right or oblique angles, until a delicate tranſparent veil is formed. 2. Parallel threads are collected into diſtinct groups, lying at various angles with the horizon. 3. Flexuous and diverging

verging fibres are extended from the original ftem, forming the refemblance of crefts of feathers, locks of hair, &c. 4. The firft-formed threads become, as it were, the fupports from whence others obliquely afcend or defcend into the atmofphere. Laftly. A denfe nucleus is fometimes formed, and fhort fibres fhoot out from it in all directions. The great elevation of the cirrus has been afcertained by geometrical obfervations. "The fmall, white ftreaks of condenfed vapour, which appear on the face of the fky, I have found," fays Dalton, "by feveral careful obfervations, to be from three to five miles above the earth's furface."

Viewed from the fummits of the higheft mountains, they appear as diftant as from the plains. A more eafy and not lefs convincing proof of their elevation may be deduced from their continuing to be tinged by the fun's rays in the evening twilight with the more vivid colours of the prifm, while the denfer clouds, having already paffed through the fame gradation, are in the deepeft fhade.

The duration of this cloud varies according to its ftation in the atmofphere; and the prefence or abfence of other clouds; it is long, extending fometimes to thirty-fix hours, when it appears alone, and at its greateft elevation; but fhorter, or even very tranfient, when formed lower, and in the vicinity of the cumulus.

By an inexperienced obferver the cirrus would be pronounced abfolutely motionlefs. On comparifon with a fixed object, however, it is fometimes found to have a confiderable progreffive motion. The propagation of the cirrus, and the variable direction of its flexures, merit attentive obfervation, as being intimately connected with the variations of the wind, although undoubtedly not produced by the mere motion of the air.

The general principles, which the imperfect notice hitherto beftowed on it feems to point out, are the following:

1. Its appearance is a general indication of wind; and it is moft confpicuous and abundant before ftorms.

2. It is often a leeward cloud; or, when a group of cirri appears on the horizon, it feems to invite a current towards it; and the wind very often fhifts into that quarter towards which the points are directed.

3. Horizontal fheets of the cirrus, more particularly thofe which carry ftreamers pointing upward, are among the indications of rain approaching, while the fringe-like depending ones are found to precede fair weather.

Of the Cumulus.

Clouds in this modification are commonly of denfe ftructure. They are formed in the lower atmofphere; and move with the wind, or more properly with that current which flows next the earth. The phenomena of the cumulus are ufually thefe: In the latter part of a clear morning, a fmall irregular fpot appears fuddenly at a moderate elevation. This is the *nucleus*, or commencement of the cloud, the upper part of which foon becomes convex and well defined, while the lower continues irregularly plane. On the convex furface the increafe vifibly takes place, one heap or protuberance fucceeding another, and again lofing itfelf in a fubfequent one, until a pile of cloud of an irregular hemifpherical form is raifed; which floats along, prefenting its apex to the zenith, while the bafe, or rather the lower furface of the bafelefs fabric, continues parallel to the horizon.

When thefe clouds are of confiderable magnitude, they remain at proportionately great diftances. When fmaller, they croud the fky by a nearer approach to each other. In each cafe the bafes range in the fame plane; and the increafe of each keeps pace with that of its neighbour, the intervening fpace remaining clear.

The cumulus often arrives at its greateft magnitude early in the afternoon, when the temperature of the day is at its maximum. As the fun declines, it gradually decreafes, retaining its character till towards fun-fet, when it is more or lefs haftily broken up, and evaporates, leaving the fky clear, as in the early part of the morning. Its tints are often vivid, and pafs through the moft pleafing gradation during this laft hour of its exiftence.

The preceding phenomena form the hiftory of the pure cumulus, as it may be termed, when no other modification appears along with it. They are both the accompaniments and prognoftics of the faireft weather.

Of the Stratus.

The ftratus has a moderate degree of denfity. It is the loweft of the modifications, being formed in contact with the earth or water. It comprehends thofe level creeping mifts, which, in calm evenings, fpread like an inundation from the valleys, lakes, and rivers, to the higher ground.

Unlike the cumulus, which belongs to the day, and rarely furvives the fetting fun, this cloud accompanies the fhades of night, and commonly vanifhes before the afcending luminary. The evaporation commences from below. At the moment of the feparation of the ftratus from the earth, its character is changed, and it puts on the appearance of the nafcent cumulus.

The nocturnal vifits of the ftratus have been always held a prefage of fair weather. Thus Virgil:

"At nebulæ magis ima petunt campoque recumbunt."

Then mifts the hills forfake and fhroud the plain.

The meteorological axioms of this great poet were probably felected from the popular ones of his age, as confirmed by his own experience. Hence they ever agree with that of his readers. There are few days in the whole year more calm and ferene than thofe whofe morning breaks out through the ftratus. They are the halcyon-days of our autumns; an interval of repofe beween the equinoctial gales and the ftorms of winter.

Of the Cirro-cumulus.

The intermediate nature of this cloud may be afcertained by tracing its origin, as well as inferred from its ftructure. The cirrus, in its flow defcent through the air, may be feen to pafs into this and the next modification; although its previous appearance does not feem abfolutely neceffary to the production of either.

Moft of our readers will recollect the appearance of the icy efflorefcences on the panes of windows, gradually melting into an affemblage of drops, which adhere to the glafs, retaining fomewhat of the fame figure, deprived of its right lines and angles. Such is the change of form which the cirrus undergoes, in paffing to the ftate of the cirro-cumulus. And, as the water on the windows is occafionally converted again into fpiculæ of ice, fo thefe fmall rounded maffes fometimes fuddenly refume the forms of the cirrus. In the oblique denfer tufts of the latter, the change to the fpheroidal form often begins at one extremity, and proceeds gradually to the other, during which the cloud refembles a ball of flax, with an end left unwound and flying-out. All the cirri in the fame group, and frequently all thofe in view, obferve the fame law in thefe changes.

The cirro-cumulus forms a very beautiful fky. Numerous diftinct beds are fometimes feen floating at different altitudes, which appear to confift of fmaller and ftill fmaller clouds,

clouds, as the eye traces them into the blue expanse. It is most frequent in summer; is the natural harbinger of increased temperature; and, consequently, one of the best indications of fair weather, when permanent or frequently repeated. A more transient display of it is, however, frequent in the intervals of warm showers, and in winter. There are also certain forms of it, more deep and dense than ordinary, and arranged on a curved base, which enter into the peculiar features of thunder-storms.

It is usually found to accord with a rising barometer.

Of the Cirro-stratus.

This is a multiform cloud, and can only be detected in its various appearances by an attention to its distinctive characters. It is always an attenuated sheet, or patch, floating on the air, in a position nearly or quite horizontal. As we have compared the cirrus to dry flax, we may here consider it as drenched in water, and having its spreading fibres reduced to a closer and recumbent form. Viewed over head, it is remarkable for its uniform hazy continuity, and in the horizon for its great appearance of density, the consequence of its being seen edgewise. In this situation, also, it sometimes cuts the sun's or moon's disk across with a dark line; of which Virgil,

> " Ille ubi nascentem maculis variaverit ortum
> Conditus in nubem, medioque refugerit orbe,
> Suspecti tibi sint imbres: namque urget ab alto
> Arboribusque, satisque notus, pecorique sinister."
> Georgic. lib. i.
>
> Or should his rising orb distorted shine
> Thro' spots, or fast behind a cloud's dark line
> Retire eclipsed; then let the swain prepare
> For rainy torrents; a tempestuous air,
> Swift from the southern deep, comes fraught with ill,
> The corn and fruits to waste, the flocks to chill.

The cirro-stratus is the natural indication of depression of temperature, wind and rain. In order to make a proper use of it in this respect, it is necessary to attend to the time of its appearance, to its continuance, and its accompaniments. This cloud sometimes alternates with the cirro-cumulus, either at different intervals of the day, or in the same sky, or even in the same stratum, which may consequently be seen successively in each modification, and at intervals, partly in one, partly in the other. In this case the prognostic is doubtful, and regard is to be had to that which ultimately prevails.

Again, there is a transient appearance of the cirro-stratus, which often accompanies the production of dew in the evening, and denotes an atmosphere but lightly surcharged with vapour. Not so when it appears earlier in the day, or at sun-rise (according to the preceding quotation), and attended with the rudiments of the cumulus. In general, the weather may be suspected of a strong tendency to wind and rain, as often as the sky is both hazy, and deformed with numerous small patches of cloud, in which the extenuated character predominates; and these appearances, together with an abundance of cirro-cumulus, indicate thunder. Before storms of wind, there is in particular a feature of cirro-stratus, often very slightly expressed, and in one quarter only, which resembles the architectural cyma.

But the most formidable appearance of the cirro-stratus, is that of extensive sheets, descending from the highest regions of the atmosphere, and scarcely discernible for a time, but by the prismatic colours which they assume in the vicinity of the sun's or moon's place. These are the skreens on which are described the immense circles of halos, forming, by their occasional intersections, parhelia, and paraselenia, mock suns and moons, which sometimes vie in splendour with the luminaries themselves. It is easy for those who are acquainted with the principles of optics, to conceive how these intersecting circles are produced by light passing through sheets of cloud placed at different heights and angles.

Consistent with this is the prognostic of foul weather commonly deduced from the appearance of the halo. After a solar halo in spring, or the early part of summer, a series of wet and cold weather may be expected, although it should not commence for some days; during which, nevertheless, the same state of the atmosphere subsists, as is often manifest from the repetition of the halo. Those which surround the moon in clear nights, indicate rain or snow, according to the season of the year.

In mountainous and even hilly countries, the cirro-stratus is frequently seen adhering to the more elevated points of land. In winter it also visits the plains, in the form of a very wet and durable mist, the drops of which are nevertheless too small to be visible, and which, unlike the stratus, is more dense on rising grounds than in the valleys.

The cirro-stratus usually accords with a sinking state of the barometer.

Of the Cumulo-stratus.

The formation of the cirro-cumulus, or cirro-stratus, by condensed vapour, descending from the higher atmosphere, does not prevent the cumulus from being produced out of the water, which, in the mean time, evaporates, from the earth and ascends to the middle region. In this case, the two modifications after a while come into contact, and present to the attentive observer a succession of curious appearances.

While the cumulus is rapidly increasing upward, a delicate fleece, of a structure visibly different, sometimes attaches itself to its summit; where it reposes as on a mountain. This fleece is a cirro-stratus; and the materials of which it is formed are brought by a superior current overtaking or meeting the cumulus. Frequently, the cumulus in its increase breaks through the cirro-stratus, and appears again above it, but with a visible change in the aggregation, which now becomes rocky, perpendicular, and, finally, overhanging. If the cirro-stratus should itself increase too fast to be swallowed up by the cumulus, the latter after a while extends its protuberances laterally, and attaches itself by them to the superior mass of cloud.

When the cirro-cumulus, in like manner, occupies the superior place, a cumulus rising beneath it is susceptible of the same union by mutual attraction; the result of which, as in the former case, is a large, lofty, and dense cloud, which often subsists through the day; and in the evening undergoes the usual evaporation.

It is not, however, absolutely necessary to the production of this cloud, that either of the superior modifications should be previously formed. In a favourable state of the atmosphere, the cumulus itself, after having arrived at a certain magnitude, suddenly begins to over-grow its base, and produces a cloud, which, in regard both to its form and its rapid growth, may be compared to a mushroom.

The cumulo-stratus usually prevails in the completely overcast sky. In this it presents appearances not easy to be described, but which may be classed by a due attention to the theory of this cloud. At present it is intended to comprehend under it every mode of union between different strata, which is not productive of rain. Future investiga-

tion

tion may point out diſtinctions, which at preſent we are not prepared to make.

This modification is moſt frequent during a mean elevation of the barometer, or that which is denominated *changeable*, when the wind blows from the weſt, with occaſional deviations towards the north and ſouth. In reſpect to temperature, it has a wide range, and may uſher in a fall of ſnow, as well as a thunder-ſtorm. Of the latter, indeed, it is among the regular harbingers, but with peculiar appearances. During the ſuffocating calm which prevails before the firſt diſcharge of the atmoſpheric electricity, it may be ſeen in different points of the horizon, rapidly ſwelling to a ſtupendous magnitude, moſt curiouſly wreathed and curled, "fretted and emboſſed" in its ſubſtance, and flanked at different heights by the delicate opake ſtreaks of the cirro-ſtratus. The whole preſents a ſpectacle of peculiar magnificence, in contemplating which, one may imagine an inviſible agent collecting in this immenſe laboratory the energies of the ſtorm, and arranging innumerable batteries for the ſubſequent exploſions.

It will appear by what we have already ſtated, that the cumulo-ſtratus affords in general a doubtful prognoſtic. When it is formed in the morning, the day often proves fair, though overcaſt; and if the cirro-ſtratus has contributed to its formation, there will probably enſue heavy ſhowers on the ſecond or third day. When it ſubſiſts a long time, the character of its ſuperior ſpreading part may be conſulted, which, if it be decidedly either that of the cirro-ſtratus, or cirro-cumulus, the uſual reſult of their appearance may be expected.

Of the Nimbus.

To have a correct notion of this cloud, the reader has only to take the opportunity of examining a ſhower in profile as it approaches from the horizon. He will ſee the denſe gloom, which experience teaches him to regard as a maſs of deſcending rain, loſing itſelf above in a cloud which commonly ſpreads in one continuous ſheet to a great diſtance all around the ſhower; inſomuch that while the latter is on the horizon at ſeveral miles diſtance, the edge of the cloud has frequently arrived in the zenith. He will perceive that this ſpreading crown of the ſhower advances regularly before it, and that, whether viewed from a diſtance or over-head, it exhibits in a greater or leſs degree the fibrous ſtructure of the cirrus. After the ſhower has paſſed over, he will commonly obſerve the ſame appearances in the part of the cloud which follows it; and in ſqually weather he will ſometimes be able to repeat theſe obſervations on many different ſhowers appearing ſucceſſively; or at the ſame time, in different quarters. The term *nimbus* is intended ſtrictly to denote no more than this inverted cone of cloud, from which a ſudden or denſe local ſhower, whether of rain, ſnow, or hail, for the difference is not eſſential in either caſe, is ſeen to deſcend. As it riſes to a great height in the atmoſphere, it may be ſeen from a diſtance of many miles; and ſo conſtant is the reſult of a ſhower arriving with it, that though, in a few inſtances, perhaps from the ſmall quantity of the rain, we have not been able to diſcover the uſual obſcurity beneath it, while at a diſtance, we believe it may be laid down as a general rule, on as good grounds as in moſt other caſes, that rain, ſnow, or hail, is falling on the tract over which it is ſpread.

> "Qualis ubi ad terras abrupto ſidere *nimbus*
> It mare per medium, miſeris heu preſcia longé
> Horreſcunt corda agricolis." Virgil.

> So while far off at ſea the ſtorm-cloud lowers,
> And on the darken'd wave its fury pours,
> Mid crops unreap'd the hapleſs peaſants ſtand,
> And ſhuddering view its rapid courſe to land.

There is a great difference, at different times, in the proportion which the inverted cone of cloud bears to the column of rain, &c. in which it terminates; and in a very turbid and moiſt atmoſphere, the character of the upper part often approaches more nearly to the cirro-ſtratus than the cirrus. The more perfectly diſtinct and local the ſhower, and the clearer the reſt of the air from other clouds, the more perfect the crown of cirrus, which, indeed, ſometimes aſſumes an almoſt geometrical preciſion in its form and internal ſtructure; the threads of the cirrus tending from all ſides directly towards the top of the column.

The pure nimbus commonly moves with the wind, and from the rapidity of its paſſage affords but little to the rain-gauge. But it often happens, that it is formed in the midſt of cumuli which have already arrived at a great ſize. In this caſe the latter may be ſeen to enter ſucceſſively into the focus at the top of the column, from whence they never emerge; being viſibly converted to the purpoſe of ſupplying materials for the irrigation, which thus becomes more abundant; and the ſhower is alſo occaſionally thus propagated in a direction oppoſite to the wind.

The nimbus, moreover, does not always originate in a cirrus. The cumulus, and more often the cumulo-ſtratus, may be ſeen to expand at their ſummit into a cirroſe ſheet, while the lower part is reſolved into rain. On the contrary, the rain ſuddenly ceaſing, and the nimbus remaining entire, the ſharp extremities of the crown often retire into it; the ſides aſſume the ſwelling folds, and the character is exchanged for that of cumulo-ſtratus. When the ſhower has expended itſelf, and the ſheet breaks, the ſuperior portions uſually turn to the cirro-cumulus or cirro-ſtratus, and the lower to the cumulus. When a total evaporation of the remaining cloud follows a ſhower, it is a very favourable prognoſtic. A nimbus is frequently accompanied by a cirro-ſtratus or two lying near it, and on a level with the denſeſt part of the cloud. The nimbus of thunder-ſtorms has many of theſe, as before obſerved of the cumulo-ſtratus, arranged at different heights; which, with the groteſque form of each cloud, and the hazy ſtate of the medium, are ſufficiently characteriſtic of the high electric ſtate of the air at ſuch times, and want only an attentive peruſal (in nature) to enable the obſerver to aſcertain it on future occaſions. It appears that the cumulo-ſtratus paſſes to the nimbus by a ſudden change in its electricity: for in tracing the progreſs of a thunder-ſtorm, through a long range of theſe clouds in the horizon, we have been ſatisfied, that the clouds, which had ceaſed to afford exploſive diſcharges, had undergone this change in their ſuperior part, and were pouring down rain; while others, among which the lightning ſtill played, or which were ſituated beyond it, retained their ſwelling and rounded forms ſome time longer.

Of the Origin, Suſpenſion, and Deſtruction of Clouds.

Theſe aggregates conſiſt of water, raiſed by evaporation, and become viſible by condenſation in the atmoſphere. Reſpecting evaporation, and the ſtate in which vapour ſubſiſts, there has been much diverſity of opinion: and, of the ſeveral theories propoſed, there is not one comprehenſive enough to merit excluſive adoption. A number of general principles, however, have been eſtabliſhed; which we ſhall employ, with the aid of thoſe of electricity (hitherto not enough confidered in its filent and gradual effects), to explain, though in an imperfect manner, the principal phenomena of clouds.

Evaporation confifts in the union of water with caloric, and the efcape of the compound as an invifible fluid, which we fhall exclufively denominate *vapour*.

The folvent action of the air, to which this effect has been attributed by chemical philofophers in general, has been proved by comparative experiments on the force of vapour in air, and with air excluded, to have no perceptible fhare in it. The laws which govern the natural procefs, (for thefe alone here intereft us) may be thus briefly ftated. The force by which water is converted into vapour is directly as its temperature, other things being equal: but this force has to overcome an oppofing one, of the fame nature, inherent in the vapour which already exifts in the atmofphere. For fuch vapour, by its elaftic property, tends to exclude from the fpace it occupies every additional portion; and confequently to prevent the efcape from the water of new vapour. Hence the temperatures being equal, the quantity of vapour produced will be lefs, the greater the quantity already diffufed in the air.

But though the *chemical* action of air is imperceptible, its *mechanical* effect is great. A moving atmofphere may double or triple the rate of evaporation, according to its velocity. For not only is the furface, from whence only the vapour efcapes, thus enlarged and changed; but the nafcent vapour itfelf, which would otherwife hover a while upon it, to the obftruction of the procefs, is immediately brufhed away and diffufed.

By applying thefe principles, we may explain to ourfelves various natural phenomena: as for inftance; why the wind, after rain, becomes colder than even the rain which fell; being robbed of its caloric by the evaporation of the floating and depofited water, with which it is in contact: why fnow fometimes totally difappears without melting, and the furface of ice becomes fenfibly wafted and channelled; for thefe are warm, compared with the dry and frofty air which blows at fuch times, and confequently evaporate freely. In what manner, again, a ftrong wefterly wind in fummer or autumn brings up clouds, which on its ceffation defcend in rain: for it promotes evaporation by its mechanical effect, and the vapour efcapes into an atmofphere already too moift to carry it off to any great diftance. This will be evident by recurring to the principle before ftated, that the vapour efcapes by the force of the temperature of the water out of which it is formed; and, confequently, into a colder atmofphere it will ftill efcape, though continually decompofed thereby.

Vapour is decompofed by air, in confequence of the fuperior affinity of the latter to caloric. This happens in two ways. 1. When vapour efcapes or is propelled into air colder than itfelf; the refult being a local denfe cloud. 2. When a mixture of air and vapour is cooled; in which cafe there enfues a general turbidnefs, which we fhall exclufively denominate *haze*. It is occafioned by minute floating particles of water; the caloric which, united to thefe, formed tranfparent vapour, having paffed into the air.

Out of this haze clouds may be afterwards formed, by fimple aggregation, or by electrical attraction. It abounds in the atmofphere during moft part of the year, occupying fometimes the higher, fometimes the lower, part thereof. The quantity in which it exifts may be judged of, at fome periods, by the appearance of diftant objects feen horizontally: at others, by the degree of intenfity of the blue colour of the fky, which becomes paler by it, if indeed the bluenefs is not wholly due to this part of the medium.

Of the Nature of the Stratus.

This cloud is an example of the decompofition of vapour thrown into air of a lower temperature. The earth or water on which it repofes is always warmer than the cloud, as is alfo the clear air above. Thus, in a ftratus, formed over a field with ponds, the temperature of the earth juft below the turf was 57°; of the water, 59°; of the air, at an elevation of thirty feet, 55°; while that of the cloud, at four feet from the ground, was 49.5°. Hence this cloud preferves a level furface; and hence it uniformly vanifhes, or begins to be driven upward, as foon as its temperature becomes equal to that of the earth. It is confequently due to the decompofition (in a fmall portion of the atmofphere) of the vapour which the earth and water continue to emit, after funfet, by the force of a temperature previoufly acquired. But the change in the lower air, which gives occafion to this local decompofition, is not fo eafily to be explained: for it appears that very often, in the evening of a clear day, the decreafe of temperature in the atmofphere takes place in the fame order in which the increafe did in the morning: *viz.* beginning from the furface of the earth and proceeding upward. If the air never became colder, on thefe occafions, than the contiguous foil, the effect might very well be afcribed to the abforption of a quantity of caloric by the latter. But we fee that, in the prefent inftance, it became colder by feven degrees, though vapour was ftill decompofing: and this in a perfect calm, which, in a great degree, forbids another fuppofition, of the exchange of a quantity of heated air below, for as much cold air from the higher atmofphere; otherwife this would feem a fufficient account of the matter.

The electric charge of the ftratus, which is always pofitive, and fometimes highly fo, notwithftanding the contact of its lower furface with the earth, feems to prove that a cloud is not even fo good a conductor as has been fuppofed, and that the fluid, in certain cafes, may be very gradually tranfmitted through it. Pofitive electricity being that proper to the atmofphere in fair weather, we fhould naturally expect to find it in this cloud.

It might be worth while to examine the air above, with a view to difcover whether there exifts in the latter a negative counter-charge. It will appear, from a confideration of the principles before ftated, why this cloud is almoft peculiar to the autumn. The gradual decline of the fun, at this feafon, keeps the atmofphere conftantly furcharged with vapour, which is ultimately difpofed of in rain; and hence follow gales of wind. The ftratus, therefore, though an immediate indication and accompaniment of fair weather, affords an unfavourable prognoftic in the early part of fummer; as it fhows that a tendency has already begun to extenfive precipitation, at a time when the ufual predominant feature is increafing drynefs.

Of the Nature of the Cumulus.

The heating effect of the fun's rays on the atmofphere is greateft near the furface of the earth, and diminifhes gradually in afcending. The diminution proceeds in fair weather at the rate of about one degree for each hundred yards, as appears by obfervations with the thermometer on ftations of known difference in altitude.

This inequality appears to give rife to the cumulus, on the fame principles as thofe of the ftratus, but the effects are more complicated. Vapour is generated, as before, at the furface of the earth, but it is thrown into an atmofphere heated by the fun. Here it maintains its elaftic ftate, and, in proportion to the fupply from below, the whole quantity exifting in the atmofphere is compelled to rife. In doing this, it changes its climate, and arrives among air of a lower temperature, where a portion is continually decompofed, filling the middle region with haze. Of this, fmall aggregates begin to be formed, the increafe of which is at firft determined by no particular law. But the aggregate is not in equilibrium with the air. It tends to fubfide, and in the mean time the increafe of temperature is proceeding upward. Hence the lower part foon finds a pofition in a plane of air fufficiently warm to evaporate it: and as this effect is regulated, in general, by the elevation alone, we fee thefe aggregates affume each a flat bafe, refting as it were on the fame plane, parallel to the earth's furface. The remainder of the cloud fports in all the varieties of the fpheroid, and more rarely of the cone; according to the courfe of the fhowers of minute particles of water, which we may confider (though invifible in their progrefs) as defcending upon it. The vapour generated at the bafe is, probably, in part condenfed on the furface of the colder particles of the cloud above. While the fupply from the haze exceeds the wafte by evaporation, the cloud increafes: when the latter has begun to prevail, it may be traced through various ftages of diminution to its final wreck, on finking wholly into the warmer atmofphere. This happens commonly about fun-fet; becaufe the afcending current of vapour, the fource of the phenomenon, then flackens or ceafes; and the lower air parting with its redundant caloric to the higher, we unexpectedly fee the denfe clouds evaporate, at the very time when the chill of the evening is felt below, and the dew falls.

But it does not appear that the caufes we have hitherto enumerated are fully adequate to the phenomenon. The increafe of the cumulus is often more rapid than confifts with the notion of fimple attraction, exercifed between diftant particles of water, in a refifting medium. When a cumulus is thus increafing, the fmall aggregates in its way do not ufually join it, but feem to vanifh before it. Laftly, the cumulus itfelf, however denfe, never defcends in rain. It is difficult to conceive that fo powerful an attraction could exift for many hours, without bringing the particles together into larger and larger drops, until they were too heavy for longer fufpenfion. If we fuppofe, however, that, from the commencement of its aggregation, the cumulus becomes a pofitively electrified mafs, thefe difficulties vanifh. This mafs may electrify negatively, and attract into itfelf, from great diftances, both the difperfed particles of water and thofe which have already united in much fmaller maffes. Its particles muft be mutually repulfive, and cannot come into contact without a change of ftate: the fame may be faid of the refpective clouds in this modification, when they do not differ too much in furface.

Of the Nature of the Cirro-ftratus.

When a portion of the atmofphere, charged with vapour, is brought over a tract of land of lower temperature than itfelf, its caloric is abftracted in fufficient quantity, ufually to occafion a decompofition of fome of the vapour, and a confequent general turbidnefs.

The fweating, as it is improperly called, of walls and pavements in a thaw, and when rain is about to come on, is from this caufe; the vapour being decompofed on their furfaces. The mift which enfues at thefe times obfcures diftant objects, and occafions the trees, againft which it is borne by the wind, to drip plentifully. It is in fact a cirro-ftratus in contact with the earth, and no phenomenon is more familiar to the inhabitants of hilly tracts. The fame general depreffion of temperature may happen in another way, and higher in the atmofphere. When a cold and moift air flows over a warmer vaporous one, it is obvious that the former may be warmed, and become more tranfparent, at the expence of the latter; which, from the fame caufe, muft become turbid. The haze thus produced will not fubfide with the uniform motion of dew, but rather in fheets, becoming more denfe as they defcend, both from the approximation of their particles, and addition from the vapour they meet with. But the cirro-ftratus is far from affuming always the fimple form, to which the mere effects of gravity might be fuppofed to give rife. It exhibits changes, which can only be attributed to the acquifition, or paffage through it, of fuch fmall portions of electricity, as in a humid medium we may conceive a cloud to be fufceptible of. On thefe occafions it tends either to the ftate of cirrus, or that of cirro-cumulus, of which we fhall treat prefently.

The reafon of the prognoftic afforded by the cirro-ftratus will now be evident. It gives us notice of a change in the ftate of the fuperior atmofphere, which we could not otherwife be certain of, until the current, in its courfe of propagation downward, had begun to affect the denfer clouds, thrown up by the fuperficial evaporation. It is not very uncommon to fee the cirro-ftratus evidently brought by a wind, moving in a different direction from that wherein the cumuli are immerfed on which it fettles. In this cafe the latter are fpeedily arrefted by it, and affume the new courfe, or defcend in rain, by a change of their electricity.

Of the Nature of the Cirro-cumulus.

Let us now reverfe the former cafe, and confider the upper current as both vaporized, and warmer than the air below.

It is probable that the upper is then cooled by that part of the lower which is next to it, though very flowly, from the difficult tranfmiffion of caloric downward. The decompofition of the vapour in the upper current by this means may give origin to the cirro-cumulus; and the peculiar aggregation of this cloud, as diftinguifhable from that of the cirro-ftratus, may be the refult of its acquiring electricity in its defcent in a much greater degree. Such, at leaft, is the inference we may deduce from its abundance before thunder-ftorms; when it is occafionally feen to arrive with the wind in extenfive flocks or ftrata, moving with unequal velocity, and by confequence overtaking each other, until they form a denfe ftationary mafs.

This explanation of the origin of the cirro-cumulus is principally deduced from an obfervation, which we have now fo often repeated, as to regard it as a meteorological axiom; *that the temperature of the day following, exceeds that of the day on which it appears.* Hence, when it continues to recur daily, the weather ftill grows warmer, until a thunder-ftorm, in fome quarter of the heated tract, puts a period to the infulation of the clouds.

Of the Nature of the Cumulo-ftratus.

In attempting to affign caufes to phenomena fo complicated, as thofe which this modification prefents, we may be in danger of admitting a greater number than are really neceffary. It is apparent, however, that in the ftate of things moft favourable to the production of the cumulo-ftratus, there exifts a precipitation, independent of that which gives rife to the cumulus, and fituated in a higher region. As this precipitation affords fometimes the cirro-cumulus, at others the cirro-ftratus, we need not affign to it any other caufe than the one already mentioned, *viz.* a fuperior vaporized current of air. It is not inconfiftent with the

the principles we have laid down refpecting the cumulus, that this cloud fhould alfo be produced at the fame time; it being requifite only that there exift a fufficient action of the fun on the earth's furface, or a fufficient temperature derived therefrom. The inofculation of thefe two orders of cloud, the fingular union which follows, and the eftablifhment of a new centre of attraction, towards which the whole future increafe tends, is the prominent feature in this modification, and the chief fact which remains to be accounted for. As this effect is not conftant and uniform, it cannot be afcribed to gravity alone. Reafoning from analogy, rather than from direct experiment, which it is not eafy here to apply, we may attribute it to a difference in the electric charge of the refpective clouds; which difference, though fmall, ought to produce the ufual appearances of bodies charged plus and minus; *viz.* mutual approach and contact. This effect however appears to enfue rather with regard to the maffes than to the individual particles.

The effect of the highly vaporized ftate of the higher atmofphere is often difcernible in the cumulus from its earlieft appearance; and it is eafy to determine, at certain times, that this cloud, if it continue long, will pafs to the prefent modification. The effect we mean to point out is the uneven growth of the cloud; numerous fmall maffes attaching themfelves to its furface, and giving it an appearance not unlike the curls of a fleece of wool; particularly when feen beneath the fun, in a fituation where the projecting parts may catch the light. If we admit that the cumulus acts, as well by electrical attraction, as by that of gravity, on the furrounding materials, we may here confider them as arriving by fubfidence in too great plenty to be immediately affimilated; in confequence of which they tend to unite among themfelves. A ftill greater quantity of haze, in the region next above the cumulus, gives rife to the curious phenomenon of the *cloud-capped* cloud; when the cumulus is covered at its fummit with a cirro-ftratus; in the fame manner as, in mountainous tracts, this cloud repofes on an elevated point of land. The caufe is probably alike in each cafe, whether it be a lower temperature on a diminifhed electricity which determines to this particular fpot, the commencement of the aggregation of the cirro-ftratus. We may next confider the cumulo-ftratus perfectly formed, and endeavour to affign a caufe for its occafional long continuance: which, however, exceeds the day of its formation only on the approach of thunder: this cloud, as well as the cumulus, very commonly vanifhing about fun-fet, and re-appearing the next day, for fome time. The two ftrata of the atmofphere, which form the fuperior and inferior boundaries of the cloud, are probably, during this time, in fomewhat different ftates of electricity; the one alfo depofiting water, the other receiving it; the broad furface of the cumulo-ftratus may be regarded as a coating, applied to the upper ftratum; and receiving from it a continual acceffion of charged particles of water, the electricity of which is flowly tranfmitted, through the intermediate portion, down to the bafe of the cloud, which is often fome hundred feet below; and where a continual evaporation counteracts the increafe above. Here, while the mafs continues in this modification, the progrefs of the electricity downwards is arrefted by the dry air: for although the infulated rod is found fometimes to be affected with pofitive, fometimes with negative figns, while the bafe of fuch clouds is over it, this effect is commonly influential; and the rod is not charged, as by the paffage of the nimbus. How the electricity of this cloud is affected by the conftant evaporation of a portion at the bafe remains to be afcertained; and the fame may be faid as to the cumulus.

Of the Nature of the Cirrus.

It was neceffary to defer the confideration of the nature of this cloud, until we had developed, in a confiderable degree, the principles on which our theory proceeds. The reader will have feen that we affume the fact of the flow tranfmiffion of the electric fluid through clouds: which in this, as in a former inftance, we apply rather analogically than by induction; the modification in queftion being ufually fo high in the atmofphere, that the electric ftate of the latter, above and below it, cannot eafily be found by actual experiment. Proceeding, however, on this affumption, we fuppofe that the cirrus refembles in its ftate a lock of hair, or a feather, infulated and charged; or rather, that its arrangements refult from the fame caufe with thofe of the coloured powders, which electricians project on a cake of wax, after having touched it with the knob of a charged phial, and which fall into a variety of configurations on the furface. Thus the cirrus may be formed in the air, out of fuch floating particles of water as are prefent, and may ferve the purpofe of collecting and tranfmitting the electric fluid. It is during the prevalence of variable winds that the cirrus moft abounds; and it is reafonable to conclude, that the portions of air, which at thefe feafons are tranfported from place to place, gliding over or interfecting each other, ufually differ fufficiently in temperature to occafion a flight decompofition of the vapour of one of the currents, and in their electric charge fufficiently to induce a communication by means of the conducting medium fo formed. Again, in the gradual cooling of a perfectly calm plate of air, fituated at a great elevation, and confequently free from the occafional caufes of difturbance which prevail below, it is not improbable that the feparation of the caloric from the vapour, and the collection of the electrifed water from the air, may go on together, by a procefs fimilar to the cryftallization of falts, in which much caloric is liberated into the medium. This opinion at leaft feems to be advanced by Kirwan, in his "Effay on the Variations of the Atmofphere," and we may confider the vegetating cirrus as the proper example of it.

Another conjecture might yet be ftarted as to the cirrus. It might be regarded as a cloud wholly formed of minute fpiculæ of ice; fince the air, at a certain elevation, is fufficiently cold throughout the year for this effect. But if it fhould be found that the particles of clouds are fufceptible of a rectilinear arrangement in any cafe at a temperature exceeding 32°, there would be no neceffity for this fuppofition.

If the appearances of the cirrus are as frequent and various at fea as on land, it cannot be doubted that intelligent mariners would find their account in keeping a regifter of them, as connected with the changes of wind, &c. making due allowance for the change of ftation in different obfervations when under fail.

The buoyancy of the cirrus feems to be moft perfect during its firft increafe. It always follows, at length, the common courfe of gravity, and the change to the cirro-cumulus, or cirro-ftratus, which certainly depends on the ftate of the medium it falls into, may be afcribed to the retention or lofs of the electricity.

Of the Nature of the Nimbus.

This phenomenon may be thought to be improperly denominated a modification of cloud, fince it confifts ufually of a column of defcending rain, fnow, or hail, feen in connection with the cloud affording it. As the concluding link in the chain of atmofpherical precipitation, it feems, neverthelefs, moft advantageoufly placed here; and its hiftory,

tory, though far from including all that we may obferve, and could wifh to have explained, on the fubject of rain, is more decidedly illuftrative of the nature of clouds in general than that of any other modification. Moreover, it is fometimes obferved to be formed before the rain begins, which affords fufficient ground for confidering it as a diftinct modification of cloud. We owe to the bold and penetrating conjecture of Franklin, on the identity of lightning and the electric fpark, the invention of a method of inveftigating the electricity of clouds; which, in the hands of experimentalifts, has fince brought out a mafs of facts abundantly fufficient to eftablifh that propofition; and which alfo throws confiderable light on the theory of rain, and other depofitions from the atmofphere. By this method the ftructure of the nimbus may at any time, when it paffes over us, be demonftrated to be that of a natural conductor, by which the pofitive charge of the higher atmofphere is brought down to the earth. For this purpofe, there is provided a rod of iron, or other metal, well infulated on a pillar of varnifhed glafs, the latter being defended from rain by an inverted funnel, foldered or cemented to the part of the rod next above it. The rod fhould be furnifhed with feveral points of wire, a few inches long; and it need not be an elevated one for this purpofe, provided the extremity is clear of other objects capable of drawing off the fluid. The charge is afcertained by pith balls, of a larger or fmaller diameter, to fuit the occafion, fufpended by flaxen threads, on a wire fixed into the lower part of the rod, and terminating in a ball. Near the latter, it is proper to have another ball fixed on a ftout wire, paffing into the ground, to which the fluid, when abundant, may efcape in fparks. This inftrument exhibits a charge of the fame kind with that of the air in which it is immerfed; or, in cafe of rain, &c. the charge of the latter, as compared with that of the air. We will give, in the firft place, the appearances which we have recently obferved during the paffage over the rod of a nimbus of the moft fimple ftructure, having neither a cumulus nor a cirro-ftratus attached to it; which moved along with the lower current through the clear atmofphere, and difcharged a fhower of large opaque hail, the air below being very dry. During the approach of the cloud from the north-eaft, the pith-balls remained clofe until the fpreading crown, which characterifes this modification, had arrived in the zenith. At this time, and while the fhower itfelf was ftill three or four miles diftant, they opened negative. As the cloud came nearer, their divergence increafed until it amounted to full two inches, at which time fparks of confiderable ftrength might be drawn from the rod. After this the negative charge gradually went off, and the balls touched again. In a few moments the edge of the fhower, mixed with a few drops of rain, arrived at the conductor, and the balls inftantly opened pofitive, the charge gradually increafing until fparks were emitted more freely than before. This charge continued during the paffage of the hail, and went off gradually as foon as it was clear of the inftrument. After having clofed, the balls opened again negative, and this charge increafed to a confiderable intenfity, as the fhower receded towards the fouth and fouth-weft, after which it gradually went off: the balls clofed, and finally were left flightly pofitive. From thefe facts, the reader, who is converfant in electricity, will deduce the ftructure of the lower part at leaft of the fhower. He will fee that the defcending hail formed a column pofitively electrified. This, which might be fix or feven miles in diameter, was furrounded with a cylinder of negative electricity, probably extending in every direction three miles further, and refulting from the action of the pofitive centre on the dry atmofphere, in which it was moving. Now the amount of the hail, when melted, was confiderably lefs than $\frac{1}{100}$th of an inch in the rain gauge; and could the defcent of the electric fluid, through the whole fpace, have been rendered as obvious to our fenfes as that of the hail, we fhould probably have faid that the fhower confifted of fire more truly than of ice.

The queftion that naturally prefents itfelf is, Whence came this flood of electricity which accompanied the hail? It was not from the circumftance of the water being frozen, fince a hard fhower of rain equally exhibits a charge, but with this remarkable difference, that whereas fnow, fleet, and hail, are always pofitive, rain is found fometimes pofitive, fometimes negative. The reader may confult, on this head, an extenfive collection of facts in Read's Journal of Atmofpherical Electricity. "Phil. Tranf." vol. lxxxii. The probable fources of negative rain will be prefently mentioned; but to return to the queftion of the origin of the pofitive charge; if we attentively confider the ftructure of the nimbus, it is precifely that which, from the known properties of the electric fluid, we fhould propofe for a conductor formed to acquire the latter. If we detach from it the falling column, and extraneous clouds which ufually attend its progrefs, it will be found to confift of a clofe collection of fibres, diverging from the region of the cumulus, (where it appears the rapid union of the particles into drops is accomplifhed,) to a vaft height and extent in the fuperior atmofphere. The conducting-line, therefore, may be confidered as prolonged from the top of the column, to the very extremity of each of thefe fine fibres of cloud, which are often extended, in all directions, as correctly as thofe of a lock of hair infulated on a charged conductor. The intention in this cafe feems to be not fo much the precipitation of water, as that of the electric fluid which keeps it in fufpenfion. This purpofe accomplifhed, (and the reader may conceive how great a difcharge muft be effected by a number of fuch machines acting at once on a fmall tract of country,) the water unites into larger drops through the whole extent of the atmofphere; it fubfides in a continuous fheet, under which the condenfed product of the fuperficial evaporation moves along, in the form denominated *fcud*; and the rain comes down freely and generally, until the atmofphere is difburthened, or until the partial vacuum which is formed brings in a drier air from the northward.

Negative, as well as non-electric rain (which fometimes falls, though ftrong pofitive and negative figns precede or follow it in the clear air) muft neceffarily refult from the action of a central mafs of cloud, in which a ftrong pofitive charge exifts, on the clouds of lefs extent which fall in its way; and it is to be confidered alfo, that rain, at the elevation in which it is formed, may be perfectly non-electric, (*i. e.* it may refult from the union of clouds differing in electricity, and hence uniting in rain,) yet at the moment of arriving at the earth, it may differ fo much in its charge from the atmofphere below, the only ftandard of comparifon, as to be ftrongly negative or pofitive with refpect to the latter. But thefe confiderations belong more properly to the fubject of atmofpheric electricity.

We fhall conclude with a brief review of the modifications; afcending from the ftratus, formed by the condenfation of vapour, on its efcape from the furface, to the cumulus, collecting the water arrefted in the fecond ftage of afcent; both probably fubfifting by virtue of a pofitive electricity. From thefe proceeding, through the partially conducting cumulo-ftratus, to the cirro-ftratus and cirro-cumulus; the latter pofitively charged, and confiderably retentive of its charge; the former lefs perfectly infulated, and, perhaps,

conducting

conducting horizontally; we arrive thus at the region, where the cirrus, light, elevated, and extended, obeys every impulse or invitation of that fluid which, while it finds a conductor, ever operates in silence; but which, embodied and insulated in a denser collection of watery atoms, sooner or later bursts its barrier, leaps down in lightning, and glides through the nimbus from its elevated station to the earth. See ELECTRICITY ATMOSPHERICAL, EVAPORATION, RAIN, METEOROLOGY.

CLOUD-BERRY, in *Botany.* See RUBUS *Chamæmorus.*

CLOUD'S-HILL *Lime-works*, near Bredon on Charnwood Forest, in Leicestershire. The lime produced from the rock in this part is often called Barrow-lime, and is in such general repute for water-works, that rail-way branches have been constructed to these works, from two different navigations in opposite directions, *viz.* from the *Ashby-de-la-Zouch* canal, a branch of 6¾ miles, and from the *Leicester* navigation, a branch (including a water-level) of 12 miles in length; while a third rail-way therefrom, to be called the *Bredon* rail-way in another direction, was in contemplation at the time that the *Derby* canal was formed, with which and numerous others it was intended to connect; see our article CANAL.

CLOVE, in *Commerce*, is used for the two and thirtieth part of a weigh of cheese, or barrel of butter, *i. e.* eight pounds avoirdupoise $= \frac{1}{14}$ cwt. $= \frac{1}{15}$ quintal, (120 lb.) $= 9.78$, &c. lb. troy. 9 Hen. VI. cap. 8. A clove of wool weighs 7 pounds, and 2 cloves make a stone $= \frac{1}{4}$ tod $= \frac{1}{16}$ cwt. $= \frac{1}{52}$ sack, $= 8.5069$ lb. troy.

CLOVE *Cinnamon.* See CINNAMON.

CLOVE *islands*, in *Geography.* See MOLUCCA.

CLOVE-*july-flowers*, a species of caryophyllus, greatly recommended as cordials, and given in disorders of the head, palpitations of the heart, and in nervous complaints of all kinds. See DIANTHUS CARYOPHYLLUS.

CLOVE-*Pink*, in *Botany.* See DIANTHUS CARYOPHYLLUS.

CLOVE-*tree.* See CARYOPHYLLUS.

CLOVE-WATER, is prepared of brandy, and cloves bruised therein and distilled.

CLOVER, in *Botany.* See TRIFOLIUM.

CLOVER, in *Agriculture*, is the name of a well known plant of the artificial grass kind, of which three sorts are cultivated in the field; the red clover, the middle clover, or cow red clover, and the white clover. The red clover (*trifolium pratense*) is a biennial perennial plant, which rises to a considerable height, has a long tap root, and flowers from May to September.

It has been remarked by Mr. Bannister, in his "Synopsis of Husbandry," that it is "in some places called broad clover, and is distinguished by a large leaf, and blows, as its name implies, with a red blossom. It delights in a rich earth, and of a stiffish nature, but will prosper well on gravels, sands, or chalks. It probably, however, thrives best in clayey or strong deep loamy soil. And the above author thinks, that the most convenient time for sowing this grass is with the oats in February or March, or among the green wheat in those months; though it is not unfrequently sown with the barley in April; but in this latter case, there is danger of its growing to such a height among the corn, as to occasion the barley to lie so long abroad at harvest that the clover may be withered, and hence great mischief may accrue to the barley, if much rain should fall ere it can be brought into the barn; or the barley may be much lodged, so as to destroy the clover; either of which are inconveniencies that one would wish, he says, to avoid; and for these reasons, clover is rarely sown among barley on good lands; but on thin soils these accidents are less to be apprehended."

But Mr. Young says, "there are several methods of sowing this seed, which is so profitable upon almost every farm, that it must be had if possible. 1st. In the drill husbandry, it may be sown and harrowed in, at the time the barley is sown broadcast; a pair of light harrows at the same time following the drill machine, to cover the clover seed. 2dly. It is sown before the roller, when the barley is four inches high; and 3dly. It is hand or horse hoed in, when the corn receives either of these operations, if the farmer is in the practice of giving them.

"These are the methods most commonly used. But Mr. Ducket, he says, drilled the seed in the same drills as the barley, but that way is very uncommon. Another way he has known, has been that of scarifying the barley stubble in harvest on light soils, and sowing the seed alone then." But "of these methods, the first is, he thinks, the surest for a crop, and the most to be recommended, notwithstanding the admitted evil which sometimes takes place in a wet season, of the clover growing so luxuriantly as to damage the barley. The second succeeds well, if rain follows in due time, and would perhaps generally succeed, if the farmer ventured to harrow it in, which he might safely do. In the third method it often succeeds, but it also often, as he says, fails; nor is it necessary, in many cases, to hoe the barley."

It is further stated, that, "in regard to the quantity of clover which the farmer sows, he has several considerations to govern his determination. In the first place, it is in many situations, and on many farms, as profitable a crop as any other he commonly reaps. On tolerably good land, he may expect, at two mowings, three tons of hay; on good, three and a half, and even four; or, if he applies it to soiling his teams for want of lucern, the produce, in a different way, is equally striking. This produce is also gained at a very cheap rate; cheaper than he gets any other crop. Add to this, that it forms an excellent preparation for either beans or wheat. Still, however, the quantity to be sown will depend in some measure, on his having lucern, saintfoin, or a great plenty of meadow land. If he is deficient in these, it becomes more than useful; it is essential." But, says he, "the unfortunate circumstance which attends clover is, its being extremely apt to fail, in districts where it has been long a common article of cultivation. The land, to use the farmer's term, becomes sick of it. After harvest, he has a fine plant, but by March or April, half, or perhaps more, of it dead. This makes a new course of crop necessary. Instead of its occurring once in four years, in the common Norfolk course, it becomes necessary to sow it only," he says, "in the second round alternately, beans after barley, in one course, and then clover in the next. This has been found to answer. This observation, however, should be made not without observing, that on a farm at Merton in Surry, Mr. Arbuthnot, by means of deeper ploughing than common, and ample manuring, succeeded well with clover every third year in this course: 1. beans; 2. wheat; 3. clover; on land that was said to be sick of it, though sown before only once in four years. He viewed his crops in that new course during three rounds, and never saw finer." Much caution is necessary in repeating it frequently, as various facts in the different surveys of the kingdom fully show.

In respect to the proportion of seed that may be necessary, the same able writer states, that from "ten to twelve pounds an acre is the usual quantity of seed, but that fifteen is better;" and that "as clovers are liable to decline or go off," very early in April, and in some seasons in March, the young clovers should be carefully examined, as a full plant in autumn

autumn often dies away in winter and ſpring; ſo that, by this month, the farmer is in doubt whether he ſhall let it ſtand or plough it up. In this caſe, it is highly adviſable, he thinks, to dibble into all the vacant ſpots ſpring tares, which thus take extremely well, and between clover and tares a very ample crop is produced," and that of a ſort that is of the greateſt utility to the farmer.

But it has been ſtated by Mr. Donaldſon, in his account of the preſent ſtate of huſbandry in Great Britain, that in the northern diſtricts, "the quantity of ſeed allowed to the Engliſh acre, when it is intended to plough up the field after the firſt or ſecond year, is from ten to fifteen pounds; to which is commonly added about a buſhel of rye graſs ſeed. It was formerly, he ſays, conſidered improper to ſow graſs-ſeeds of any kind along with oats, barley, or other white-corn crops. This opinion, however, has been clearly and ſatisfactorily proved to have been ill founded, and muſt have been at firſt promulgated by thoſe who were better acquainted with the theory than with the practice of agriculture. Every practical farmer now knows," he adds, "that if a crop of graſs be the principal object in view, there is a greater chance of its proving abundant when the ſeeds are ſown with barley particularly, than when ſown alone. This fact is ſo completely eſtabliſhed, that there are, it is preſumed, few inſtances where the method above mentioned is ſtill adopted. The general practice is to ſow, not only red clover, but all other graſs-ſeeds, with oats or barley in the ſpring. When the ſeeds are ſown, which is uſually done as ſoon as the grain is harrowed in, the field is again gently harrowed, and afterwards rolled, ſo as to cover the ſeeds, and ſmooth the ſurface of the field, that the ſcythe may paſs eaſily over it the following ſeaſon. Red clover, when the ſeed is ſown along with, or rather immediately after, barley, and at the rate of twelve or fifteen pounds to the acre, frequently overtakes, or overtops, the crop of barley ſo much, as materially to injure it. Were the clover ſeeds not ſown till the barley had vegetated to the height of three or four inches, he thinks this loſs and inconvenience would in all probability be avoided; at the ſame time the crop of barley would rather be improved than injured by a light harrowing at that ſtage of its growth, while the clover-ſeeds would vegetate as freely, and the crop of graſs prove as abundant, as if the ſeeds had been ſown at an earlier period, or at the time the grain was put in. As it is an eſtabliſhed rule or regulation in many diſtricts, eſpecially in Scotland, for an entering tenant to pay the one who removes a certain ſum, as from 10*s.* to 20*s.* the acre, for liberty to ſow graſs-ſeeds along with the outgoing tenant's barley; it is fair to preſume, he conceives, that this rule has been eſtabliſhed on proper principles, and that the payment ſo made, is no more than an equitable compenſation for the injury which the removing tenant ſuſtains by granting this permiſſion. "If ſo," ſays Mr. Donaldſon, "the average loſs of 15*s.* the acre, which is incurred by ſowing red clover along with barley ſeed, muſt appear of conſiderable magnitude to thoſe who ſow a fourth, a fifth, or a ſixth part of their farms every year with barley and red clover-ſeeds. The method above ſuggeſted for obviating this loſs and inconvenience, cannot poſſibly be attended with any bad conſequences to either of the crops in queſtion; and as it would in all probability prevent this evil, which is ſo generally complained of, it certainly merits the conſideration of thoſe who, having repeatedly ſuſtained heavy loſſes from the failure of their crops of barley, are of courſe more immediately intereſted."

The practical writer we have firſt mentioned has remarked, that "on farms where there are kept large flocks of ſheep, there is an abſolute neceſſity of ſowing annually many acres of this graſs, that there may be no want of food for the flock during the ſummer months. For this reaſon, clover is often ſown on land that is improper for its cultivation; in which predicament may be ranked ſuch poor fields where the juices of the ground have been exhauſted by repeated crops of corn. But, though large burthens of clover cannot be expected from ſuch worn out ſoils, yet the farmer, in the circumſtances above alluded to, acts a prudent part in ſowing the ſeed, for this will conſiderably improve his grattens in the following autumn, and furniſh the ſheep with food during the firſt part of the winter; and if the clovers may not have taken ſufficiently thick to ſtand for a crop, or that the ground be intended to come in courſe for corn that year, or for a fallow, ſuch mode of huſbandry may be purſued without an apprehenſion of the leaſt damage to accrue from the growth of the clover. On theſe accounts, it will redound much to the intereſt of a farmer who keeps a large flock, not only to raiſe many acres of this graſs annually, with the expreſs view of reſerving it for a crop to ſupply the ſtock with green meat throughout the ſummer; but in particular caſes, as when from the abundance of the crop the ſeed is but of inferior value, or there is a probability of there being required on the farm a larger ſupply of ſheep-keeping than uſual, to ſow a ſprinkling of clover-ſeed in a variety of fields among the wheat, oats, and barley, though ſuch ground be intended for tillage the following ſpring."

It is added that "the beſt clover ſeed is that where the purple colour chiefly prevails, and which is moſt free from the ſeeds of weeds, of whatever kind. When clover is deſigned to ſtand for a crop, the beſt method of preparing the land for this uſe is to allow a liberal quantity of dung on the turnip fallow, and the turnip ſeed being thus ſown on fallows, properly conducted, will, in all likelihood, produce a good crop of that root; and if the ſpring ſhould turn out kindly, the turnips may be eaten off, and the ground reduced to a tilth for ſowing the oats and clover ſeed in March. Three buſhels of oats in this caſe is a proper quantity to the acre: if more ſeed were allowed, the crop from the extraordinary tillage beſtowed on the land would probably throw out too great a quantity of ſtraw ſo as to be early lodged, by which the welfare of the clover would be endangered. As it is of conſequence that the ground ſhould work kindly at the time of ſowing this and all other graſs ſeeds, the utmoſt care ſhould be taken to get it into a due preparation for that purpoſe; and as the turnip ground is frequently baked very hard by the treading of the ſheep in a wet winter, ſo that ſuch ground is apt to break up in large clods at the firſt ploughing in the ſpring: in this caſe, two ploughings will be required previous to ſowing the oats and clover, which will not only diſpoſe the field to work kindly, and to lie ſmooth and level, ſo that the ſmall fibrous roots of the clover will meet with leſs reſiſtance, and the graſs will form its ſucceeding ſhoots with greater facility; but this kindly diſpoſition of the ground at ſeed time, will enable the oats likewiſe more ſucceſsfully to withſtand the drought of the ſpring, or other accidents. As it is of eſſential conſequence that the clover ſeed ſhould be ſown in a bed of well pulverized earth, and at a time when the ground may be worked to the greateſt advantage with the harrow, care ſhould be taken to fix on a tolerably dry time for this work, otherwiſe much of the ſeed will not vegetate, and that which may grow will ſuſtain infinite prejudice: for in a wet ſeed time the ground becomes beaten down ſo very cloſe, that the ſeed is prevented from ſending forth tender fibres; and in conſequence from ſhooting forward with vigour; whence the crop languiſhes in its ſeveral progreſſive progreffive ftates, and fails to produce a return nearly adequate to what might have been expected from land in that improved ftate; and this fhows the neceffity of breaking up fuch ground which is meant to be fown with clover feed, in the early part of the fpring, that there may be time to give the field a fecond ploughing, if it fhould be found requifite; and hence alfo appears the neceffity of fowing the feed before the dry weather fets in, and this may generally be brought about, if the turnips are fed off by the latter end of February, or beginning of March. Though an early fowing, as fome time within the month of March, is by far the moft likely method of infuring a good crop of clover on thin foils, yet in the cafe above mentioned, there will be no time loft in waiting till the land has been twice ploughed, though from this circumftance, if the weather fhould prove unkindly, the feed time may be protracted till April, as it will be far more prudent to wait till that time, than to fow the feed in a rough and ill cultivated bed. Neither can fuch early fowing often be complied with on ftiff foils, as this ftubborn ground does never work kindly under the barrow, till the fpring is farther advanced, and always requires a fecond ploughing for the Lent corn, fo that the clover is rarely fown on thefe foils till the middle of April, and very frequently this bufinefs is procraftinated till May; but this fhould by no means be brought into a precedent; fince on moft grounds, as obferved before, the early fown clovers have a much fairer chance of fucceeding, than thofe which are fown later in the fpring feafon. The feeds of clover, being very fmall, require only a fuperficial covering, and the ufual method is to fow the clover previous to the laft harrowing of the oats, by which the feed will be introduced to a proper depth; and this method of tining the feed in with the harrows is, in his opinion, greatly to be preferred to putting it in with a bufh or only rolling in the feed, as is the practice with many people; for though this feed, being of a diminutive fize, will eafily take root, and if harrowed in at too great a depth beneath the furface, would be in danger of not coming up at all: yet there is a medium to be obferved, and the fowing of it previous to the crofs harrowing of the corn, appears, he fays, a more likely way of defending it from the cafualties of the weather, than the flight covering by a bufh or roller. Clover feed is often fown amongft green wheat in the fpring, and covered with the fmall harrows, and the ground afterwards rolled, except when the wheat is fo thin upon the ground, and fo loofe at the root, as not to admit of this practice, which fometimes happens; and in this cafe we muft content ourfelves with the ufe of the bufh-harrow and roll," as it would be dangerous to have recourfe to any other method.

It is well known that clover, in its infantine ftate, and before it has attained its rough leaf, is very apt to be eaten by the fly or flea, which is another reafon for fowing early, that the plants may get into rough leaf before the approach of dry weather; and this is likewife an argument for reducing the ground to the fineft poffible tilth, that this infect may not have fo proper a nidus to generate in; fince it is found by experience, that the fly or flea, which is the fame infect that preys on the feed leaf of the turnip, and on the firft fhoot of the hop, is more frequently met with, and commits more fatal depredations on ground that is rough and cloddy, than on thofe fields which have been reduced to a fine tilth by the harrow. There is, the fame writer fays, a very common error which farmers are apt to run into at clover feed time, by which they are often confiderable fufferers in the future crop; and this is, to fow a larger quantity of ground than they are able to harrow in the fame day, fo that if there happens a glut of rain, that they cannot get on their land till feveral days after it has been fown, the feed muft either lie uncovered, or a great part of the clover be torn up by the harrow after it has begun to vegetate. It is, he fays, a very ufual method for the feedfman to continue fowing clover or other grafs feeds in the afternoon after having fown the barley in the morning, by which management the farmer thinks he is gaining time, as this ground may be harrowed the next day with the odd horfes, whilft the team horfes are covering in the barley or oats. And were there a certainty of fine weather, this would doubtlefs be a very prudent and commendable practice; but as this is not to be depended on, it feems to him to be an experiment fraught with too much hazard, in fuffering a dozen or fixteen acres of clover ground to lie uncovered, which would be utterly fpoiled if wet weather fhould intervene, fo as to prevent it being harrowed within three or four days, a fpace of time fufficient for the feed to have ftricken root. Nor is this the only mifchief likely to follow from this practice; for the feeds of clover, as well as trefoil, being of a diminutive fize, their veffels foon become overcharged with moifture, and when this happens, great part of the feed will in courfe never vegetate; fo that on every account it feems to be highly imprudent to purfue this method, unlefs the weather be fuch as to promife a dry day or two, which however, in our infular fituation, and at this time of the year, can rarely be depended on with any degree of certainty.

It is obferved, that "though clover feed will grow at two years old, it is by far the moft fecure method, to fow that of the laft year, which is not only quicker in vegetating, but the plants likewife fhoot away with greater expedition, and fooner attain their rough leaf; a confideration of no fmall moment, fince the fly is fo peftilent an enemy to this grafs in its infantine ftate." It is always a matter of great importance, in thefe crops, to have well ripened frefh feed.

And it is further remarked, that, "in a dripping fummer, the clovers grow to a confiderable height amongft the corn, and in this cafe, the barley often fuffers after a wet and tedious harveft. Oats take lefs damage by wet, and wheat, being reaped, may generally be cut above the clover. When it happens that the clover grows to fo large a head during the fummer, the ftubbles will be found to produce great ftore of food in the autumn, either for horfes or cows, efpecially if warm dripping weather fhould happen at that time: and when the large cattle are removed, their places may be fupplied with fheep, and by this management a very confiderable advantage is gained; for thus the working horfes are maintained in good heart at that time when there will be but a fmall fupply of green meat remaining, the cows will be fupplied with a wholefome food that will caufe them to yield abundance of milk, and the fatting cattle will be greatly improved in flefh: old ewes, or indeed fatting fheep of whatever denomination, will thrive in this keeping, and if they fhould not be perfectly ready for the butcher when taken out at Michaelmas, will however be in much better condition to be driven into the turnip field, than if they had at that time been bare of flefh: fuch fatting lambs as are yet unfold, may likewife be brought into flefh on thefe young clovers. In fhort, among the various advantages to be derived from the cultivation of this grafs, it is none of the leaft, that in the autumn after it is fown, it will produce a fupply of valuable food, which may be turned to fo many different purpofes, and, with the help of the faintfoin lays, preferve the turnips untouched till Chriftmas, if the early part of the winter fhould prove mild and open.

 To

To such farmers who pursue the mode of suckling lambs, the young clovers are exceedingly useful, affording a valuable pasture for the ewes, and causing them to spring abundantly in their milk. But with all these advantages, there is some discretion to be used in the feeding young clovers, both with respect to the cattle and the grass. Beasts which are of the ruminant tribe, it is well known, are apt to feed with that greediness and avidity when turned on succulent pasture, as to occasion a repletion; which, among the farmers, is technically called *hoving* or *blowing*. Many sorts of food will occasion this malady, and none has a greater tendency towards it than clover; for which reason the horned cattle should not be turned into the field till towards nine or ten o'clock in the morning, especially in wet weather; and whilst they are feeding, they ought to be carefully watched, though there will be less need of these precautions when they have been some few days accustomed to the food, and have eaten down the rankest part of the grass. The like precautions it will be necessary to take with respect to sheep, when they are depastured with the cows; but if these latter are not permitted to graze on the clovers till the large cattle shall be removed, they will run little or no risk of hoving." See HOVEN.

It may be necessary also to observe, that "this, as well as other sown grasses, is much injured by being depastured too low. It will be necessary with respect to feeding clovers in this period of their growth, to take the stock off them before the close of the year, as it would be a specimen of very ill husbandry, Mr. Bannister thinks, to suffer the cattle to remain in the field after Christmas, at which time the clover should be left a tolerable height; for if eaten down too close, a great part of it would be destroyed, and the spring shoot would be languishing and weakly, which should never be the case in this sort of grass.
